This project will determine the existing presence and balances of microbial populations. These determinations will be made by use of standard culture techniques and membrane filter-fluorescent antibody method at selected sampling stations in Hartwell Reservoir. Under laboratory conditions, the stability of relative populations and balances will be tested. The effects on populations and balances produced by selective additions of pollutants, will be determined. Attempts will be made to remove pollutants and reverse such pollution effects by controlled addition of selected microbial populations.

2.0795, FEASIBILITY STUDY OF AERIAL PHOTOGRAPHY FOR DETERMINING PHYSICAL FEATURES OF TIDELAND & ESTUARINE AREAS, BEAUFORT CO., SOUTH CAROLINA
C.P. GUESS, State Water Resour. Commission, *Columbia, South Carolina* 29201

This study is to determine the feasibility of using aerial photography (and photo interpretation) to delineate significant physical characteristics of tideland estuarine areas.

This project will consist of making an aerial survey of designated tideland and estuarine areas of Beaufort County, South Carolina, and interpreting the photographs. Survey and related activities shall include: 1. The running of vertical and horizontal control into the area; 2. The reduction of tidal gage data to the Coast and Geodetic Survey Datum; 3. The establishment of tidal bench marks as required; 4. The performance of aerial photography with infra-red black and white film at mean high tide and also of infra-red color, pan-chromatic, standard and minus blue color film; 5. The preparation of a tideland base map showing cultural detail, edge of marsh, drainage, etc., but no final shore lines; 6. The addition of the mean high tide line to the base maps by various procedures basic to the purpose of the pilot project; 7. The field verification and checking of the various procedures used to delineate the mean high water shoreline, and the determination of the most suitable procedures for the different shoreline conditions; 8. Plotting of source and apparent extent of pollution on the base maps; 9. Feasibility of navigation channel bottom mapping and the addition of hydrographic contours to the base maps; 10. The investigation of the technical feasibility and economics of a land use study including the delineation of the limits of the salt water flood plain zone; 11. Narrative explaining procedures, problems, legal interpretation, limitations, and definitive estimate of the cost and time required to undertake the study on a statewide basis; and 12. Maps show-

ing the mean high water line as established by the survey, drainage pattern.

SUPPORTED BY Coastal Plains Regional Commission

2.0796, BACTERIOLOGICAL WATER QUALITY ANALYSES OF METHODS FOR DETECTING FECAL POLLUTION

P.R. MIDDAUGH, South Dakota State University, School of Agriculture, *Brookings, South Dakota* 57006

The proposed research involves laboratory and field investigations to improve the specificity, speed and reliability of bacteriological methods for determining kinds and number of fecal bacteria in surface water resources. The main objective is to develop bacteriological methods to distinguish between human versus animal sources of pollution by fecal indicator and pathogenic bacteria.

Laboratory investigations: 1. Fecal bacteria isolated from water samples would be used to evaluate modified bacteriological methods designed to detect differences in kinds and numbers of coliform, fecal coliform and especially fecal streptococci of human versus animal sources. 2. Samples of polluted surface waters would be stored in controlled laboratory environments to determine the relative rates of die-off coliform, fecal coliform, fecal streptococci and fecal pathogens e. g., salmonellae.

Field investigations would employ the bacteriological methods to determine the ratio of numbers of fecal coliforms and fecal streptococci in the same sample of selected stream and lake waters. This ratio has been reported to distinguish between human and animal fecal bacteria.

Laboratory and field data would be correlated for practical application in attempts to trace sources of fecal bacterial pollution of surface water resources and to attempt to distinguish between human and animal wastes with emphasis on farm animal wastes.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0797, CHEMICAL, PHYSICAL, AND BIOLOGICAL DYNAMICS OF NORTHERN PRAIRIE LAKES

J.G. NICKUM, South Dakota State University, School of Agriculture, *Brookings, South Dakota* 57006

The research plan proposes to make it possible to describe the chemical, physical, and biological dynamics of heretofore unstudied lakes. This will provide information concerning the relationship between land use and water quality of lakes.

The project will study the present, the seasonal variation, and the possible year to year variation of water quality. This will be accomplished by biweekly sampling during June, July, and August, and monthly throughout the remainder of the year. In addition, samples of water flowing into the lakes will be taken whenever rainfall is sufficient to cause a runoff into each lake.

The chemical content of the water will receive special attention in that the levels of various chemical biocides in the ecosystem will be determined. Pesticide residues will include endrin, dieldrin, aldrin, heptachlor, heptachlor epoxide, DDT, DDD, DDE, lindane, toxaphene, and the chlorophenoxy compounds. Pesticide residues will be extracted from five types of materials including water, mud, plant material, small aquatic animals and fish.

The field data will be used to provide information concerning the relationship between land use and the dynamics of a lake.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0798, INVESTIGATION OF LAKE WATER QUALITY IN EASTERN SOUTH DAKOTA WITH REMOTE SENSING TECHNIQUES

F.A. SCHMER, South Dakota State University, Remote Sensing Institute, *Brookings, South Dakota* 57006

This proposed research is directed toward hydrologic research, utilizing remote sensing techniques, in eastern South Dakota with special emphasis on geology and its relationship to lake water quality. The specific objectives of this research are: 1. To determine the applicability of available remote sensing techniques for evaluation and monitoring the quality of lake water in eastern South Dakota. 2. To accomplish geological mapping, by utilizing remote sensing techniques combined with ground truth information, of 50 square miles surrounding 10 lakes in eastern South Dakota. 3. To relate variations of water quality in eastern South Dakota lakes to climatic conditions, seasons, changes in water level, and geology and hydrology of the surrounding area.

Remote sensing aircraft will be flown diurnally and seasonally over selected transects across the lakes and surrounding area under investigation. Flight schedules will take advantage of the time dependent characteristics and phenomena that may provide information for determining lake water quality and the causes of lake water quality fluctuations. Ground truth data including geologic information and water quality data will be collected.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0799, PHYSICAL STREAM INVENTORY OF THE MAJOR WATERSHEDS IN THE BLACK HILLS

R.D. GLOVER, State Dept. of Game Fish & Pk., *Pierre, South Dakota* 57501

Objectives: To document the factors responsible for the degradation of water quality and quantity in lakes and streams of the Black Hills.

Procedures: The major watersheds will be physically inventoried from their headwaters to the point at which they are no longer considered an integral portion of the Black Hills fishery. The inventory will involve walking the streams and recording observations on factors affecting water quality and quantity. No chemical or biological tests will be conducted. Observations will include: 1. Land ownership - private, state or federal, 2. Land use i.e. forestry products, cropland, grazing, etc., 3. Stream bank cover, 4. Pollution sources i.e. mining, homes, stock-yards, road grades, sewage treatment plants, etc., 5. Natural obstructions in the stream i.e. beaver dams, 6. Fisherman access to streams, 7. Topography.

Additional observations will be added according to need. Improvement recommendations will be made. Streams will be identified by proximity to their headwaters and subdivided into 4 sections A,B,C,D, i.e. Rapid Creek 1-A, would be the headwaters; 1-B the next one-fourth mile, etc. Rapid Creek, 2-A, would be the first quarter mile section of stream in the third mile below the headwaters.

The following is a tentative order of inventory: 1. Rapid Creek, 2. Spring Creek, 3. Castle Creek, 4. Boxelder Creek, 5. Spearfish Creek, 6. Elk Creek, 7. Battle Creek, 8. French Creek, 9. Fall River, 10. Cascade Creek, 11. Bear Butte Creek, 12. Englewood Creek, 13. False Bottom Creek, 14. Crow Creek, 15. Iron Creek (south), 16. Grace Coolidge Ck.

2.0800, PREOPERATIONAL AND OPERATIONAL RESERVOIR MONITORING - BROWNS FERRY NUCLEAR PLANT

B.B. CARROL, U.S. Tennessee Valley Auth., *Knoxville, Tennessee* 37902

The objective of this segment of these investigations is to determine species composition and relative abundance of fish in 67,000- acre Wheeler Reservoir prior to and following the introduction of heated cooling water from the Browns Ferry Nuclear Plant.

Fish samples are taken on a regular basis by electroshocking, gill nets, trap nets, and rotenone to evaluate relative abundance, diversity, density, growth, movement, food, and for radiological analyses, before and after the plant becomes operational. The plan has been amended to include a study of the production and survival of larval game fish in the littoral area above the plant before and following plant start up to appraise possible losses through condensers during operation.

Data for ten quarterly preoperational sampling periods have been collected and reported.

SUPPORTED BY U.S. Tennessee Valley Auth.

2.0801, SURVIVAL OF INDICATOR ORGANISMS AND ENTERIC BACTERIA IN WATER
J.D. WOMACK, Univ. of Tennessee, School of Engineering, *Knoxville, Tennessee* 37916

The proposed work involves a study of indicator organisms and enteric bacteria in three areas. The survival of coliform bacteria and fecal Streptococci will be compared with other organisms found in the intestinal tract of man and in contaminated waters. Especial attention will be given to the enteric pathogens in the Salmonella group responsible for food intoxication. The effects of the employment of a new secondary treatment plant by the city of Knoxville, Tennessee on the survival and persistence of indicator organisms in Fort Loudoun Lake will be investigated. Also to be examined in this project is the effect of nitrogen nutrient levels on the growth and persistence of fecal Streptococci in lake water.

Field and laboratory studies will be conducted to measure the numbers of indicator organisms surviving in the lake. Time of flow will be determined with dye tracer techniques. Diffusion cell techniques will be employed to reveal the survival characteristics of enteric pathogens and naturally occurring pathogens will be investigated.

Data already in hand on the 'before' characteristics of Fort Loudoun Lake will be correlated with new information on survival of indicator organisms after the new secondary plant is brought on the line. This data will be taken from samples taken from the lake on a time-of-flow basis using dye tracer techniques.

The natural nitrogen nutrient level variations in a small lake will be related to the survival and growth of fecal Streptococci. Laboratory studies under controlled conditions will also be performed.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0802, EFFECTS OF INDUSTRIAL EFFLUENTS ON PRIMARY PHYTOPLANKTON INDICATORS
B.R. STAUB, Christian Brothers College, Undergradute School, *Memphis, Tennessee* 38104

The purpose of the study is to select feasible indicator organisms from the completed sampling results of Project B004-Tenn on the natural aquatic communities of the Memphis area. Means of interpreting the community or population response of these phytoplankters will be sought in order to recognize the kind(s) or degree(s) of pollution involved. Diatoms and other primary producers will be investigated. Pure and mixed cultures will be utilized, originating from the Mississippi and Wolf Rivers and Nonconnah Creek. Statistical analyses using diversity index, maximum and minimum diversity, and redundancy will be pursued. The ion exchange properties of these selected organisms will be studied using labeled pollutants to determine adsorption isotherms, distribution coefficients, and rates of reaction so as to interpret the nature of the uptake.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0803, GEOHYDROLOGY OF SHALLOW AQUIFERS IN HENRY AND WEAKLEY COUNTIES, TENNESSEE
J. WILSON, U.S. Dept. of the Interior, Geological Survey, *Nashville, Tennessee* 37203

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of Tennessee.

Purpose - To determine the cause or source of contamination of ground water and to appraise the shallow water-bearing formations.

Methods - An inventory of representative wells will be made. Water from wells will be sampled and analyzed to determine the bacteriological and chemical quality of ground waters. Test holes will be augered, observation wells will be constructed and pumping tests will be performed to define the areal extent and water bearing characteristics of shallow aquifers.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0804, INTERRELATIONSHIP OF METEOROLOGICAL FACTORS AND THERMAL PLUMES
P.D. KROLAK, Vanderbilt University, School of Engineering, *Nashville, Tennessee* 37203

An analysis of the random character of meteorological variables will be carried out. Time series analysis of the requisite data have been undertaken. The correlation of the various parameters with each other will be made. A sensitivity analysis of the results will be undertaken. For predictive purposes, to determine the maximum and minimum degrees of cooling of the heated discharge waters, a means of generating operational meteorological data similar to the methods of establishing an operational hydrology will be determined. It will then be possible to determine on a statistical basis the degree of impairment of the water resource to be expected per unit time.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.0805, TEMPERATURE DISTRIBUTIONS RESULTING FROM COOLING WATER DISCHARGES
E.M. POLK, Vanderbilt University, School of Engineering, *Nashville, Tennessee* 37203

Additional field temperature distribution data for both the mixed and stratified cases of thermal discharges below power plants are necessary to adequately test proposed distribution models or develop new ones. A resurvey of the Johnsonville and Bull Run electric generating plants of the Tennessee Valley Authority will be carried out as they have both the mixed and the stratified categories which depend upon the flow levels in the receiving reservoirs. The John Sevier TVA site and others will also be studied this year. The non-conservative type of temperature distribution has not yet been studied. The major problem is to find plants which create a 10 degree F or higher mixed temperature rise in the receiving stream. The field work will include a variety of site geometries, river flow conditions, and meteorological conditions. Four of the sites tested to date have had densimetric Froude numbers of 0.257 to 0.970. The fifth site had a Froude number greater than one. During the survey of new sites, the densimetric Froude numbers will be determined. Sites will be sought that have a distribution of Froude numbers that are similar to the distribution Froude numbers at the sites surveyed. Theoretical work has been proceeding on wedges, jets, and diffusion models. The field data will enable evaluation of the mathematical models and provide guidelines for improving them. Laboratory studies have been carried out to determine entrainment coefficients, critical Froude numbers, and jet drag coefficients. Field data will be necessary to provide final verification.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.0806, TEMPERATURE INCREASES BELOW DAMS
E.L. THACKSTON, Vanderbilt University, School of Engineering, *Nashville, Tennessee* 37203

Because mixed temperature rises in streams below thermal power plants are so small, the inverse of the problem, the heating up of cold hypolimnetic waters in streams might better be utilized to determine the individual components of the heat budget. The same physical mechanisms which contribute to the cooling of heated waters should also contribute to the heating of cooled waters. Therefore, we propose to test discharges from the hypolimnion below the dams. There are few sites at steam plants where the mixed river temperature is sufficiently above equilibrium to provide heat transfer rates which can be measured accurately. However, there are several hydroplants where the discharge temperature during the summer is as much as 40 degrees F below equilibrium temperatures. This should provide a fruitful opportunity for study, since the heat transfer mechanisms are essentially the same for heating and cooling.

The site chosen for this year's preliminary study is below Wolf Creek Dam on the Cumberland River in south-central Kentucky. There is approximately 80 miles of open river below the

dam to the first major tributary, and the outflow stays below 50 degrees F all summer. It is proposed to tag a slug of cold water within a fairly uniform discharge and follow it downstream for two days with drifting boats carrying weather equipment. The temperature of the water will be measured continuously and compared with predicted values computed from the measured weather data. A fluorometer mounted on one of the boats will be used to locate and follow the center of the dye cloud used to identify the slug of water to be monitored. Weather instruments will also be placed on the bank nearby. Data from the nearest U. S. Weather Bureau station will be tested for its ability to predict the rate of warming of the water at the river. This project was begun in August 1969 and is scheduled for completion in September 1971.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0807, THE QUANTITATIVE DETERMINATION OF LEAD IN LAKE WATER VIA ATOMIC ABSORPTION SPECTROPHOTOMETER
H.D. MCAFEE, Univ. of Texas, Undergraduate School, *Arlington, Texas* 76010

The object of this work was to determine the adaptability of atomic absorption spectrophotometric techniques to the study of water pollution in terms of lead, cadmium, and other heavy metals. It was determined that these techniques could indeed be used in the detection of lead in trace (less than 0.2 mg/l) amounts.

The first series of tests were made on water from a lake which is used for municipal supply and for recreational purposes. Contamination of the water by lead tetraethyl was not apparent even though boat traffic on the lake is quite heavy. More tests will need be made in order to insure more complete coverage of the lake.

It is highly probable that this type of instrument can be used to help establish the quality of drinking water supplies. Furthermore, since it is desirable that heavy metal ions not be discharged into ordinary sewage treatment plants, this instrument could be employed by industrial plants and public health personnel to check on the quality of plant effluents.

Study to be extended to oxidation ponds.

SUPPORTED BY University of Texas - Austin

2.0808, SIMULATION OF WATER QUALITY IN STREAMS AND CANALS
W.A. WHITE, Frank D. Masch & Associates, *Austin, Texas*

Objective: To develop a set of interrelated water quality models capable of routing the following water quality parameters through a branching stream or canal system: 1. Temperature 2. Biochemical Oxygen Demand/Dissolved Oxygen, and 3. Conservative Minerals.

Approach: A set of interrelated quality models is developed for the prediction of the temporal and spatial distribution of temperature, biochemical oxygen demand/dissolved oxygen, and conservative minerals within a river basin. The governing differential equation is solved by an implicit-finite-difference technique under the assumption that advection along the primary axis of flow (longitudinal axis of the stream reaches) is the primary mode of transport. The models are verified with field data from a portion of a river basin containing multiple headwater sources, waste loadings, and branching streams.

SUPPORTED BY Texas State Government - Austin

2.0809, APPLICATION OF STOCHASTIC TECHNIQUES TO WATER QUALITY DATA ANALYSIS
A.O. WEISS, State Water Development Board, *Austin, Texas* 78711

Objective: To evaluate the feasibility of using stochastic techniques for generating conservative water quality parameters for deterministic and stochastically generated streamflow sequences.

Approach: A random component will be added to deterministically computed conservative water quality parameters (dissolved solids, chloride, and sulfate) to simulate the randomness inherent in measured water quality data. This technique will be capable of generating water quality parameters to correspond to discharges generated by either deterministic and statistical streamflow simulation models. The primary simulation model will be a statistical fill-in procedure in which unfilled data sets (water quality) will be filled-in using a complete data set (discharges) as reference. The fill-in model will use available water quality data to establish the population statistics and then will extend the record to the length desired, maintaining these statistics during the extension.

SUPPORTED BY Texas State Government - Austin

2.0810, MULTI-BASIN WATER QUALITY SIMULATION
W.A. WHITE, State Water Development Board, *Austin, Texas* 78711

Objective: To develop a computerized simulation technique for application to the analysis of quality constituents (conservative materials) in transfer links of a system of reservoirs and interconnecting transfer canals and river reaches such as the Trans Texas Division of the proposed Texas Water System.

Approach: A conservative mineral routing model will be developed to interface with existing multi-basin planning model (SIM-III and SIMYLD- I) which simulates the hydraulics of an interconnected network of reservoirs, pump canals, and river reaches. Specific goals are to: (1) insure that the various plans analyzed by SIM-III and SIMYLD-I are capable of delivering water at quality levels suitable for all intended uses, (2) evaluate the effects that various prespecified quality standards have on the cost of the water delivered, and (3) evaluate the effects that urbanization and other land use changes have on the quality levels of the streams and of the reservoirs into which streams flow.

SUPPORTED BY Texas State Government - Austin

2.0811, URBAN HYDROLOGY STUDY - SAN ANTONIO, TEXAS
E.E. SCHROEDER, U.S. Dept. of the Interior, Geological Survey, *Austin, Texas* 78701

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of Texas.

Purpose: To provide data for a logical approach to flood-zoning and flood-protection problems, and to analyze the effects of progressive urbanization on the runoff. Data will also be useful in design of storm sewers, culverts, and bridges.

Methods: An adequate sampling will be made of data with respect to flood discharge as affected by time, variations in rainfall through climatic cycles, size of area, and degree of urbanization of area. This sampling will be accomplished by installation of streamflow stations, crest-stage stations, and rain gages at appropriate locations. The instrumentation will be done on pairs of small drainage basins within the metropolitan area. One basin of a pair will be chosen to represent urbanized conditions, the other will represent the undeveloped conditions. In so far as possible, the pairs of basins will be chosen so that the other factors such as geology, topography, and size will be equal.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0812, LIMNOLOGICAL INVESTIGATIONS OF TEXAS IMPOUNDMENTS FOR WATER QUALITY MANAGEMENT PURPOSES
E.G. FRUH, Univ. of Texas, School of Engineering, *Austin, Texas* 78712

The seasonal change in water quality parameters such as dissolved oxygen, pH, precipitates, nutrients, and microorganisms will be measured in seven sub-tropical impoundments within a 150 mile reach of the Lower Colorado near Austin. Field surveys will be conducted below the impoundments to determine the effect of releases on the water quality of the downstream impoundment. The data will serve as a model for future river systems which have been transformed from a free-flowing river to a series of slack-water pools with intermittent river reaches.

In the last year of the project, major emphasis will be placed on determining what effect additions of different quality waters

(through a diversion project or pollution) would have on the water quality of the impoundments. Various nutrient enrichment studies will be conducted under different temperature and light conditions. Carbon- 14 bioassay techniques will be utilized to determine limiting nutrient concentrations. Similar tests will be conducted using additions of river waters most likely to be diverted to the Texas Colorado River Basin in any future state water plan.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0813, MODEL RIVER SYSTEM STUDIES
E.F. GLOYNA, Univ. of Texas, School of Engineering, *Austin, Texas* 78712

The objective of this project is to provide information concerning the behavior and effects of radionuclides released to aquatic systems during continuous low-level discharge conditions or accidental high- level spills from reactor, waste processing, or laboratory sites. This information will be used to develop a reliable mathematical model which, when given several factors easily measured in the systems, will facilitate an evaluation of the actual or potential impact of a particular facility on safety and public health. A model river system consisting of a flume 200 ft. long, 2.5 ft. wide and 2 ft. deep has been and is being used to isolate and study variables such as the change in transport of radionuclides as caused by induced pollutional loads, clay suspensions, pH variations, chemical concentrations, and the dynamics of radionuclide transfer from water to plants and sediments. Specific emphasis is given to determining the behavior of Co-58, Sr-85, Cs-137, Zn-65, and Cr-51. All flume experiments are preceded by detailed laboratory and aquaria investigations.

A series of experiments have been conducted to determine the delay in transport of radionuclides caused by the interaction between flowing water and bed sediments. The relative concentration of radionuclides on the surface of the bottom sediments to that in the bed sediment was found to be a function of the depth of bed sediment from the surface, diffusion coefficient in water and time after migration started. A computer program has been developed and tested through prediction of hydraulic dispersion uptake and release of radionuclides by bottom sediments and plants in a flowing flume, simulating river processes. This program is adapted for prediction of radionuclides transport in a real river.

SUPPORTED BY U.S. Atomic Energy Commission

2.0814, INSTRUMENTATION FOR ENGINEERING MANAGEMENT OF A MULTI-PURPOSE RIVER BASIN SYSTEM
E.F. GLOYNA, Univ. of Texas, Ctr. Res. in Water Resources, *Austin, Texas* 78712

The proposed research plan involves various conceptual interaction studies to determine the data acquisition and monitoring instrumentation system requirements on a major, multi-purpose river basin system in order to achieve the extremely high degree of water quality and water multi-use management which is envisaged for this engineering operation.

The specific area of the study is the Trinity River Canalization and tributary projects which are part of the comprehensive basin program.

The studies will evaluate the performance of specific water quality monitoring networks, the status of automation in data transmission recording, storage and retrieval and also sensing and detecting devices as applied to stream gaging, flood routing, navigation lockages, and water quality sampling. Hence, the studies will evaluate the major elements of information engineering with the view toward developing feasible applications for the efficient operation and management of comprehensive, multi-purpose water system.

These factors will be explored in detail, including the economics of the instrumentation system.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0815, PRECISION RATIO GAS-SOURCE MASS SPECTROMETER
W.R. MUEHLBERGER, Univ. of Texas, School of Arts, *Austin, Texas* 78712

The precision ratio gas-source mass spectrometer will be used in the determination of C13/C12,O18/O16 and D/H ratios in the following selected studies. D/H chemistry of natural waters and hydrated minerals as indicators of carbonate and silicate deposition and diagenesis, specifically: 1) D/H chemistry of bauxite minerals and its bearing on the origin of bauxites. 2) D/H chemistry of clays in Baffin Bay, Texas, a hypersaline lagoon, and its bearing on the recent history of the bay, and clay diagenesis. 3) Isotopic chemistry of selected organic compounds, Baffin Bay, Texas. Interaction of organic compounds, particularly fatty acids, and carbonate sediments, and diagenesis of organic compounds. 4) Carbon, oxygen, and hydrogen isotope studies of natural waters and recent carbonate and sulfate minerals from the Persian Gulf, and 5) Biogeochemistry of recent oysters, Texas coast, and determination of the history of sedimentation (including pollution) in Texas bays.

SUPPORTED BY U.S. National Science Foundation

2.0816, MACROBENTHOS AS INDICATORS OF ECOLOGICAL CHANGE
R.C. HARREL, Lamar State Coll. of Technol., School of Science, *Beaumont, Texas* 77704

The objective of this project is to correlate community structure of benthic macroinvertebrate with ecological changes in a 30 mile section of the lower Neches River.

The resulting information could be used to predict ecological effects of river basin development, and serve as a reference for future studies.

Physico-chemical conditions will be measured according to standard methods. Total oxygen demand will be made with an Ionic Total Oxygen Demand Analyzer by the Chemistry Department. Macrobenthos will be collected by dredge and artificial substrate samplers. Community structure will be determined in terms of numbers of species and individuals, indicator organisms, and diversity indices.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0817, THE MOLECULAR NATURE OF ORGANIC WASTE REMOVAL PATTERNS
W.B. DAVIS, Texas A & M University System, School of Engineering, *College Station, Texas* 77843

The objectives of this project are: 1. To investigate the behavior of organic compounds in activated sludge systems. 2. To investigate the use of analytical techniques including total organic carbon and gas chromatography in the characterization of natural waters with regard to identification of organic components.

In accordance with stated objectives, the behavior of representative organic chemicals will be investigated with regard to (a) rate and extent of removal from solution, (b) characterization of intermediate products in solution, (c) effects of molecular structure, and (d) interference effects in multi-component systems. All analytical data will be catalogued for reference value. Work will be oriented in the following direction: 1. Chemical: Development of analytical techniques and testing of substrate response in mixed culture batch reactors. 2. Engineering: Application of continuous treatment design innovations to multi-component systems of unusual response characteristics. 3. Microbiological: Isolation of species and relation of species predominance to substrate characteristics.

2.0818, ELECTRICAL LOGGING IN AQUATIC ENVIRONMENTS
W.E. SWEET, Texas A & M University System, Sea Grant Program Office, *College Station, Texas* 77843

2. WATER QUALITY

This project is designed to a) develop quantitative in situ and laboratory electrical logging hardware and technique, b) define the relationship between the electrical properties and the chemical, physical, and engineering properties of recent sediments, and c) result in computer models capable of reducing the electrical measurements to a variety of desired parameters. These techniques will provide a quick, accurate and inexpensive means of making sediment distribution and sediment property maps useful in pollution control work, offshore foundation work, and offshore mining. The costly and time consuming coring programs now used for such work can be vastly augmented and, in many cases, replaced by electrical logging.

2.0819, REMOTE SENSING - TEKTITE, VIRGIN ISLANDS

L.E. GARRISON, U.S. Dept. of the Interior, Geological Survey, *Corpus Christi, Texas* 78411

States to which project pertains: Puerto Rico - Virgin Islands.

The U. S. Geological Survey participated in the man-in-the-sea experiment Tektite I and anticipates participation in Tektite II during calendar year 1970. These experiments are conducted in tropical waters off St. John in the U.S. Virgin Islands. Inasmuch as they require a considerable amount of seafloor mapping, the experiments provide an excellent opportunity to combine observations from space with a man-in- the-sea program, and to evaluate the use of remote sensing in the study of the tropical reef environment.

The recent population explosion of 'Crown of Thorns' starfish and consequent rapid destruction of segments of reefs indicates the necessity of monitoring reef areas. Satellite observations spaced widely in time may provide early warning data on gross changes resulting from removal of beach and nearshore sand for building purposes, from pollution of nearshore waters or from basic changes in life forms.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0820, ION SELECTIVE ELECTROCHEMICAL SENSORS

I. TRACHTENBERG, Texas Instruments Incorporated, *Dallas, Texas* 75222

Continued investigations of ion-selective electrochemical sensors have demonstrated that several of these sensors can be used in continuous monitoring of a wide variety of polluted, saline, and brackish waters. The current investigation places particular emphasis on Ca, Mg, Fe(3), Mn and SO4 ions. New solid state sensors have been developed which show considerable promise for monitoring Ca, Mg, and Fe(3) ions. Emphasis is currently directed to novel material systems for use as ion-selective sensors. Nonoxide glasses with varying dopants have proved useful sensor material. Doped semiconductors have exhibited a variety of responses, but increased selectivity requires additional investigations of the kind and amount of dopant and the doping process used to make the material. Doped non-semiconductor single crystals will also be prepared and tested as sensor materials. Sensor materials will be used to construct sensors in electrode and/or membrane configuration. Sensors will be evaluated for selectivity and sensitivity, particularly in terms of interferences and limits of detectability.

SUPPORTED BY U.S. Dept. of Interior - Off. Saline Water

2.0821, VIRUSES IN SURFACE WATERS -DEVELOPMENT AND APPLICATION OF NEW CONCENTRATION METHODS

J.L. MELNICK, Baylor University, School of Medicine, *Houston, Texas*

The isolation of viruses from natural waters has been carried out usually with relatively crude and insensitive procedures (literature reviewed in Transmission of Viruses by the Water Route, edited by G. Berg, 1966). Recently this laboratory has developed new methods for detection of small amounts of virus in large volumes of sewage and other natural waters. These methods consist of the adsorption of viruses to and elution from (a) insoluble salts, (b) cellulose membranes, and (c) insoluble polyelectrolytes.

Under this grant, these studies will now be expanded toward development of field equipment for clarification of large volumes of surface waters prior to virus isolation, and for concentration of viruses in the field. This will avoid the receipt and handling of 100- gallon samples in the laboratory, permitting instead a very small and highly concentrated sample to be easily transported to a virus testing center to be assayed for its virus content. The methods developed will be applied in comparative testing for isolation of viruses such as polio viruses, echo viruses, and coxsackie viruses. Water purification steps in use or under consideration will be monitored as to their effectiveness in removing viruses that infect human beings.

2.0822, A MODEL RELATING WATER QUALITY VEGETATIONAL STRUCTURE AND URBANIZATION IN THE SAN JACINTO RIVER BASIN

D.L. JAMESON, Univ. of Houston, Graduate School, *Houston, Texas* 77004

We propose to analyze the correlation between vegetational structure, amount and kind of land utilization urbanization and the chemical and biological measures of water quality in the San Jacinto River Basin, Texas. The initial parameters will be obtained from government documents, reports already available or currently obtained (weather and hydrographic stations). These measures are assumed to be available to any metropolitan region which should give the model structural generality. Principal component analysis will be used for data reduction. Canonical correlation analysis will be used to obtain a preliminary estimate of the significant parameters. Multiple discriminant analysis will be used to identify the significant variables correlated with specific water quality stations. The data from these analyses will be used to construct a model which will characterize the present situation. The parameters of this model will then be manipulated with simulation programs in computers to attempt to predict the course and nature of water quality changes during the continued expansion of urbanization in the vicinity of Houston, Texas.

2.0823, STABLE ISOTOPE VARIATIONS IN BIOGEOCHEMICAL SYSTEMS

P.L. PARKER, Univ. of Texas, Graduate School, *Port Aransas, Texas* 78373

This is a continuation of NSF Grant GA-911 and it is planned to extend the research already done on ways to use measured variations in stable carbon and oxygen isotope ratios to solve problems concerning the flow of these elements in biogeochemical systems. These studies will be extended to stable nitrogen isotopes. Such biogeochemical systems will include rivers, lakes, marine bays and near-shore Gulf of Mexico, as well as single species of organisms, sewage systems and industrial plants.

The stable isotope ratios, especially of carbon, of the dissolved organic matter in natural and polluted systems will be studied as possible markers or tracers for both pollution and natural events.

The stable carbon isotope ratios of a large number of organic molecules isolated from living organisms and from recent and ancient sediments will be measured with the purpose of establishing chemical precursor-product relationships for these molecules.

Isotope fractionation in the biological cycle of oxygen will be investigated. These will include dissolved O2 as well as oxygen containing organic compounds.

2.0824, DEVELOPMENT OF SAMPLE PREPARATION METHODS FOR ANALYSIS OF MARINE ORGANISMS

H.C. MCKEE, Southwest Research Institute, *San Antonio, Texas* 78228

In this program, methods of sample preparation will be developed for processing, extracting, purifying, and concentrating specific chemical pollutants absorbed and retained by marine organisms so that chemical analysis to measure contaminants can be carried out. These methods, in turn, will be useful in the development and application of new techniques for water quality monitoring based on the analysis of marine organisms.

It is known from previous work that many species of marine life absorb various impurities from the water in which they live. Marine specimens can then be analyzed to identify and measure contaminants, even though concentration of contaminants in the water may be below the limit of detection of even the most sensitive analytical methods. In some cases, the results of such analyses provide a more direct indication of the effects of contaminants on marine life than measurements performed on water samples, especially where cumulative effects may occur over a period of time.

This program is based on a background of experience in trace analysis which has been developed over a period of many years. Methods are now available to measure trace materials in the parts per million and parts per billion range using a great variety of samples. In specific instances, these techniques have been used to measure trace contaminants absorbed and concentrated by fish and other marine organisms. These methods will be modified as necessary to provide appropriate techniques for monitoring water quality by measuring absorbed contaminants in various types of marine life.

2.0826, GEOCHEMISTRY OF WATERS OF THE HOG CREEK BASIN - HAMILTON, CORYELL, AND BOSQUE COUNTIES, TEXAS
T.H. MOORE, Baylor University, Graduate School, *Waco, Texas* 76703

The purpose of this study was to determine the change in water quality from the time it falls as rain near the headwaters of Hog Creek, Bosque County, until it becomes part of surface flow, about 19 miles downstream along the stream course of Hog Creek. Chemical tests were used to determine the quality of rainwater, spring water, and runoff. Special attention was given to waters which drain from farm lands, to determine if fertilizers have any effect on the quality of water in Hog Creek. Runoff water from each of the formations which crop out in the basin area was sampled to determine effect on the stream. The primary aquifer, the Edwards Limestone, was listed to determine chemical composition. A study of the structure of the Edwards Limestone was made to determine how large an area was drained by the aquifer to flow into Hog Creek as spring water. An effort was made to see if the length of time the water remained in the aquifer had any effect on the quality of water. The contributions of plants and other life on water quality were determined.

2.0828, LIMNOLOGY OF LAKE CHAMPLAIN
M. POTASH, Univ. of Vermont, State Resources Res. Center, *Burlington, Vermont* 05401

The objectives of the project are twofold; (1) to carry out field studies on Lake Champlain to determine, as far as possible, its physical, chemical, and biological characteristics; and (2) to continue long-term studies to determine whether these characteristics are being altered in any harmful way, or in any region of the lake, by the addition of pollutants.

Immediate research will concentrate on obtaining further descriptive information on such characteristics as temperature, light transparency, oxygen, pH, carbon dioxide, nutrients, currents and water flow, and bottom sediments. After the basic character of the lake had been described, continued research will be carried out to determine the biological character of the lake. As far as possible, research will emphasize the distribution and quantity of phytoplankton, zooplankton, benthic organisms, correlating their patterns with environmental data previously obtained.

2.0829, EVALUATION OF THE BIOLOGICAL AND PHYSICAL ENVIRONMENTAL PARAMETERS OF WATERSHEDS
S.H. KUNKLE, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Danville, Vermont* 05828 (SWC-027-ADA-4)

OBJECTIVE: Study concentrations, distributions, and migration of coliform, fecal coliform, and fecal streptococcus bacteria on a watershed; measure bacterial concentrations in streams in relation to chemical, physical, and hydrologic factors; investigate cycles of bacteria in streams, describe the migration of bacteria from watershed to stream, relate bacteria group to depth, physical characteristics, and soil moisture; and to evaluate bacteria populations in soils with reference to land use patterns.

APPROACH: Stream sampling stations will be established at several weirs along the main branch of the stream. Additional sites will be added as needed. Weekly samples will be collected from spring to autumn with additional sampling during major storm events. Soil samples from both forested and agricultural sites will be collected to evaluate concentrations and distribution of bacteria. Movement of bacteria from watershed to stream will be evaluated by plot irrigation and sampling of subsurface flows.

PROGRESS: Concentrations and cycles of two pollution-indicating bacterial groups were monitored in a small stream and on an adjacent runoff plot in Northeastern Vermont. The concentrations of these organisms in storm runoff from a partially grazed watershed rose to 50 or more times the usual non-storm values and were distinctly related to stream discharge. Total coliform concentrations in runoff from a non- grazed hay field were similar in magnitude to concentrations in the entire watershed's runoff. Results indicate that total coliform data are questionable as an indicator of pollution in rural watersheds. The fecal coliform density is a better indicator of pollution from animal waste

SUPPORTED BY U.S. Dept. of Agriculture

2.0830, RI - AN EVALUATION OF THE BOD TEST
E.M. JENNELLE, Virginia Polytechnic Institute, School of Engineering, *Blacksburg, Virginia* 24061

The research is directed towards improving one of the most serious shortcomings of any water pollution abatement program or water resource planning,i.e. a reliable means of measuring the strength of a wastewater or evaluating the efficiency of a wastewater treatment process. The biochemical oxygen demand (BOD) and the kinetics of the oxygen uptake will be evaluated and correlated with the change in total carbon, anthrone carbohydrate, protein and chemical oxygen demand.

Domestic sewage will be employed as substrate. Experiments will be conducted using sewage collected from each of the following stages of treatment. (1) raw sewage, (2) effluent from primary sedimentation, and (3) effluent from secondary sedimentation. It is proposed that the nature and composition of the organic con-

stituents of the sewage change during the treatment process, and that the biochemical oxygen demand test as it is currently employed is not a satisfactory measure of the treatment process nor is it a suitable parameter for use in establishing effluent standards.

2.0831, WATER POLLUTION
R.G. KRUTCHKOFF, Virginia Polytechnic Institute, Agricultural Experiment Sta., *Blacksburg, Virginia* 24061 (VA-0200176)

OBJECTIVE: Extend the work done on pollution in streams to estuaries.

APPROACH: Find a theoretical stochastic model for pollution in estuaries and check out the model with actual data.

PROGRESS: Work completed this year: a) A Program Extension to Pollution in Streams, b) A Stochastic Model for Biological Oxygen Demand and Dissolved Oxygen in Estuaries. Work Continuing: a) Estimating the Parameter delta For the Stochastic Model for Pollution in Streams.

SUPPORTED BY Virginia State Government

2.0832, WATER COLUMN TESTING OF FERTILIZERS
N.S. PROSSER, State Comm. of Game Inl. Fish., *Richmond, Virginia*

Water columns will be randomly paired and treated with various combinations of commercially marketed fish pond fertilizer. Elemental additives will also be applied if water analyses indicate a particular element may be present in such low quantities as to restrict primary productivity. Periodic estimates of gross photosynthesis will be made on a specificed sampling schedule during each 10 day test period. Upon initiation of each sampling period, gross photosynthesis will be measured on the 3rd, 5th, 10th and 17th days. In the beginning, 2 techniques will be employed for the measurement of gross photosynthesis; a light and dark bottle method and a diel oxygen curve method. Later on, the technique yielding the least reliable data will be eliminated.

Information will be evaluated at the end of each 10 day interval. Additives or fertilizers exhibiting little beneficial results will be discontinued in the succeeding 10 day testing period, being replaced by untested materials. Aaterials substantially increasing productivity, when opposed to controls, will again be replicated. Testing will be terminated when surface water temperatures of the lake approach a 70 degree F temperature.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0833, BOTTOM FAUNA COMPOSITION STUDIES
E.W. SURBER, State Comm. of Game Inl. Fish., *Richmond, Virginia*

Project Objective: To determine if eutrophication of the Shenandoah River is taking place, to what extent if any, and to determine if eggs, fry and young of smallmouth bass are being affected; also, to determine species of bottom fauna inhabiting the river.

Job Objective: To identify the species of bottom animals that occur in the Shenandoah River and to relate this information to available life history information.

Procedures: Many bottom fauna samples are on hand and a series of preserved specimens will be selected from the samples for the purpose of species identification. Adult and sub-imagos of mayflies will be collected at intervals throughout the year so that these stages can be associated with the nymphal forms found in the river. Certain species of Cheumatopsyche are often the most abundant caddisflies in zones of the river and rearing of these species to identifiable forms will be required. Cages will be placed in the river at convenient points. Larvae of midgeflies will be brought into the labororatory for rearing in order that identifications can be made from adult forms. Lights will be used to attract and collect insects emerging after dark at selected stations along the river. Collections will be made on a seasonal basis. Photographs of nymph, larvae and adult stages of insects will be taken using microscope attachments and camera extension tubes.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0834, A PRE-IMPOUNDMENT ECOLOGICAL STUDY OF THE BOTTOM FAUNA AND WATER QUALITY IN THE NORTH ANNA RIVER
G.M. SIMMONS, Virginia Commonwealth Univ., Graduate School, *Richmond, Virginia* 23219

This proposed research problem is directed toward evaluating the composition of bottom fauna and water quality in a river which will soon be dammed and used as a coolant for nuclear reactors. The main approach of this investigation will be to establish baselines of existing water quality (biological, chemical, and radiochemical) in order to evaluate future effects of nuclear power operation on the aquatic environment receiving the thermal effluent and possible radionuclides.

Field investigations will employ the following methods: 1. Collecting existing bottom fauna in river by qualitative and quantitative means. 2. Establishing artificial substrates, if necessary, to facilitate qualitative collecting. 3. Evaluating the physical properties of existing stream flow conditions.

Laboratory investigations would employ the following methods: 1. Rearing necessary organisms for species determination. 2. Analyses of bacteriological, chemical, and radiochemical properties of water.

The data collected from this study will be correlated with ecological data obtained after the river is impounded to assist responsible personnel in water resource management.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0835, DETECTION OF PATHOGENS IN WATER
G.J. BURNS, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Gig Harbor, Washington* 98335

Investigations of the effects of procedural variations on the efficiency of methods for the recovery of 'Salmonella', 'Shigella' and the Arizona group from water are being continued. The most promising methodology variations will be incorporated into a comparative study involving various types of natural fresh and estuarine waters.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0836, DEVELOPMENT OF METHODS FOR ISOLATION AND ENUMERATION OF VIRUS FROM WATER
W. JAKUBOWSKI, U.S. Environ. Protection Agcy., Northwestern Water Hyg. Lab., *Gig Harbor, Washington* 98335

The objective of this project is the development of methods for concentrating and enumerating human enteric viruses in drinking and recreational waters. Studies on the efficiency of poliovirus removal and recovery from water by adsorption to iron oxide, charcoal and a polyelectrolyte (PE60) will be continued. The methods in use will be scaled up to process tap and estuarine water volumes on the order of 50 to 100 gallons. Virus multiplicities to be tested will be at least as low as 1 PFU/gallon. Optimum conditions of adsorbent load, filtration pressure and flow rate will be investigated. Further studies will be conducted on factors affecting elution of adsorbed virus.

Continuous flow centrifugation will be examined as a method for concentration of viruses from turbid waters. Kaolin, bentonite and precipitated aluminum hydroxide will be added to water samples of up to 10 gal. and compared for efficiency of virus removal and recovery. The effects of centrifugation speed, flow rates and adsorbent concentration will be determined.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

2.0837, DETECTION AND SIGNIFICANCE OF KLEBSIELLA IN WATER
G.J. VASCONCELOS, U.S. Environ. Protection Agcy., Northwestern Water Hyg. Lab., *Gig Harbor, Washington* 98335

The objective of this project is to determine whether high numbers of Klebsiella in water competitively suppress the growth of recognized coliform indicator groups during enumeration by the membrane filter method. Since coliforms are often used assessing the bacterial quality of recreational and potable waters,

the inhibitory influence of so- called nuisance organisms must be considered in the final sanitary evaluation of any body of water. Methodology will be established for the quantitative differentiation of Klebsiella from coliform and other related Enterobacteriaceae. Differentiation will be accomplished by observation of morphological features and reactions on various biochemical media designed to elucidate specific phenotypic characteristics. Once methodology has been established, the recovery rates of low densities of coliform (Escherichia coli and Aerobacter aerogenes) from water containing high concentrations of Klebsiella (10 to the 4th power or more) will be compared with samples containing similar numbers of coliforms but no Klebsiella. The study will involve both fresh and estuarine waters. Comparisons will be made of numbers of coliforms recovered versus number of Klebsiella present. Studies will include field investigations of waters where high levels of Klebsiella are thought to be present.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

2.0838, TESTS OF EFFICIENCY OF CHANGES IN FILTER DESIGN AND FILTER MEDIA
R.E. BURROWS, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Longview, Washington* 98632

Objective: To test efficacy of upflow filter as compared to the conventional downflow biological filter and artificial media as compared to sharp rock for the removal of ammonia in reuse systems.

Procedure: To test both the upflow filter and artificial media, a 20-foot, circular, fish rearing tank will be assembled, 2-4x20 upflow filters constructed, and pumps, piping, and aeration tank installed. One filter will have 320 cu. ft. of Koroseal plus 80 cu. ft. of oyster shell to provide 11,840 sq. ft. of area in the Koroseal. The second filter will have 320 cu. ft. of fiber glass and 80 cu. ft. of oyster shell to provide 25,280 sq. ft. of area in the fiber glass. The flow through both filters will be 300 gpm or slightly less than 2 gpm. per square foot of area. Supplemental water will be added to the circulating flow at the rate of 10 percent. Tests will be conducted under conditions with normal fish loads to determine if the area per cubic foot of artificial media is a factor in denitrification. If the fiber glass filter does not prove to be more efficient than the Koroseal it will be dismantled and sharp rock substituted. During operation, chemical tests will be conducted to determine the quality of both the overflow and backwash water for comparison with the conventional reuse system.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0839, DEVELOPMENT OF AN IN SITU MARINE BIOASSAY WITH CLAMS
C.E. WOELKE, State Dept. of Fisheries, *Olympia, Washington* 98501

The basic objective of this study is to develop a bioassay of Pacific Coast estuarine water with embryos of indigenous species of clams and demonstrate its use to detect, monitor, and biologically quantify the effects of pollutants in the natural environment.

To achieve this goal the seasonal reproductive cycles of seven major species of clams, as determined from histological examination of adult clam gonads, will be related to those environmental factors which might be expected to affect their spawning. The results of this phase of the study will be employed in developing techniques for controlling gonadal maturation and spawning of as many species of clams as possible. Fertilized embryos from controlled spawnings will then be used to bioassay known toxicants and marine water samples under controlled laboratory conditions.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0840, CORRELATED STUDIES OF VANCOUVER LAKE--WATER QUALITY PREDICTION STUDY
S.K. BHAGAT, Washington State University, School of Engineering, *Pullman, Washington* 99163

Vancouver Lake, Washington, in its present state is shallow and polluted but it has the potential of becoming a valuable water resource. The lake is connected with the Columbia River on its north end and it is the only water access to the lake. There are plans to dredge the lake to a depth of 10-15 feet as well as connect the lake on its south end with the Columbia River.

The primary object of this study is to predict the effect of the planned changes on the water quality of the lake and to see if the usefulness of the lake can be improved by these changes.

The plan of operation includes determination of the existing water quality of both the Columbia River and the Vancouver Lake; predictions of obtainable water quality in the lake based on the considerations of channeled flow from the Columbia River, changes in the lake depth, improvements in present pollutional loadings and the removal of organics and nutrients in present bottom sediments. Residence times and flow patterns will be obtained from the hydraulic model study being conducted by the Albrook Hydraulic Laboratory of this university.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0841, THE PREDICTION OF WATER QUALITY ASPECTS OF THE WENATCHEE RIVER
H.D. COPP, Washington State University, School of Engineering, *Pullman, Washington* 99163

A pumped-storage hydroelectric power development has been proposed by the Sponsor on the Wenatchee River, a mountain stream in north central Washington State. Since this river is an important fish spawning stream, tributary to the Columbia River, and since recreation activity is increasing in the watershed, influences of the proposed power project on existing water quality need to be predicted.

Simulation techniques by digital computer are being developed for prediction purposes. Weather phenomena, system hydrology, heat transfer, principles and mixing processes have been programmed for both reservoir and stream waters to compute temperatures and oxygen and nitrogen contents in these waters. A program is operable and is quite general, i.e., it is not tied to the system under consideration. At present, July 1967, program optimization, process simulation mechanics, and logic continuity are under critical review.

SUPPORTED BY Chelan County Government - Washington

2.0842, ADVANCE WARNING OF GROUND-WATER POLLUTION HAZARDS, WITH SPECIAL REFERENCE TO AQUIFERS IN GLACIAL OUTWASH
J.W. CROSBY, Washington State University, State Water Research Center, *Pullman, Washington* 99163

It is proposed to study methods of providing advance warnings of pollution build-up so that public health hazards can be avoided. The research is to be done on the Spokane Valley aquifer where conditions now exist which are conducive to contamination of the Spokane water supply. Geoelectrical methods, utilizing both standard and specially designed probes, will be investigated and comparison drawn between electrical properties of the groundwater and water quality analyses. The desirable end result of the project would be to establish rapid, routine methods of identifying polluted zones in stratified groundwaters.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0843, SURVIVAL OF INTESTINAL BACTERIA IN PRISTINE WATERS
D.L. JOHNSTONE, Washington State University, School of Engineering, *Pullman, Washington* 99163

A comparison of regrowth and die-off rates of pathogenic and non- pathogenic bacteria of intestinal origin will be studied in pristine waters. The recreation potential of our pristine waters are being developed to their fullest. With this increase in pressure on these types of waters the possibility of fecal contamination is a very real threat. However, there is no data available on the comparative survival of intestinal bacteria in high quality waters. Without such comparison we can determine the necessary degree of treatment of wastes nor the health hazard associated with pristine waters even though they may be routinely tested for coliforms.

2. WATER QUALITY

Samples will be collected from pristine streams, only recently accessible, over a period of two years to encompass the annual water cycle. Initially the samples will be characterized bacteriologically and chemically. After the initial profile is established, samples will be either filtered or used raw and innoculated with known numbers of the organism to be tested. Kinetics of survival will be ascertained under aerated and static conditions at selected low temperatures over extended time periods.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0844, GEOCHEMICAL OCEAN SECTION STUDY

R.W. PERKINS, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

GEOSECS is designed to perform a systematic world survey of the chemical and radiochemical components of the ocean. Where appropriate and practical, measurements of these components in the overlying air and underlying sediments will be included. This investigation includes trace element studies, natural and artificial radionuclide measurements, and a Be-7 air to sea exchange study. Trace element measurements for 10 to 12 ocean water constituents can be made by direct counting of neutron activated seawater. Samples collected on each of the depth profile samples will be analyzed for this element group. An additional group of some 20 elements requires group or specific separations and will be measured on selected depth profiles. Some 15 to 20 natural and artificial radionuclides will be measured on the various depth profiles. It is planned that the natural radionuclides U-238, Th-234, Ra-228, Ra- 226, Pb-210, and Be-7 will be measured. Concentrations of the airborne radionuclides will be monitored continuously during the sampling program to provide a basis for defining the rate of air to sea transfer. Surface layers of the ocean bottom sediments will be obtained at each collection site to permit an estimate of the sedimentation rates from the overlying water columns.

Results: Seawater samples collected during a pre-GEOSECS testing cruise at 16 depths between the surface and 4000 meters in 30-liter modified Niskin bottles were analyzed for their trace element content. The samples are providing information needed to determine the optimum sampling and storage methods to be used. Analysis consists of neutron activation and direct gamma-ray spectrometry utilizing multidimensional and GE (Li) analyzers. Preliminary analysis of the seawater samples indicates that the method of storing the samples is a critical factor.

2.0845, TESTING METHODS FOR EVALUATION OF BOTH EFFECTIVENESS AND TOXICITY TO AQUATIC LIFE OF VARIOUS TREATING MATERIALS

P.C. WALKUP, Battelle Memorial Institute, *Richland, Washington* 99352

Current methods for evaluating the effectiveness and toxicity of oil spill treating agents (dispersants, sorbents, burning agents, biological degrading agents, sinking agents, and beach cleaners) were evaluated. No method of effectiveness testing is totally applicable. Recommended tests were based on refinement and development of procedures given in MIL-S-22864A (Ships). Methods of toxicity determination, with the exception of BOD measurement, are generally adequate. However, shortcut methods of measurement of sublethal toxicity, better selection of test organisms, and correlation between laboratory and field observations are needed.

SUPPORTED BY Amer. Petroleum Institute

2.0846, RELATION OF RIVER-RUN IMPOUNDMENTS TO SALMON PRODUCTION

A.J. NOVOTNY, U.S. Dept. of Commerce, Natl. Marine Fisheries Service, *Seattle, Washington* 98102

This program seeks to develop a self-sustained, mobile field laboratory, designed for maximum flexibility, which will provide a working base for unlimited aquatic environmental studies in navigable impoundments, and eventually in marine bays and estuaries. Primary emphasis is being placed on studies related to changes in the environment induced directly or indirectly by human activities and the effects of these environmental changes on salmon. These studies will include on-site experimental control of water quality to determine the feasibility of 'carrying' salmon through critical phases of their life cycle in river-run impoundments. Parameters of control include temperature, filtration, sterilization, dissolved gases, and waste products.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0847, ORGANIC-MATTER BUDGET FOR PUGET SOUND

K. BANSE, Univ. of Washington, School of Arts, *Seattle, Washington* 98105

Decisions on multiple use of the nearshore environment should be based, as nearly as possible, on the evaluation of quantifiable alternatives. Decisions on uses that affect the biota would benefit greatly from a numerical understanding of the major pathways of organic matter, be it alive or dead, and the rates of change in the water and on the bottom. This year, it will be most advantageous to apply existing analytical models of plankton production of the Steele-Riley approach to the very large body of phytoplankton data in hand, in order to sort the material and learn whether the existing information on parts of Puget Sound can be used for checking a larger model. This will thereby tie together data on hydrography and water exchange, nutrient concentrations and primary productivity. By the latter part of the year a consideration of the zooplankton and the losses of organic matter to, and regeneration of nutrient salts by, the seabed will begin. Biomass data from two time series stations will be used for the zooplankton. Further, a current sampling program will also include larger pelagic organisms like euphausiid shrimps and small fishes which are mostly links in the food chain to large fishes. Information should be available at that time on the distribution of communities, including the biomass. The same information on species occurrence and abundance will be usable for studies of flatfish food and as indicators for long-term pollution effects away from the shore.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0848, LAKE NUTRIENT STUDY

W.T. EDMONDSON, Univ. of Washington, Graduate School, *Seattle, Washington* 98105

For a long time, Lake Washington received increasing amounts of treated sewage, and responded rather promptly to each major change. As late as 1950, it could still be regarded as relatively unproductive, and certainly was not producing nuisance conditions. By 1955 it was unmistakably deteriorating; it was clear that Lake Washington, like many before it, was showing increased productivity as a result of enrichment with nutrient-rich sewage effluent. In 1958 a major sewage revision was decided by public vote. Diversion started in 1963 and was completed in 1968. The lake has responded promptly and sensitively to the progressive decrease in nutrition with reduced production of algae and many other changes related to the change in productivity.

The sediments show a record of the changing productive status of the lake both in the chemical composition and the content of microfossils.

Thus Lake Washington has been an extremely suitable object for a study of the relation between nutrient income and population productivity and abundance. In addition to the scientific value of the limnological study, the results have been useful locally in making decisions about how to handle the pollution problem, and are beneficial in helping to understand eutrophication in general. Research will be continued on Lake Washington as it reverts to a less productive condition.

SUPPORTED BY U.S. National Science Foundation

2.0849, GEOSECS - C14 FACILITY AND ANALYSIS OF OCEAN WATER SAMPLES

M. STUIVER, Univ. of Washington, Graduate School, *Seattle, Washington* 98105

Considering the ocean as a source of food, a disposal area for nuclear and industrial waste products, and a controlling factor in the earth's climatic regime, our ultimate use of the sea is critically dependent on a detailed understanding of processes presently understood in only the vaguest and most qualitative way. These are the stirring and mixing processes in the deep sea, the interchange of material between deep and surface water, the variation of organic productivity throughout the ocean and the exchange of water and gases with the atmosphere. The GEOSECS program will measure in detail the oceanic constituents along Arctic to Antarctic sections at all depths, to provide, for the first time, a set of physical and chemical parameters measured on the same water samples. These data will provide the input for quantitative studies of oceanic mixing and organic productivity, and, at the same time, serve as a base-line for the levels of pollutants and of fission and waste products being added to the sea. Stuiver will concentrate on C14. If measurements are made with higher precision than currently available, C14 holds the greatest wealth of information as the most important oceanic radio tracer because it is involved in both the inorganic-organic carbon cycle and the general circulation problem. The investment in electronics, shielding, counters, and vacuum equipment is justified by the need for a large number of highly precise (plus or minus 4 per mil) and reliable results.

2.0850, BIOLOGICAL STREAM SURVEILLANCE
R. MENENDEZ, State Div. of Wildlife Resour., *Charleston, West Virginia* 25305

Objectives: To establish a biological surveillance network on selected high quality streams to determine present biological conditions and to monitor any changes resulting from new industrial activities.

Procedures: Benthic samples will be collected quarterly from selected high quality streams on which new industrial activities are planned. Sampling stations will be strategically located so as to effectively monitor any stream changes and will include stations above, below, and at the point of origin of the new industrial activity. Samples will be collected with a Surber square foot sampler and with an artificial substrate sampler. A minimum of three samples will be collected from each station at various points across the stream. The artificial substrate samplers, as described by Hester and Dendy (1962), will be anchored to the stream bottom at the various stations and serviced quarterly. When collecting samples, the sampler will be enclosed in a small plastic bag before removal from the water to prevent loss of organisms. Samplers will be transported to the laboratory in this manner where they can be dismantled and all organisms removed and preserved for identification. A sufficient supply of samplers will be maintained so that when one is removed from the stream, another can be returned in its place.

All organisms will be identified to genus and species when possible and classed as to their tolerance to pollution. Use will be made of all pertinent literature to aid in determining tolerance levels.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0851, IDENTIFICATION AND CONTROL OF PETROCHEMICAL POLLUTANTS INHIBITORY TO ANAEROBIC TREATMENT
R.A. CONWAY, Union Carbide Corporation, *Charleston, West Virginia* 25303

This eighteen-month investigation will serve to complement the earlier FWPCA Grant, 12020-DIS, 'Anaerobic Treatment of Synthetic Organic Wastes,' by identifying chemicals common to many petrochemical wastes which are inhibitory to anaerobic biological treatment.

The initial phase will involve the identification of chemicals and the levels of these chemicals which are acutely inhibitory to anaerobic biodegradation processes, while subsequent studies will deal with the control of the toxicity of these materials through acclimation and through dilution techniques. Emphasis will be placed on alpha-beta- unsaturated carbonyl compounds, sulfates, and aromatic structures. Parameters such as gas production and organic carbon reduction will be used to determine the effect of the chemical on the anaerobic test system.

A second phase of the project will include the study and use of an anaerobic photosynthetic bacterial-algal culture to control sulfide toxicity in a lagoon-type system. These tests will be conducted in twin units under a variety of operating conditions while monitoring gas production, organic carbon reduction and sulfur balances.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0852, CHEMICAL CHARACTERISTICS OF WATERS IN FLOODED BITUMINOUS-COAL MINESHAFTS
R.G. CORBETT, West Va. University, Water Research Institute, *Morgantown, West Virginia* 26506

We shall determine quantitatively the major chemical components of waters from various levels in flooded bituminous-coal mineshafts. We shall attempt to measure Eh and pH of samples without altering the values in the process of sampling. These data may aid in better understanding the mechanism of pyrite alteration in the mine environment.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0853, NUTRITIONAL ECOLOGY AND COMMUNITY STRUCTURE OF THE PHYTOPLANKTON OF GREEN BAY
P.F. SAGER, Univ. of Wisconsin, Graduate School, *Green Bay, Wisconsin* 54302

The proposed research involves investigations on the relationship between phytoplankton community structure and nutrient availability. Previous studies have indicated an inverse relationship between species diversity and nutrient availability in the water. In this study, equal emphasis will be placed on the algal cell content of the important plant nutrients, nitrogen and phosphorous. Techniques to be utilized will determine the limiting or non-limiting nature of these nutrients in the algal material itself. The question to be answered is how is nutrient availability reflected in the structure of the community.

The phytoplankton community existing along the nutrient gradients in the bay resulting from pollution inputs provides a large experimental system in which this question can be explored. At selected sampling stations, seasonal estimates of community structure will be made from species-abundance enumerations and the subsequent calculation of a species diversity index. Pigment extraction will also be utilized for the estimation of community structure and standing crop. Several physico-chemical variables will be measured concurrently. The data will be examined in a framework which will lead to a better understanding of the factors that regulate structure and metabolism in the phytoplankton community in the face of an ecological disturbance (water pollution).

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0854, WATER QUALITY MONITORING STUDIES
J.W. MASON, State Dept. of Nat. Resources, *Madison, Wisconsin* 53701

A statewide program is under way to detect and document changes in water quality which may occur in various lakes and streams as a result of changing use patterns (shoreline development, recreational development, dam construction, dredging, ditching, irrigation, etc.). In the waters selected for monitoring, the following parameters are measured four times yearly: temperature and oxygen profiles, pH, alkalinity, water clarity, resistivity, nutrient concentrations, and other elements. Biota changes, if any, are noted (fish populations, vegetation, etc.). Streams are also being monitored for any chemical changes that may occur, and in addition continuous temperature recordings are being made. In situations where fish populations are suspected to be affected by development they are studied intensively (dam constructing, ditching, irrigation, land cover changes). Lakes and streams which man-made changes are not expected to affect are being monitored as 'bench mark' waters.

SUPPORTED BY Wisconsin State Government - Madison

2.0855, A COMPARISON OF TOTAL COLIFORM AND FECAL COLIFORM COUNTS IN STREAM POLLUTION SURVEYS

D.H. SCHUETTPELZ, State Div. of Env. Protection, *Madison, Wisconsin* 53701

The study consists of a literature review and limited field sampling to determine if the fecal coliform, rather than the total coliform count, would be a better indicator of bacterial contamination of surface waters. This study will determine whether the fecal coliform organism will be used in routine stream pollution surveys conducted by the sponsoring department. The field sampling is being conducted below a sewage treatment plant and will provide die-off rates and correlation of the coliform strains in the stream.

All bacterial counts are performed by the membrane filter technique and are accepted as being representative (equivalent to MPN) of the true fecal and total coliform populations. Analyses are performed in accordance with Standard Methods for the Examination of Water and Wastewater (12th ed.) at the Wisconsin State Laboratory of Hygiene.

SUPPORTED BY Wisconsin State Government - Madison

2.0856, WATER REOURCES OF SOUTHEASTERN WISCONSIN - RACINE AND KENOSHA COUNTIES

R.D. HUTCHINSON, U.S. Dept. of the Interior, Geological Survey, *Madison, Wisconsin* 53706

This research is part of the program of water resources investigation conducted by the U. S. Geological Survey in cooperation with the State of Wisconsin.

Purpose - To determine the quantity and quality of the ground water resources available for the expanding population and increasing industrialization in southeastern Wisconsin.

Methods - Daily and periodic water-level measurements will be made to supplement current records and gages to record pumpage will be installed on selected wells. Hydrographs of wells will be used to determine the effects of recharge and discharge. Areas of recharge and discharge and the direction of groundwater movement will be determined. Quality of water data will be correlated with geologic information to map the geographic and stratigraphic distribution of chemical constituents that occur in critical quantities.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0857, APPLICATION OF REMOTE SENSING TO THE DETERMINATION OF WATER QUALITY

M.S. ADAMS, Univ. of Wisconsin, Inst. of Environmental Studies, *Madison, Wisconsin* 53706

Abstract: This research is directed towards the establishment of correlations between aerial remote sensing responses and water pollution parameters. Once established, these correlations would be a valuable tool in both the enforcement of water pollution legislation and in the overall planning of a given watershed. A study of the spectral reflectance and radiant emission properties, as measured in the laboratory using Gamma Scientific and Isco Spectro-radiometers, will be conducted for samples containing known chemical, physical and biological characteristics. The reflectance and emission properties will be correlated with specific water pollutants and the relative magnitude of these radiant emission properties of water will be conducted in situ through radiometric measurements. The correlation between these two properties in specific water pollutants and secondary pollutional indicators will be established. Based on both laboratory and field measurements, aerial remote sensing responses will be interpreted and appropriate wavelengths and/or wavelength combinations will be established for specific pollutional parameters. In coordination with Wisconsin state agencies, spectral bands will be prescribed, and data handling and analysis techniques will be developed so that the research findings can be used as a practical tool for water pollution control.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

2.0858, INSECTICIDE ADSORPTION BY LAKE SEDIMENTS AS A FACTOR CONTROLLING INSECTICIDE ACCUMULATION IN LAKES

G. CHESTERS, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

Detailed Objectives: a. To determine the extent of adsorption of certain insecticides by intact and fractionated lake sediments and the bonding mechanisms involved. b. To relate adsorption to a characterization and classification of lake sediments. c. To ascertain the effect of adsorption on chemical and biochemical degradability.

The extent of insecticide adsorption will be evaluated by equilibration and chromatographic techniques utilizing gas chromatographic and radioisotopic methods for insecticide determination. Properties of the insecticides and the sediments controlling the extent of adsorption will be ascertained. The effect of adsorption on the chemical and biochemical degradability will be determined by comparison of degradation rates in the presence and absence of adsorbents. Properties of sediments will also be related to their origin, environment of deposition and location to obtain a classification useful for prediction of the extent of insecticide accumulation in lakes.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0859, TISSUE ANALYSIS FOR NUTRIENT ASSAY OF NATURAL WATERS

G.C. GERLOFF, Univ. of Wisconsin, School of Letters, *Madison, Wisconsin* 53706

The primary goals of this project are: (1) To develop the tissue analysis technique as a simple and reliable procedure for evaluating the adequacy of nutrient supplies in lakes and streams for the growth of nuisance producing angiosperm aquatic plants (macrophytes). This includes determining if the supply of any essential mineral element becomes limiting for the growth of the aquatic plants during the summer months in representative Wisconsin lakes. (2) To establish procedures for the successful culture of angiosperm aquatic plants in synthetic nutrient media and to study in detail the nutritional requirements of several of the most troublesome species. Nutritional factors which might be of specific importance in explaining the distribution and abundance of the plants under field conditions will be of particular interest.

The tissue analysis technique and the information gained on this project should be very useful in programs being developed by sanitary engineers and chemists to reduce nuisance plant growths by removal of growth-limiting essential mineral elements from pollution sources.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0860, ARTIFICIAL SUBSTRATE SAMPLERS AS INDICATORS OF WATER QUALITY

W.L. HILSENHOFF, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

The effectiveness and limitations of an artificial substrate sampler under a variety of conditions will be statistically evaluated. Replicated tests will be conducted to determine the rate of colonization at different temperatures, the effect of periphyton on the rate of colonization, the relationship of current velocity to debris accumulation and the rate and degree of colonization, the suitability of various substrates for use in samplers, and the effect of the height of the sampler above the stream bottom, its position in the stream, shade and sunlight, and surrounding substrate on the degree and type of colonization.

The effectiveness of different types of artificial substrate samplers will be compared, and the efficiency of removing insects by agitation will be evaluated. Samplers will be placed above, below and far downstream from known sources of various types of pollution to demonstrate the ability of samplers to detect pollution and the role of various species of insects as indicator organisms.

This project was initiated in June 1968 and will be completed in January 1971.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0861, APPLICATION OF REMOTE SENSING TO THE DETERMINATION OF MIXING ZONE FOR WASTE EFFLUENTS DISCHARGED INTO STREAMS OR RIVERS
J.A. HOOPES, Univ. of Wisconsin, Inst. of Environmental Studies, *Madison, Wisconsin* 53706

Abstract: The basic objective of this project is to develop a relationship for the extent of the mixing zone in terms of the characteristics of the outfall, effluent, and water body. Using this definition of a mixing zone, government agencies could establish a reasonable sampling and regulation program for waste effluent discharges. Through an extensive literature search a working hypothesis for the extent of the mixing zone as a function of outfall, effluent and water body characteristics has been developed. This literature search will be continued and expanded to include additional laboratory and field studies. Using laboratory flumes and tanks to simulate 'idealized' river and lake environments, rates of dilution or mixing of tracers will be measured. Mathematical models will be developed along the lines of the classical jet and plume analysis subject to the constraints of the type and location of the outfall and the environment. Intensive aerial remote sensing, coupled with detailed ground measurements of waste effluent concentration distribution temperatures and velocities will be undertaken along the lower Fox River, the western shoreline of Lake Michigan, the Madison lakes, and the Wisconsin River (Wausau to Pentwell Reservoir). The observed 'mixing zones' will be compared to the predicted ones using the functional relation developed.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

2.0862, TOXIC ELEMENT CONTAMINATION OF WATERS AND RELATED ENVIRONMENT
D.R. KEENEY, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

The ultimate objective is to evaluate the current magnitude and future hazards of contamination of water and food by Be, Cd, Ni and As.

Detailed objectives are 1) to elucidate the amounts and forms of Be, Cd, Ni and As in soils, plants and surface waters from direct addition from industrial wastes, the atmosphere, and other man-derived sources, and 2) to evaluate the uptake of Be, Cd, Ni and As by plants and the transport of these elements through soils into groundwater.

The extent of contamination of water and related environments by Be, Cd, Ni and As in dustfall, precipitation, soils, waters and lake and river sediments at locations varying in population density and industrial activity will be elucidated. The conditions affecting the rate and extent of Be, Cd, Ni and As uptake by plants, and the critical factors governing the entry of these elements into water and food supplies will be evaluted. The ultimate aim of the investigation is to provide information needed to evaluate present and future deleterious effects of Be, Cd, Ni and As on water and related environments.

2.0863, GEO-ENVIRONMENTAL AND MINERAL RESOURCES PROGRAM
R.A. RAGOTZKIE, Univ. of Wisconsin, School of Letters, *Madison, Wisconsin* 53706

Research in minerals will concentrate on three major areas of investigation: Green Bay Manganese, Marine Mineral Placers, and Minerals Law.

The Manganese investigation will consider two main aspects: inshore acoustic profiling and charting of pollutant muds and analysis and charting of manganese and other elements, including possible pollutant sources. The prime objective is to determine the mode of origin and distribution of the pellets and use such information as a guide for further exploration of the Great Lakes and elsewhere.

Marine Mineral Placer investigations will consist of field and laboratory studies of heavy mineral dispersal origin and the limits of marine placers. The major objective is to establish exploration guides for locating placers of economic value.

To provide guidance for program investigators as well as industry, information on permits and exploration rules also will be assembled. Present laws and regulations covering marine and Great Lakes mining will be included in the collection.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0864, APPLICATION OF REMOTE SENSING TO SURFACE PARAMETERS OF LARGE WATER BODIES
R.A. RAGOTZKIE, Univ. of Wisconsin, Inst. of Environmental Studies, *Madison, Wisconsin* 53706

Abstract: This research is centered around the detection and monitoring of oil and thermal pollution as well as the determination of near-shore circulation patterns. An attempt is being made to find a remote sensor which will suitably detect an oil slick from an aircraft or satellite platform. Current research dictates that instruments operating in the UV or microwave portions of the spectrum will be useful. The spectral responses of oil samples in the visible spectrum will be determined with a spectrophotometer. This will reveal any possibility of utilizing a particular film filter combination or show a need for a UV scanner. A literature search will be made to determine the possibility of using an instrument operating in the microwave region. Infrared radiometers will be used initially to monitor thermal plumes from nuclear power plant discharges, with infrared scanners being used later. Seasonal changes in the thermal structure of the receiving water will be investigated. Airborne infrared radiometry will be used for the detection and monitoring of near-shore circulation patterns because these patterns are associated with substantial horizontal temperature gradients, normal to the direction of flow.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

2.0865, EVALUATION OF THE PROVISIONAL ALGAL ASSAY PROCEDURE
G.A. ROHLICH, Univ. of Wisconsin, Water Resources Center, *Madison, Wisconsin*

This project consists of a laboratory evaluation of two bioassay techniques, batch and continuous culture, for investigating algal growth-nutrient concentration relationships in natural and enriched waters. The project is part of a cooperative effort sponsored by the Joint Industry/Government Task Force on Eutrophication to develop a reliable and reproducible assay procedure which can be employed universally.

2.0866, APPLICATION OF REMOTE SENSING TO HYDROGEOLOGY
D.A. STEPHENSON, Univ. of Wisconsin, School of Natural Sciences, *Madison, Wisconsin* 53706

Abstract: The purpose of this research is to investigate the application of remote sensing to: a) define ground water influx points to surface water bodies; b) determine patterns of distribution for pollutants entering surface water bodies; c) establish lateral and/or abnormal temperature gradients within soils associated with ground water flow systems; and d) determine patterns of pollutant distribution within shallow ground water flow systems. All of the above are currently under investigation using conventional ground based techniques. The sites currently under investigation are: a) City of Madison Truax Field Sanitary Landfill Site; b) City of Madison Dane County Coliseum Sanitary Landfill Site, and c) Sulfite Liquor Disposal at the Badger Paper Company, Peshtigo, Wisconsin. During the first phase of this study, appropriate portions of the reflectance and emission spectrum would be imaged and coordinated with simultaneous ground truth. The second phase of the study will consist of qualifying the remote sensed imagery with available ground truth. The third phase will consist of applying the qualified remote sensed imagery to the investigation of the ground water flow system. The application of remote sensing to these investigations would provide

meaningful data for basin-wide water resource planning, pollution migration control, and ground water-surface water relationship studies.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

2.0867, ATOMIC ABSORPTION ANALYSIS OF PHOSPHATES IN WATER
C.O. HUBER, Univ. of Wisconsin, Graduate School, *Milwaukee, Wisconsin*

The initial aim is to determine phosphate in natural and waste waters by atomic absorption with high sensitivity, speed and specificity. The linear absorbance decrease for metals due to flame compound formation will be observed quantitatively. The investigation will necessarily include studies of flame reaction stoichiometries and rates and should provide improved understanding of compound formation in flames. This will be used to establish a specific determination for the various phosphates as well as for other non metallic anions. The extension of the advantages of atomic absorption to analysis of many anions at concentrations present in natural waters is the final objective.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr Qua. Adm.

2.0868, ECOLOGICAL STUDIES OF THE SURFACE WATERS OF THE WHITEWATER CREEK WATERSHED, WALWORTH, ROCK, AND JEFFERSON COUNTIES, WISCONSIN
S.G. SMITH, Univ. of Wisconsin, Graduate School, *Whitewater, Wisconsin* 53190

Distribution and relative abundance of selected plants and animals will be correlated with physical and chemical features of the surface waters of the Whitewater Creek watershed. Although primary emphasis will be placed on the streams, preliminary studies will be made of the lakes which have been formed by the damming of the streams. Detailed studies will be primarily concerned with vascular plants, fishes and selected algae. Although the primary objective of the project is to initiate a long-range interdisciplinary research program, certain specific problems will also be investigated, i.e. 1) the movements of selected species of fish within the stream system, and 2) the genecology of hybridizing or otherwise genetically variable populations of the round-stemmed bulrushes (Scirpus spp.) and possibly Potamogeton in relation to habitat disturbance and other ecological factors. Organisms studied will be evaluated as to their usefulness as indicators of water quality and other environmental conditions.

2.0869, AERATION OF LAGOONS IN RIGOROUS CLIMATE AREAS
R.L. CHAMPLIN, Univ. of Wyoming, School of Engineering, *Laramie, Wyoming* 82070

Demonstration Grant: Two Parts. Part I. A water balance for the City of Laramie, Wyoming is being measured. This includes measuring all incoming flow (municipal, surface and ground water) and all outgoing flow (storm drainage, sewage flow, ground water and streams). Part II. Aeration of a pilot lagoon is being investigated. Due to the rigorous climate, treatment of sewage by the lagoon system is inadequate during much of the year. The parameters being investigated are: amount of air, loading and detention time, and temperature effects. The effect of present treatment on the Laramie River is being monitored.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

C. WATER TREATMENT

Physical Management Or Treatment Applied to Poor Quality Water Before Utilization. Includes Chlorination for Potable Water and Related Sanitation Measures.

2.0870, TREATMENT OF WATER-PLANT SLUDGES
J.F. JUDKINS, Auburn University, School of Engineering, *Auburn, Alabama* 36830

The objectives of the proposed research are to investigate the crystal seeding process as a means of improving the filterability of water treatment plant sludge. The process will be investigated for its applicability to both coagulant sludges and lime-softening sludges. Variables of interest will include crystal seed dosage, mixing rate and the concentrations of impurities in the water. Studies will be conducted on laboratory samples prepared by the addition of typical concentrations of turbidity, hardness and alkalinity to distilled water.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0871, THE EFFECTIVENESS OF CONTACT FILTER FOR THE REMOVAL OF IRON FROM GROUND WATER
W. KIM, Univ. of Alaska, Inst. of Water Resources, *College, Alaska* 99735

The objective of the proposed study is to explore the applicability of the contact filter in the removal of iron from ground water. A contact filter process developed by Minz in Russia consists of a deep sand bed (six feet) through which the coagulated suspension is passed in upward direction. Theoretically this process should perform better than conventional sand filters due to the decreasing grain size of filter media in the direction of flow, and due to the greater depth effective in the filtration. Iron removal from ground water requires the oxidation of ferrous iron, and flocculation and separation of ferric precipitate. The contact filter may promote not only flocculation and separation steps but also the oxidation of ferric ion due to the intimate contact of iron-coated filter media with the incoming water.

The relative effectiveness of the contact filter and conventional sand filters and the optimum media characteristics will be determined by running pilot filter tests under controlled conditions.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0872, WATER PURIFICATION BY LARGE-SCALE ELECTROPHORESIS
M. BIER, U.S. Veterans Administration, Hospital, *Tucson, Arizona* 85713

In prior years, this work has been always fully supported by extramural grants. Because of lack of current support, no experimental work has been carried on in the past year. It is the intent of the principal investigator to seek new support to reactivate this project.

Nevertheless, there remains widespread interest in the principal investigator's prior work in this field. For instance, he was invited a. to present a paper on Water Treatment by Electrophoresis at the Annual Meeting of the Institute of Electrical and Electronics Engineers, Detroit, Mich., October 12-16, 1969. This paper had to be read by title only as travel funds were not made available. b. to organize a Symposium on Membrane Processes for Industry and Biomedicine, for the American Chemical Society. The Symposium was be held at the Annual Meeting in Chicago, Sept. 1970, and the Proceedings were published by Plenum Press, in early 1971. His own contribution is entitled Electrokinetic Membrane Processes. c. to participate in the Symposium on Recent Advances in Separation Techniques, at the Annual Meeting of the AmericanInstitute of Chemical Engineers, Houston, Spring 1971. The paper, entitled: Electrophoresis as an Industrial Process will be included in the Symposium Proceedings.

SUPPORTED BY U.S. Veterans Administration

2.0873, INVESTIGATION INTO THE POSSIBLE AGRICULTURAL USE OF RECONDITIONED WATER FROM THE PROPOSED SOUTH-EASTERN PURIFICATION PLANT
A.W. BIRD, Victoria Rivers & Water Comm., *Armadale, Victoria, Australia*

Part of a project investigating possibility of using water from Purification Plant for agricultural and other purposes.

General investigations proceeding, pilot field tests completed.

SUPPORTED BY Australian National University

2.0874, FLOC STRENGTH AND FILTERABILITY OF PRE-TREATED WATER
H.F. LUDWIG, Ludwig Engin. & Sci. Res., *Arcadia, California* 91006

This study is primarily concerned with the effect of floc characteristics on the performance of rapid sand filters. Floc strength is to be investigated as a measure of floc characteristics. Floc strength will be measured by the degree of floc breakdown after being exposed to a velocity gradient producing shear stress.

The filterability of pretreated water is to be measured by the Silting Index utilizing a membrane filter, by Boucher's Index, and by floc retention capacity of a rapid sand filter.

The effect of pH, alum dosage, coagulant aids, mixing conditions, and lime addition on floc strength will be investigated; their effects on filter performance, expressed by filterability indices, will be studied in pilot plant operation.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0875, ORTHOKINETIC FLOCCULATION OF HETERODISPERSED SYSTEMS
W.J. KAUFMAN, Univ. of California, School of Engineering, *Berkeley, California* 94720

The broad aim of the proposed research continues to be the elucidation of the relationships of the rate of orthokinetic flocculation to the hydrodynamic parameters describing turbulence in stirred reactors. In the present proposal, theoretical formulae are presented that relate the rate of flocculation to the rate of energy dissipation and the turbulence spectrum, and the rate of deflocculation, or breakup, to similar turbulence parameters and floc strength. It is expected that the establishment of these relationships will lead to the more rational design and operation of the flocculation and precipitation systems employed in water and waste treatment. The principal aim of the proposed research will be to validate these expressions experimentally or to modify them as appropriate to describe the flocculation process under steady-state conditions in stirred reactors. Recognizing that improved flocculator performance may accompany increased rates of energy dissipation only if the flocs are sufficiently strong to resist breakup, a secondary objective will be the investigation of floc strength and particularly those chemical physical factors that may increase the resistance of floc to the shearing forces of turbulence. One of the limited aims of this phase of the research will be the development of a suitable device to measure or provide an index of floc strength.

2.0876, DILUTE SOLUTION REACTIONS OF NITRATE ION AS APPLIED TO WATER RECLAMATION
F.C. GUNDERLOY, North Amer. Rockwell Corp., *Canoga Park, California* 91304

1. Undertake a literature search of dilute solution reactions of the nitrate ion. Two groups of reactions are expected to be useful: Reduction of nitrate to nitrite, and deamination to nitrogen.

2. Carry out a testing program using the most promising chemical systems to determine feasibility of chemically decomposing nitrate ion.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0877, PHOTOCHEMICAL METHODS FOR PURIFYING WATER
J.M. SMITH, Univ. of California, School of Engineering, *Davis, California* 95616

The primary objective is to evaluate photochemical processing as a means of tertiary water treatment. The first phase is to establish the most promising operating conditions (lamp-reactor geometry, residence time, light intensity, oxidizing agent, sensitizer, etc.) for a continuous flow process. These data would be obtained in a small, pilot-plant reactor, feed for which would be secondary effluents from Sacramento-area wastewater treatment plants. Preliminary runs with water from the Northeast Area Treatment Plant of the Sacramento County Sanitation District have indicated a reduction in COD of 25-50% without sensitizer of supplementary oxidant. When Fe ion was added as a sensitizer, the reduction was greater, but not markedly so. These initial results, admittedly not at optimum conditions, indicate that the photochemical method is a promising one. Of particular importance is the possibility of a process not using a sensitizer.

As a secondary objective, and with time permitting, studies would be made to evaluate photochemical decomposition as a process for removing resistant pesticides from water, especially wastewater.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0878, HYDROLOGY OF CACHUMA RESERVOIR
E.R. HEDMAN, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

The objective of this project is to evaluate proposed air-injection systems to minimize thermal stratification in large reservoirs in order to (1) increase the dissolved oxygen content of the deep water, (2) prevent the development of dissolved hydrogen sulfide and other sources of bad taste and odor, and (3) reduce the concentration of phytoplankton populations in water to be withdrawn and treated for domestic use. The chemical and biological effects of air injection in lake water will be studied. Field and laboratory experiments will be conducted to study the effects of air injection in a controlled environment. The changes in phytoplankton populations, water quality, and temperature will be studied with varied thermal stratification.

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of California.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0879, TREATMENT OF MUNICIPAL SECONDARY EFFLUENT BY REVERSE OSMOSIS
A.N. MASSE, Los Angeles Co. San. Dist. 21, *Pomona, California*

Reverse osmosis through a cellulose acetate membrane is being investigated as a process for removing dissolved inorganic and refractory organic materials from a municpal secondary effluent. A 5000 gpd unit, using the spiral membrane configuration, manufactured by the General Atomic Division of General Dynamics Corporation has been run at 400 psi on secondary effluent passed through a 10-micron filter and on secondary effluent passed through a column of granular carbon for removal of dissolved organic mterial. The secondary effluent receiving only a filtration pretreatment both fouled and plugged the membranes and the feed channels. Considerably more success was obtained when the unit was fed carbon-treated secondary effluent. Over 80 per cent of the 4000 gpd feed is recovered as product having a TDS of less than 50 ppm, and a COD of less than 5 ppm. A similar study is in progress on a fiber-glass tube unit spplied by Havens Industries. The results are similar but troubles have been encountered because of tube rupture.

2.0881, INFLUENCE OF SEDIMENTATION UPON THE PRODUCTION OF GAME FISHES
R.E. VINCENT, Colorado State University, State Coop. Fishery Unit, *Fort Collins, Colorado* 80521

2. WATER QUALITY

A pre-treatment population inventory was made of all species of fishes in Blue Water Creek in 1963. Sections of the watershed were then treated to reduce the amount of sediment in the watershed. Post treatment inventory will then be made of all fish species with emphasis upon species composition, numbers and age class, standing crop and productivity. Fish population information can be correlated with the changes in sediment discharge and attendent changes in water temperatures, food organisms, etc.

The project is being conducted in Blue Water Creek in south-central Montana.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0882, SELF-ADJUSTING AND SELF-CLEANING FILTER FEASIBILITY STUDY
J.D. BANE, Hercules Incorporated, *Wilmington, Delaware* 19899

This six-month program will determine the feasibility of a unique self-adjusting and self-cleaning filtration system for reducing water pollution from combined sewer systems during storm runoff conditions. The new concept is based on the expansion and leakage characteristics of Hercules' filament-wound, resin-bonded Spiralloy structures-used successfully in a number of missile motors and commercial applications. Basically, the Spiralloy filter will be designed and fabricated to expand at low pressures to yield numerous micron-size openings. During stormflow, the filter will expand in proportion to the hydraulic head and permit leakage of filtered water to a separate chamber for subsequent chlorination before final water-way discharge. The suspended and settleable solids will be retained by the filter and transported to a sewage treatment plant. Self-cleaning will be accomplished by the interior surface condition and a centerbody to impart high shear velocities along the filter wall. This approach offers an economical solution to the combined sewer pollution problem.

This program is being performed at Allegany Ballistics Laboratory (ABL), Box 210, Cumberland, Maryland. ABL is a government-owned laboratory managed by Hercules Incorporated, Chemical Propulsion Division.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0883, ON-SITE PURIFICATION OF GROUND WATER AND DOMESTIC SEWAGE BY AEROBIC MICRO-FAUNA
R.P. ECKELS, Unknown Inst. Or Indiv. Grant, *Florida*

Approximately 1/3 of all Americans obtain their drinking water raw from private wells or from untreated public sources, and approximately as many dispose of household wastes at the site, in privies, cesspools, septic tanks, etc. For most of these citizens, full, municipal-type treatment of either water or sewage is a remote and impossible dream.

We utilize the conventional concrete septic tank (500-1000 gal. capacity) as the structural framework for a simple device. With structural modifications and additions and a colony of aerobic micro- fauna, the concrete box is used to purify either raw water or domestic sewage. Both processes could be carried on side by side. The process is odorless and without insect or other nuisance, and requires only minute amounts of either mechanical or electrical power. No process chemicals are required or necessary.

The final effluent is potable: clear, colorless, tasteless, odorless, substantially free of microbial and suspended solids, completely non-pathogenic. It is equally utilizable for generation of hydroelectric power, for agricultural irrigation, spraying or flooding; for recreation (boating, swimming, fishing); for recharging underground aquifers or for direct addition to a supply of potable water.

2.0884, EFFECTIVENESS OF IODINE FOR DISINFECTION OF PUBLIC WATER SUPPLIES & TO DETERMINE PHYSIOLOGICAL EFFECTS ON A HUMAN POPULATION
A.P. BLACK, Univ. of Florida, Graduate School, *Gainesville, Florida* 32601

This project is to demonstrate the effectiveness of iodine for the disinfection of polluted water supplies and to evaluate the several variables affecting such procedures to demonstrate the physiological effects, if any, on a significant number of consumers over an extended period of time. The water supplies of three state institutions will be disinfected with iodine and every sixth person of more than 600 inmates will be selected for intensive medical evaluation.

2.0885, WATER POLLUTION CONTROL BY THE SECLAR METHOD
UNKNOWN, Sogreah, *Grenoble, France*

Research and experimentation on the Seclar water pollution control method to produce potable water, and develop prototypes of 5.5 cubic meters/per hr.

SUPPORTED BY Aquaval Society - France

2.0886, PHYSICAL-CHEMICAL PHENOMENA ASSOCIATED WITH ORGANO-COLLOIDAL SURFACE INTERACTIONS
G.W. BAILEY, U.S. Dept. of the Interior, Federal Water Quality Admin., *Athens, Georgia* 30601

Investigation is concerned with the elucidation of the nature of interactions between organic compounds and colloidal surface, particularly with regard to sorption, degradation and/or decomposition. It will be possible with such information to predict the behavior of a given organic in, through, and/or off soil surfaces and thus predict the possibility of such a compound entering water courses and causing a water pollution problem. With such information, it will be possible to predict the mechanism of pollutant transportation in water courses.

Three sorption parameters are being investigated: (1) Molecular orientation (by means of X-ray diffraction); (2) Bonding type (spectrophotometrically); (3) Thermodynamic properties (by means of calorimetry and/or appropriate thermodynamic relationships).

Adsorption isotherms will be run in addition to supplement the above parameters in formulating mechanism(s) of adsorption.

The applicability of the above findings to improving existing water and waste treatment processes will be tested.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0887, EVALUATION OF MEDIA FOR RAPID FILTRATION OF WATER
T.F. CRAFT, Georgia Inst. of Technology, Engineering Experiment Station, *Atlanta, Georgia* 30332

Sand, anthracite, and mixed media are being evaluated in pilot filters. To ensure direct application of the results to full-scale operations, the filters are installed at a municipal water treatment plant where a continuous supply of coagulated and settled water is available. Head loss and turbidity are the major parameters being measured. Variables of the media to be investigated include particle size, particle size distribution, combinations of more than one material, and the manner of grading. One of the filters is designed so that reverse grading can be achieved. The filters are operated in parallel so that conditions in the water during a run are identical. Findings to date verify that head loss increases more slowly with reverse graded than with normally graded sand.

SUPPORTED BY Georgia Institute of Technology

2.0888, RADIOTRACER STUDIES ON RAPID SAND FILTRATION
G.G. EICHHOLZ, Georgia Inst. of Technology, Water Resources Center, *Atlanta, Georgia* 30332

This project continues a current research project aimed at determining the distribution and dynamics of fine particles of given sizes in rapid sand or anthracite filters of controlled composition and size distribution. The effect of surface condition, flow rate, bed composition, and chemical exchange on primary deposition and subsequent elution of suspended matter in the

filter is being studied by means of radiotracers. Continuous readings on deposition curves and detailed analysis of succeeding layers of the filter as well as the collection of dissolved tracer ions are employed to observe the behavior of the test filter under representative conditions. Analysis of the filtration curves makes it possible to evaluate appropriate kinetic coefficients for the adsorption and exchange mechanisms.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0889, BUFFER CAPACITY IN AQUATIC ECOSYSTEMS
F.G. POHLAND, Georgia Inst. of Technology, Environmental Resources Center, *Atlanta, Georgia* 30332

The proposed research will investigate the use of buffer capacity for evaluation of pH changes resulting from the influx of pollutants into aquatic ecosystems. The study will be divided into three phases: (1) Development of a mathematical model for buffer capacity; (2) Experimental verification of the model with laboratory analyses and simulations; (3) Elaboration of the application of buffer capacity for analysis of the quality and ultimate use of natural waters.

The model for buffer capacity will be developed by identifying the types and relative concentrations of various acids and bases indigenous to or discharged into the aquatic ecosystem. Analytical solutions to expressions describing the component buffer systems will be simplified by defining limits of application, introducing appropriate approximations and programming for computer analysis. Total species concentration will also be described on the basis of alkalinity and/or acidity measurements in order to facilitate application of the method in terms of routine analytical parameters.

Biological processes will be simulated in the laboratory and used to provide verification of the model for buffer capacity and to help establish limits of application. These results will then be extrapolated to natural water systems and techniques will be proposed for the use of buffer capacity in water quality control and treatment.

2.0891, EFFICIENCY OF FIBROUS BED COALESCERS
W.M. LANGDON, Illinois Inst. of Technology, School of Engineering, *Chicago, Illinois* 60616

The object of the one year program is to produce a design for a complete coalescer unit. This design will be used to construct and test a small scale demonstration unit which will be operated on an actual industrial pollutant stream. The program will consist of the preparation of general plans, specifications, explanations, cost estimates, and a discussion of the anticipated performance in recovering finely-divided, insoluble liquid pollutants from the selected industrial source. The design must not only be effective and economical but also capable of adaption to the many different types of pollutants and conditions that may arise.

Project will begin June 1, 1970 and approximately May 31, 1971 it will end.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0892, NITRIFICATION--DISSOLVED OXYGEN RELATIONSHIPS
T.A. BUTTS, State Water Survey, *Urbana, Illinois* 61801

Earlier investigations have emphasized the importance of nitrification as a major sink on dissolved oxygen resources in several sectors of the Illinois River. Conventional secondary treatment implemented along the river may not maintain adequate DO levels commensurate with current water quality criteria. Assessments will be made of existing ammonia loadings on the river, and alternatives, including in-stream aeration, will be investigated.

SUPPORTED BY Illinois State Government - Springfield

2.0893, FACTORS INFLUENCING FREE-LIVING NEMATODES IN WATER SUPPLIES
R.S. ENGELBRECHT, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

It has been observed that nematodes can be removed effectively by rapid sand filtration if their motility can be reduced. The use of various chemical agents, e.g., chlorine, bromine, copper sulfate and silver nitrate, on nematode motility is being evaluated in terms of nematode removal by subsequent water treatment processes. Results indicate that 3mg/l of free available residual chlorine, prior to coagulation, sedimentation and filtration, can eliminate more than 99 percent of the nematodes in the finished water as compared to about 66 percent in systems without chlorine. Copper sulfate was effective only when the hardness of water was low. Studies are being continued, using tap water, sewage treatment effluent, and stream water to determine the efficiency of different chemicals under various conditions, e.g., pH, organic and inorganic composition of the water.

2.0894, NITRATE REDUCTION IN THE VICINITY OF TILE DRAINS
B.A. JONES, Univ. of Illinois, School of Agriculture, *Urbana, Illinois* 61801

Various oxidizable substrate that can be used as filters for a tile drain will be studied in the laboratory to determine the potential of utilizing the biological denitrification process to reduce nitrates in the drain effluent.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0895, WATER SUPPLIES
E.R. BAUMANN, Iowa State University, School of Engineering, *Ames, Iowa* 50010

Methods are being developed for protecting individual water supplies and improving the chemical and physical quality of these waters. Methods that have been successful for treating municipal water supplies are usually not directly applicable or practical for individual systems. Among the methods studied is superchlorination-dechlorination for disinfection and sand filtration for iron and turbidity removal.

In studies of farm water supplies, techniques are being developed to measure chlorine, removal properties of activated carbon. Adsorption phenomena and chlorine removal characteristics of several types of carbon have been operated in the laboratory for removal of chlorine and precipitated iron to evaluate their combined effects on filter life.

In studies of small water supplies, laboratory water testing techniques are being developed to predict the life of precoat carbon filters in small water supply installtions. A laboratory test has been developed for measuring cake resistance of the suspended solids. A theoretical equation and computer program have also been developed for predicting filter life on the basis of the measured cake resistance.

Other physical properties of the powdered activated carbon used in precoat carbon filters are also being determined. These properties include surface area, particle size distribution, bulk density, and specific gravity. The relationships between these properties and the performance of the activated carbon are being evaluated. The objective of the research is to provide the basis for a specification for purchasing activated carbon to be used in precoat carbon filters.

An associated study concerns removal of iodine-131 from water using precoat carbon filters. This study is providing a basis for future investigation concerning the removal of pesticides using the precoat carbon filters; the pesticides used in these studies will be tagged with radionuclides.

2. WATER QUALITY

SUPPORTED BY Iowa State University

2.0896, DESIGN REQUIREMENTS FOR MUNICIPAL DIATOMITE FILTERS
P.E. MORGAN, Iowa State University, School of Engineering, *Ames, Iowa* 50010

This study was undertaken to determine the characteristics of municipal applications in which diatomite filters may be used successfully, to study the effect of various variables on filtration economy and effectiveness, and to outline a procedure for designing a plant to operate with maximum economy. A theory of diatomite filtration has been proposed and verified for use in designing plants for the filtration of raw and chemically treated water. In the current work, a computer program is being developed that will be used for determining the characteristics of a filter to operate at lowest cost. A truck mounted diatomite water treatment plant is being operated in the field to gather design data for typical municipal water applications: iron removal, surface water filtration, coagulated water filtration, and filtration of limesoda-ash softened water. These data will be fed into a computer to determine the economics of filtering such waters with diatomite filters.

Laboratory studies are being made to determine the hydraulic characteristics of filter cakes used in the removal of kaolin, montmorillonite, and other clays from water. The evaluation of coagulant and polyelectrolyte coatings for filter aids will be extended to determine the effects of pH and other factors on their removal of biological organisms and turbidity and on their hydraulic characteristics.

2.0897, A NEW TYPE OF DISINFECTANT FOR WATER SUPPLIES
J.L. LAMBERT, Kansas State University, School of Arts, *Manhattan, Kansas* 66502

The research will consist of the study of a safe, convenient new type of disinfectant for water supplies. The compounds to be studied are of the water-insoluble ion association type, containing a polyhalide ion of iodine, bromine or chlorine in combination with a quaternary ammonium anion exchange resin. The polyhalide ion would react on a demand basis with organic contaminants in the water, and release only the harmless halide ion into solution. Virtually complete kills have been attained from overloads of 10 to the 5th power to 10 to the 6th power of E. coli per ml on passage through a column of a triodide-resin combination. The effect on other enterobacteria and certain fecal streptococci are currently being studied. If desired, the halide ion released after bacterial reduction of the polyhalide ion could be retained downstream on another portion of anion exchange resin in the chloride or sulfate form.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0898, THE REMOVAL OF EXCESS NITRATES AND NITRITES FROM POLLUTED WATER
C.E. MELOAN, Kansas State University, Kansas Water Resou. Res. Inst., *Manhattan, Kansas* 66502

It is proposed to synthesize a modified nitron compound so it can be pearl polymerized. This material should be highly selective for removing nitrate and nitrite from water resources. The saturated bead is to be regenerated with NH4OH producing NH4NO3 which is of commercial value. Four other materials, Di(-Methyl-Naphthylamine), Cinchonamine, N-Diethyl Benzohydrylamine, and -Phenyl- - Diethyl Amino Ethyl-P-Nitro Benzoate will also be investigated.

In an attempt to understand the mechanism of the nitrate specificity, 4H-1,2,4-Triazole-3-Anilino-4,5-Diphenyl and 1,2,4-Triazolidine-1, 4-Diphenyl-2-Phenylimino will be investigated if the money holds out.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0899, FOAM SEPARATION FLOTATION OF COLLOID ORGANIC SYSTEMS
R.B. GRIEVES, Univ. of Kentucky, School of Engineering, *Lexington, Kentucky* 40506

The overall objective of this investigation is the establishment of definite design criteria for specific, continuous foam separation processes. The processes will include the foam fractionation-flotation of colloidal and soluble iron from water supplies, the ion flotation of hexavalent chromium from plating wastes, the foam fractionation of sulfate, sulfite, and lignin-containing wastes from pulp and paper mills, the ion flotation of free and complexed cyanide, and several additional processes, involving specific industrial waste constituents. The processes will be conducted on a batch and on a continuous-flow basis, establishing the efficiencies on the basis of effluent contaminant concentration, and on the quantity of influent lost into the foam stream. For each process an economic evaluation will be carried out, and definite recommendations on the applicability of each process will be made.

Based on previous work and on work currently being conducted, foam separation processes can become a vital part of industrial waste treatment systems. They have excellent potential for water clarification and for iron and manganese removal. This research will enable the design of full-scale processes for specific contaminants.

An additional phase of the investigation will be a feasibility study of the addition of low concentrations of colloidal particulates to wastewaters to enable the foam separation of weakly-surface-active organics.

2.0900, EFFECTS OF CHEMICAL IONS ON VIRUS INACTIVATION
O.J. SPROUL, Univ. of Maine, School of Engineering, *Orono, Maine* 04473

This project would determine the influence of chemical ions on virus inactivation in certain water and wastewater treatment systems and dieoff in natural water systems. The processes to be investigated would be ion exchange, phosphate removal from a secondary effluent and inactivation under high and low pH conditions.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

2.0901, LIVESTOCK FARMSTEAD WATER SYSTEMS
E.E. JONES, U.S. Dept. of Agriculture, Agricultural Engin. Res. Div., *Beltsville, Maryland* 20705 (313-012-B602)

OBJECTIVE: Develop design recommendations for farmstead water systems which will provide sanitary protection, efficient labor and water utilization and first-aid fire protection.

APPROACH: Develop water system design criteria which will provide uncontaminated water. These studies will include an investigation of methods and equipment for protection of the source of supply, provision of adequate sanitary protection, and the elimination of backsiphoning and cross-connection hazards. Develop design criteria to improve the first-aid fire fighting potential of the farmstead water system. This study will include the development of design recommendations which will allow local fire departments to use the farmstead system as a source of water in combating fires. Develop methods and equipment for efficient use of water and labor for cleaning livestock and dairy facilities. This study will include an investigation of such factors as surface configuration, pen shape, nozzle design and pressures.

PROGRESS: Further analysis of farmstead water use data indicates that desirable system capacity can be estimated with sufficient accuracy using demand factors of 100%, 50%, and 25%. Limited field progress was made in improving water utilization efficiency in livestock sanitation. Literature review has confirmed initial field and theoretical evaluations and strengthened mathematical models for rational analysis. Above bottom velocities of 3 fps, depth of flow to waste depth and duration of flow, are major factors determining average solids loading and effectiveness of

cleaning. The uncertainty of animal response to a given surface configuration makes full scale system evaluation necessary. Wells lacking adequate sanitary protection and serving as unauthorized uncontrolled recharge points cannot be disinfected by a disinfectant dosage based on bore volume only. Disinfectant must be forced into formation in sufficient concentration to disinfect the contaminated formation. Measurement of disinfectant residual on pumping after specified contact time is necessary to determine adequacy of disinfection.

SUPPORTED BY U.S. Dept. of Agriculture

2.0902, IMPROVEMENT OF ANALYTIC AND FEEDING METHODS FOR FLUORIDES
E. BELLACK, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Bethesda, Maryland*

The main objectives are to develop continuous feeding and analytic methods that will permit accurate administration of fluorides to domestic drinking water supplies. Other methods will also be refined to defluoridate high fluoride water.

There will be an opportunity to test various methods at the several rural school sites where the PHS Dental Division is checking the influence of high fluoride water used in the school.

Some effort will be made to refine the specific ion probes now used for continuous plant measurements as well as for laboratory purposes.

This has been a continuing project of many years and will continue to respond to technology problems in fluoridation.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0903, LONG TERM EFFECTS OF WATER FLUORIDATION IN GRAND RAPIDS, MICHIGAN
E. SCHIFFMANN, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *Bethesda, Maryland* 20014

The objective of this report is to determine long term effects of fluoridation by histological and chemical examination of rib, vertebra, and aorta of individuals residing for at least 20 years in a fluoridated area. These were compared with specimens from individuals resident in non-fluoridated areas. The project is now complete. The findings are that increased fluoride uptake occurred in both osseous and non-osseous calcified specimens from the fluoridated area compared to the non- fluoridated areas. Also there was no noticeable relationship between incidence of pathology and exposure to fluoride. Finally it appeared that exposure to fluoride produced no long deleterious effects.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0904, MECHANISM OF ORGANIC ADSORPTION ON ACTIVATED CARBON
J.T. COOKSON, Univ. of Maryland, School of Engineering, *College Park, Maryland*

Activated carbon is extensively employed for removal of dissolved organic substances from water, such as color, taste and odor compounds. The research objective of this project is to evaluate surface groups that exist on activated carbon for adsorption of these organics.

Activated carbon will be chemically treated to methylate and hydrolyze select surface oxides. The significance of these surface oxides as active sites will be determined by the capacity and adsorption rate of organic substances on treated and untreated carbons. The effect of variables such as pH and ionic strength will also be determined. This information will be analyzed to provide the mechanism for adsorption of color and odor substances on carbon, and the physicochemical nature of the active sites.

There is a need to continue research on the physicochemical nature of the surface of activated carbon, but of equal importance and the aim of this project is to determine the functional groups that act as sites for removal of most natural organic substances from water. The capacity of activated carbon can possibly be increased and maintained by regeneration practices if they conform to activation methods that establish surface groups responsible for adsorption.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0905, IMPROVEMENT OF QUALITY OF WATER RESOURCES BY A THREE-FOLD ATTACK - ADSORPTION, SEDIMENTATION AND MIXING
W.A. WOCKENFUSS, Univ. of Maryland, School of Engineering, *College Park, Maryland*

The proposal is an effort to get to the general problem of water purification through a three-fold attack. (1) Chemically, we would investigate a method to remove water pollutants by adsorption. (2) Through thermodynamics and study of flow conditions, we would investigate a method of preventing destruction of aquatic life and make a significant contribution to an area of investigation which has had little or no attention given to it as indicated by a lack of publications. (3) Through an investigation of settling velocities and settling characteristics of flocculent and nonflocculent materials, we would evolve design criteria for new improved sedimentation tanks.

2.0906, ASSESSMENT OF CHEMICAL POLLUTANTS IN UNDERWATER EXHAUST OF WATERCRAFT ENGINEERING
L.N. KUZMINSKI, Univ. of Massachusetts, School of Engineering, *Amherst, Massachusetts* 01002

There is need for the establishment of public policy to guide the growth of recreational boating and to protect all legitimate uses of the water resource. The overall objective of this project is to develop criteria to be used in establishing public policy on restriction of watercraft use in inland waters.

The research proposed herein will address itself initially to the problem of chemical substances in watercraft exhaust discharged under water. A first step is to determine the amount of such pollution disseminated as a function of watercraft horsepower and use. Subsequent laboratory work calls for the evaluation of removal efficiency by water treatment processes and toxicity testing. Field studies will be then carried out to correlate stress exerted on the water with pollutant build-up.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0907, STUDY ON FLUORIDE CONCENTRATIONS IN TOOTH ENAMEL
F. BRUDEVOLD, Forsyth Dental Infirm. for Ch., *Boston, Massachusetts* 02115 (NIH-70-2244)

Determine whether differences in dental caries experience in groups of adolescents native to communities with approximately 1 ppm fluoride and fluoride-deficient communal water supplies are related to the concentration of fluoride in the outermost surface of the enamel of permanent teeth.

Determine whether the differences in caries experience and any of the differences in enamel fluoride concentrations are associated with traces of molybdenum, vanadium, titranium, aluminum, zinc, copper, and iron in the water supplies.

Clinical dental examinations shall be conducted on approximately 150 Caucasian adolescents, aged 13 and 14 years, in each of 4 cities. The subjects shall be chosen from fluoridated Charlotte, North Carolina, and Danvers, Massachusetts, and from fluoride-deficient Rockford, Illinois, and Boston, Massachusetts. Children will be selected randomly from all the 13 and 14 year olds in Junior High Schools located in upper middle-class neighborhoods.

At the time of the clinical examinations, enamel biopsies shall be performed on the labial surfaces of the upper right central incisor of each child. The analyses will be done at pH 5.5 with and without addition of citrate, in order to determine presence of F complexers in the enamel.

2. WATER QUALITY

2.0912, EFFECTS OF ENVIRONMENTAL CHANGES ON BLUE-GREEN ALGAE
M.M. ALLEN, Wellesley College, Graduate School, *Wellesley, Massachusetts* 02181

Changes in evironment will be used to study the structure and function of the subcellular components of the blue-green algal cell, in an effort both to isolate and identify the components chemically and ultrastructurally, and to discover their functions in the cell in different physiological states. The primary experimental objects will be two axenic unicellular species, Anacystis nidulans and Gleocapsa alpicola, whose growth conditions are well defined. Pigment ratios, fine structure, granule formation and composition, and chemical composition of control cells grown under optimal laboratory conditions will be compared with those of cells grown or treated with variations in concentration of required inorganic nutrients, in light quality and intensity, and with mutagens. Such basic physiological information is necessary for application in the control of algal blooms in water supplies.

The localization of pigment molecules in the cell, and the pathway and control of pigment synthesis, will be studied by pigment analyses and electron microscopy of cells containing varying ratios of pigments. Efforts will be made to prepare pigment mutants to complement and enlarge the information obtained.

Of the many unidentified types of granules found in cells of blue- green algae, two specific forms which are observed in large quantities in cells grown under particular ecologically important conditions will be characterized in this study.

SUPPORTED BY U.S. National Science Foundation

2.0913, SAND FILTRATION OF DISCRETE SUSPENSIONS
J.A. BORCHARDT, Univ. of Michigan, School of Engineering, *Ann Arbor, Michigan* 48106

This research is a continuation of a laboratory study on sand filtration. New techniques have been developed for media placement which have resulted in extremely reproducible head loss values under similar flow and impurity levels. This had made possible the extension of our work into regions of low turbidity.

The magnitude of the surface charge effects can now be separated from other gross bed response factors and hopefully a better insight into the filtration mechanism will result.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0914, ADSORPTION FROM AQUEOUS SOLUTION
W.J. WEBER, Univ. of Michigan, School of Engineering, *Ann Arbor, Michigan* 48106

The broad objective of the research is the definition and description of adsorption phenomena associated with the uptake of organic pollutants from waters and wastewaters by active carbon, and the delineation of factors which govern rates and equilibria of adsorption from aqueous solution.

The studies include a detailed investigation of the adsorption process and of the mass-transfer properties of different adsorption systems, and a detailed comparison of various conditions of operation from the points of view of efficiency and effectiveness of removal of persistent organic pollutants.

The factors of 'selectivity' of active carbon for certain types of organic solutes and of 'competition' for adsorption among the various solutes of a multi-component solution are of major concern for the present studies. In addition, and related both to the selectivity and to competitive effects, the nature and role of surface functional groups in adsorption are to be studied in detail.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0915, DEVELOPMENT NEUTRON ACTIVATION TECHNIQUES FOR INVESTIGATION OF WATER CLARIFICATION
L. HEMPHILL, Univ. of Missouri, School of Engineering, *Columbia, Missouri* 65202

A program of study, designed to investigate the course, nature and extent of clay mineral coagulation-flocculation by lime-alum reagent has been proposed. It is the object of this experimental study to determine colloidal clay material per se in solution using neutron activated clay. Direct measurement of clay mineral turbidity will provide new methods for determining turbidity in natural waters, calibration of filter efficiency and comprehensive evaluation of organic reagents (coagulation and filter aids) for water treatment.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0916, OXYGENATION OF AQUEOUS BODIES USING LIQUID OXYGEN
W. GARNER, Midwest Research Institute, *Kansas City, Missouri* 64110

This is a proposed study of the parameters controlling the transfer of liquid oxygen (i.e., LOX) to dilute aqueous solutions. The study would include measurements of the oxygen transfer coefficient, design of suitable oxygenation equipment, development of application techniques, and process-cost calculations;

this last item would, in turn, permit accurate comparisons of the costs of accomplishing various levels of oxygen enrichment with LOX vs. mechanical aeration or compressed gaseous oxygen.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0917, BRACKISH WATER PURIFICATION BY BIOLOGICAL FUEL CELL POWERED ELECTRODIALYSIS
W.A. SCHELLER, Univ. of Nebraska, School of Engineering, *Lincoln, Nebraska* 68508

Purification of brackish water containing 1000-5000 ppm of salts by electrodialysis appears to be more economical than any of the present day distillation techniques, but it is still expensive. A reduction in the water costs might be realized if a useful byproduct were produced in the water purification process.

The primary objective of the proposed research is to investigate the possibility of using an electrodialysis cell for brackish water purification in conjunction with a biological fuel cell powered by microorganisms capable of living in the brine effluent from the electrodialysis unit, feeding on cellulose containing materials such as hay, corn stalks, etc. and suitable for processing into cattle feed or feed supplement. Furthermore it is planned to investigate the effect of operating variables on the performance of the electrodialysis unit within the range of voltage-current-power capabilities of a battery of biological fuel cells. Finally, using the experimental results as a basis, economic evaluations will be made in order to determine the economic optimum arrangement of electrodialysis units and biological fuel cells. This is a five year program from fiscal 1966 through fiscal 1970.

2.0918, PURIFICATION OF LOW QUALITY WATERS BY FOAM SEPARATION
T.E. WILSON, Rutgers the State University, School of Engineering, *New Brunswick, New Jersey* 08903

The proposed research will involve laboratory scale experiments of both the batch and continuous type. Removal of turbidity, color and bacteria will be studied using both natural and lab-prepared water. Kinetic data from the batch studies will be used to develop a suitable continuous flow system. The constituents of the raw water will be varied and their effect, as well as the effect of air bubble size will be studied.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0919, THE EFFECT OF CHLORINATION ON TREATED ORGANIC CHEMICALS
E.L. BARNHART, Hydroscience Incorporated, *Westwood, New Jersey* 07675

It is proposed to conduct a study to determine any adverse effects that might result from the chlorination of certain industrial chemicals either before or after biological treatment.

Present Objectives: 1. To determine the effect of selected organic chemicals and their degradation products on chlorine demand and disinfection efficiency. 2. To determine, for selected chemicals, in which cases it is possible to form chlorinated compounds during disinfection of the treated effluent. 3. To determine the physical properties and degradation rate of any chlorinated compounds found. 4. To determine the influence of persistent chlorinated compounds on the stream biota. Several levels of life forms will be considered.

The study will be conducted in three phases: Phase I will mix selected compounds before and after biological treatment with chlorine and measure chlorine demand and disinfection efficiency; Phase II will collate persistent chlorinated organics and describe their properties; Phase III will determine the impact of persistent chlorinated organics on the receiving environment.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0920, EVALUATION OF PUMPING EFFECTS IN MALAGA BEND AREA, NEW MEXICO
J.S. HAVENS, U.S. Dept. of the Interior, Geological Survey, *Albuquerque, New Mexico* 87106

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with state and local agencies in New Mexico.

Purpose: To determine the improvement of the quality of water in the Pecos River as the result of lowering the head of the brine aquifer discharging a saturated brine into it and to determine if the pumped brine is confined within the disposal area.

Methods: Observation wells completed in the brine aquifer and in shallower aquifers are used to monitor water-level fluctuations and quality of water changes. Seepage runs are made to monitor the quality of water in the Pecos River.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0921, CONCENTRATION AND ANALYSIS OF PESTICIDES AND OTHER RECALCITRANT MOLECULES IN WATER SUPPLIES BY ULTRAFILTRATION
V.H. EDWARDS, Cornell University, School of Chemical Engineering, *Ithaca, New York* 14850

This research seeks to determine whether ultrafiltration or reverse osmosis can be used effectively to concentrate aqueous solutions and suspensions of pesticides and other biologically and chemically recalcitrant organic molecules for purposes of more accurate and sensitive sampling and analysis of water supplies. A second objective will be the development of a prototype design for a field sampling device based upon the principles developed in this research.

Principal elements in this research will include: 1. Screening of various commercial ultrafiltration membranes for suitability in concetration of selected test pesticides. 2. Study of the influence of pertinent variables (such as pH, temperature, pesticide concentration, and mineral and sediment content and compostion) on ultrafiltration flux rates and rejection efficiency of memoranes for selected pesticides. 3. Implementation of these results into the preliminary design of a prototype field sampling device. (Subsequent research based upon this work will be directed towards construction and field evaluation of this device and technique.)

2.0922, ARTIFICIAL RECHARGE OF TREATED SEWAGE WATER AT BAY PARK, NEW YORK
G.D. BENNETT, U.S. Dept. of the Interior, Geological Survey, *Mineola, New York* 11501

The objective is to evaluate the feasibility of and develop optimum methods for injecting water from highly treated sewage-plant effluent into deep artesian sand aquifers of the Magothy(?) Formation (Upper Cretaceous) of Long Island. This formation, which is the principal source of the water supplies for Nassau and western Suffolk Counties, is being pumped intensively and locally is being invaded by salty water. Extensive artificial recharge through injection wells with reclaimed waste water may be needed for water conservation and to create fresh- water pressure ridges to retard sea water.

Water from sewage-plant effluent will be further treated to a potable quality and then injected under pressure through specially designed wells (with fiberglass casings) under various experimental conditions. Data on hydraulic and geochemical results of the injection will be collected using observation wells and special in-situ geochemical sensors.

This research is part of the program of water resources investigations being carried on in cooperation with the County of Nassau, N.Y.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0923, MASS TRANSFER ANALYSIS IN REVERSE OSMOSIS OPERATION
C. TIEN, Syracuse University, Research Institute, *Syracuse, New York* 13210

The main objectives of this work are: (1) To obtain analytical expressions for the rate of production of pure water from waste water by reverse osmosis operation in terms of operating variables under turbulent flow conditions. (2) To study the effect of natural convection on a reverse osmosis system. (3) To determine the most promising geometrical configurations of the system and the most optimal operating conditions.

2. WATER QUALITY

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0924, REUSE OF PLANT EFFLUENT AND COOLING WATER BLOWDOWN AS PROCESS WATER
W.J. DAY, Fiber Industries Incorporated, *Charlotte, North Carolina* 28201

An existing facility provides treatment for the combined sanitary and equalized chemical process waste waters from a synthetic fiber manufacturing plant. Treatment facilities consist of extended activated sludge aeration basins, clarifier, polishing ponds, and aerobic sludge digestion basin, and a sludge holding pond.

The project will evaluate treatability of this waste in a plastic media trickling filter, feasibility of algae removal from the polishing pond effluent by use of microscreen filters, feasibility of BOD, COD, color, odor and taste reduction in the final effluent by use of powdered carbon for the purpose of ultimate reuse of the effluent as process makeup water, and chromate reduction of cooling tower blow-down to permit treatment in the waste treatment plant.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0925, EVALUATION OF FIELD WATER PURIFICATION SYSTEMS
N.S. HURST, U.S. Navy, Medical Field Res. Lab., *Jacksonville, North Carolina* 28542

Technical Objective: Evaluate methods of water purification suitable for use by individual Marine troops in the field and improve the taste of purified water.

SUPPORTED BY U.S. Dept. of Defense - Navy

2.0926, WATER QUALITY IMPROVEMENT - KINETICS AND MECHANISM OF THE CHLORINATION-DEGRADATION OF UREA AND URIC ACID
F.H. RATHMANN, North Dakota State University, School of Chemistry, *Fargo, North Dakota* 58102

The objective of this project is to determine the mechanism and chlorination-degradion of urea and uric acid and the intermediate products formed prior to eventual conversion to harmless and non-noxious substances. Aqueous solutions of pure urea and pure uric acid will be made up and mixed with solutions of Cl2, HOCl, and NaCl. Intermediate products formed by the reactions will be determined by oxidation, by ultraviolet and visible spectroscopy, by adsorption chromatography, by polarography, and by diminuation and disappearance of the tests used for the initial materials. The course of the reactions will be followed mainly by changes in the ultraviolet spectra and in the pH of the solutions. Urea will be determined by direct oxidation or by the xanthydrol method. Uric acid will be determined by ultraviolet spectroscopy, or by the phosphomolybdate and other methods.

Samples of water taken weekly from swimming pools in the Fargo- Moorhead area will be analyzed by standard methods to determine the levels of urea, uric acid, and of the intermediate chloro-urea and chloro-uric acid degradation products in those waters. The course of reactions will be followed by the same methods used for the ideal solutions of pure urea and uric acid.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0927, REMOVAL OF ORGANIC CONTAMINANTS
P.W. BUELOW, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Cincinnati, Ohio* 45213

The primary objective of this project is to field test monitoring techniques and evaluate full-scale plant testing of treatment processes for removal of organics and in water supplies. For the present, this study will be confined to helping local waterworks officials and State Health Department people evaluate the efficacy of activated carbon monitor units for detecting organic removal and to concurrently study the various full-scale methods for reducing organics from surface water such as replacing the sand in filters with granular activated carbon.

This has been a continuing project since 1967 and will have to continue indefinitely.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0928, BEHAVIOR AND CONTROL OF CONTAMINANTS IN SURFACE WATERS
J.K. CARSWELL, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Cincinnati, Ohio* 45213

This project is designed to determine the behavior of contaminants of public health importance in surface water used as a raw water source for municipal drinking water and to develop engineering techniques for controlling these contaminants. Laboratory-, pilot-, and field experiments will be carried out, to accomplish the above-mentioned long- range objectives. Behavior of water quality parameters will be studied in controlled laboratory experiments under conditions typical of those found in nature. The findings of these experiments will be confirmed in large-scale experiments and in the field. Engineering techniques for control of water quality will be investigated in small- and large-scale field studies. Early studies will be concerned with the behavior of indicator organisms in thermally stratified reservoirs and the usefulness of artificial destratification to the water supply industry as a means of raw water quality control. This project was started in October 1967 and is a continuing project.

2.0929, STUDIES CONCERNING THE EFFECTIVENESS, STABILITY AND RELIABILITY OF GERMICIDAL COMPOUNDS
G. BERG, U.S. Dept. of the Interior, *Cincinnati, Ohio* 45244

Technical Objective: Determine the effectiveness, reliability, and stability of emergency water purification and germicidal compounds for Army use.

SUPPORTED BY U.S. Dept. of Defense - Army

2.0930, DESTRUCTION OF INFECTIOUS VIRAL NUCLEIC ACID BY IODINE
G. BERG, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

It has been reported that iodine destroys viruses by reaction with the protein coat, and that it does not react with viral nucleic acids. Since iodine is used as a water disinfectant, we have undertaken to determine whether viral nucleic acid, imprisoned in an inactivated shell, presents a hazard in disinfected wastewaters and renovated waters.

Polio virus 1 (Mahoney) has been concentrated by ultracentrifugation. The viral RNA has been extracted with phenol from the intact virus, and purified by precipitation with salt-saturated ethanol. We have shown that the viral RNA is much more resistant to the disinfecting action of iodine than the parent virus from which the RNA was obtained.

A large volume of coxsackievirus A9 has been concentrated by ultracentrifugation, and its RNA will be extracted and tested for sensitivity to iodine.

Polio virus RNA and coxsackievirus RNA will be tested for sensitivity to other halogens, also.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0931, DISINFECTION OF RENOVATED WASTEWATER
R.L. BUNCH, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

In some areas the treatment of municipal wastewater for direct reuse is inevitable. Recreational use of renovated wastewater will also increase in areas which lack surface water. Regardless of the use of reclaimed water, the health needs for sewage purification and disinfection must be met at all times.

The primary objective of this project is development of methodology to produce a pathogen-free effluent from waste treatment processes. This process must be economically feasible, yield an effluent free of hazardous toxic components and as far as possible yield an effluent that does not introduce factors undesirable to aquatic environments.

The merits of chlorination, ozonation, C102-process, and any other promising and practical disinfection process will be evaluted in terms of efficacy, economy, practicability and relative freedom from undesirable after-effects.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0932, BIBLIOGRAPHY ON FLUORIDATION OF PUBLIC WATER SUPPLIES
I.R. CAMPBELL, Univ. of Cincinnati, School of Medicine, *Cincinnati, Ohio* 45221

The purpose of this project is a continuing survey of the worldwide literature concerning the occurrence and biological effects of the inorganic fluorides and of all aspects of fluoridation of water supplies, and alternative methods of caries prevention with fluorides. The main objective is the preparation of informative abstracts of publications of major interest, i.e, those applying to dental and general health, so as to provide as complete as possible a record of the pertinent fluoride literature, equipped with detailed indexes. These abstracts are made available at nominal cost or gratis to interested libraries and scientists in universities and other research organizations as an aid in keeping up with the rapidly growing and widely scattered literature.

The overall product of this work serves as the basis for the publication of state-of-the-art reviews with the assistance of an Advisory Editoral Board, to provide reliable information for dentists, physicians, community leaders, and others concerned with the welfare of their community on the safety, effectiveness and significance of fluoridation of public water supplies and on the role of fluoride in general health. The availability of the abstracts has materially assisted authorities in the field to prepare critical reviews on this subject.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0933, CONCENTRATION OF CHEMICALS BY FLOC FORMING ORGANISMS
P.R. DUGAN, Ohio State University, Graduate School, *Columbus, Ohio* 43210

This study is an investigation of the metabolic activities of floc forming organisms with regard to their ability to lower biochemical oxygen demand (BOD) and to remove toxic metal ions from solution in relation to aerobic waste treatment processes. This may have particular relevance to specialized waste treatment situations such as those encountered in milk processing wastes and metal processing wastes. It is planned to examine the relative importance of the floc matrix (zoogleal material), compared to the same microbial cells not in zoogleal form, to the aerobic treatment process.

The influence of environmental variables in the floc forming process is also being studied.

2.0934, FORMATION OF DENSE SETTLED SLUDGE BY LIME - TREATMENT OF SYNTHETIC ACID MINE DRAINAGE
K. SVANKS, Ohio State University, School of Engineering, *Columbus, Ohio* 43212

The voluminous sludges obtained in current methods of lime neutralization and iron removal in the treatment of acid mine drainages constitute one of the major drawbacks to this process. The objectives of this research are to investigate means of obtaining dense sludges when acid mine drainages are treated with lime. Initial laboratory investigations have shown that with proper preadjustment of the ferric- ferrous ion ratio, lime neutralization can lead to the formation of FE3O4 or FeOOH, depending on pH control and on the concentration of aluminum in the drainage. It appears probable that dense sludges can be obtained in both cases. Sludge quality and iron removal will be studied as a function of total iron and acidity, ferric-ferrous ratio prior to neutralization, pH control during neutralization, and aluminum content. Due to the extremely slow rate of oxidation of ferrous ion by oxygen under acid conditions, organisms of the Ferrobacillus- Thiobacillus group will be utilized to catalyze the rate of ferrous ion oxidation in the preneutralization adjustment of the ferric-ferrous ratio.

2.0935, TERTIARY TREATMENT BY FLOCCULATION AND RAPID SAND FILTRATION
D.F. TOSSEY, Dayton Department of Water, *Dayton, Ohio* 45402

The purpose of this project is to demonstrate the feasibility of tertiary treatment at a municipal trickling filter plant. Coagulation, flocculation, sedimentation and filtration principles will be applied to trickling filter effluent and final plant effluent utilizing an existing scale model unit. Tests will be conducted both with and without the use of chemicals. Various filter media and flow rates will be studied.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0936, EFFECT OF SURFACE GROUPS ON ADSORPTION OF POLLUTANTS
R.W. COUGHLIN, Lehigh University, School of Engineering, *Bethlehem, Pennsylvania* 18015

Activated carbon is the most promising material which has been investigated for adsorbing biologically undergradable organic compounds from waters and waste waters. Of the many different commercially available carbons which have been used for these studies, some have shown markedly higher adsorptive capacities than others (two to three times on a per-gram basis). Presumably, these differences are due to varying specific surface areas, variable types of surfaces and different functional groups on the solid surfaces. It is proposed herein to investigate the influence of type of surface and nature of functional groups on the surfaces as they affect the adsorption of typical biologically undergradable organic compounds on activated carbon and on other promising adsorbents. The utimate goal of this research will be to identify those functional groups and surfaces which are most efficacious for adsorbing specific compounds. This information will indicate how better materials can be designed for specific adsorption tasks, provide expanded and better means of surface regeneration and establish guides for selecting solid adsorbents to achieve a particular adsorption goal.

2.0937, TREATMENT OF COAL MINE WATERS TO MEET CURRENT COMMONWEALTH WATER DISCHARGE REQUIREMENTS
H.L. LOVELL, Penn. State University, Graduate School, *University Park, Pennsylvania* 16802

The detailed engineering design and plans are complete. Construction for phase 1, excavation and construction of lagoons at the site near Hollywood, Clearfield County, Pennsylvania is essentially completed.

Phases 2,3,4, and 5 (the installation of unit operations and instrumentation) have been bid and work will proceed shortly. Completion of construction is anticipated by spring 1969.

The plant will encompass a highly instrumented series of unit operations so designed that it will be capable of functioning through at least six different flow sheets. Emphasis is being placed on solid- fluid separations which comprise the highest cost operations, both capital and operating, and which offer the most difficult technical and engineering problems.

SUPPORTED BY Pennsylvania State Government

2.0938, FACTORS AFFECTING MINE DRAINAGE AND THE GROUND WATER INTERACTIONS IN SELECTED AREAS OF WESTERN PENNSYLVANIA (PART 2)
R.R. PARIZEK, Penn. State University, Graduate School, *University Park, Pennsylvania* 16802

As shown by a previous study, a stratification of ground water flow in the strip-mined bituminous coal field of Pennsylvania may exist that may effectively divert acid mine drainage pollution to deep ground water reservoirs. Further, opportunities

for neutralization were shown to exist. These considerations may lead to the establishment of a potable ground water supply in an area afflicted with surface acid mine drainage. To test these hypotheses a specialized water monitoring system was installed to accurately evaluate the aquifer characteristics, to determine the aquitards in the area and to sample ground water by chemical analyses to determine the extent and effect of acid mine drainage pollution.

A related study will investigate the field conditions under which pyrite remains stable and does not decompose to produce acid mine drainage. Samples of iron disulfide from an area containing strip mines yielding alkaline drainates will be analyzed to determine the reason for the stability; hence, gain an insight to acid mine drainage abatement.

SUPPORTED BY Pennsylvania State Government

2.0939, CARTRIDGE FILTRATION FOR IRON AND MANGANESE REMOVAL

F.J. DELUISE, Univ. of Rhode Island, School of Engineering, *Kingston, Rhode Island* 02881

The primary aim of this project is the development of a practical, effective cartridge-type filter system for the removal of iron and manganese from ground water supplies. Bench-type laboratory studies have indicated that such a system should be possible. This study will employ a flow system in which a feed pump, dosing pump, contact coil and cartridge filter are the principal elements. Various chemicals will be used to oxidize the iron and manganese. The proper combination of system elements, sizes and conditions will be sought to provide both an acceptable effluent and a minimum pressure drop across the filter.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0940, DIRECT METHODS FOR THE ENUMERATION OF SALMONELLA IN WATER

V.J. CABELLI, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Narragansett, Rhode Island* 02882

A series of laboratory and field studies will be performed towards developing and evaluating a membrane filter method for the enumeration of Salmonella species in marine and fresh waters. This method is needed for the conduct of investigations relating the sanitary quality of marine and fresh recreational waters to enteric disease in the swimmers. It also is needed as another means of monitoring (potable waters) and their sources.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0941, EFFECT OF CHLORINATION ON HUMAN ENTERIC VIRUSES

O.C. LIU, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Narragansett, Rhode Island* 02882

The effect of chlorination on viruses has been repeatedly investigated in the past two decades. The weaknesses of these studies are: (a) the number of viruses examined was very small as compared with the available viruses isolated from human feces, thus generalization of this limited information may be hazardous. (b) the most unfavorable conditions for the virus existing in nature have never been taken into consideration. Under any or a combination of these conditions, a virus could be much more resistant to this treatment than has been demonstrated in the laboratory. This project is undertaken at the request of the Army Corps of Engineers as a part of the feasibility study of the supplementary supplies for Washington, D.C. area in the year 2000. The major objective for this project is to compare the resistance of 35 strains of human enteric viruses to chlorine.

Two types of water will be used as the suspending media for all viruses: the conductivity water (chlorine demand free) and the Potomac estuarine water (coagulated and filtered in the Washington, D.C. water treatment plant). Water samples will be characterized for chlorine- demand, chlorine content, total solid, pH, turbidity, COD, and the like. Immediately before each experiment, all aliquots of each water sample will be adjusted to pH 7.8. Half of the aliquots will be kept at 22 degrees C and the other half at 2 degrees C. Each virus strain will be added to the water samples to achieve a concentration of approximately 10,000 infectious doses/ml. The treatment of the virus-laded water samples will consist of 0.5 and 1.5 mg/l of chlorine for two hours. The rates of viral devitalization will be determined in appropriate assay systems and the free residual chlorine read by an amperometric titrator.

Initially six representative virus strains will be tested parallelly in both the conductivity and the Potomac estuarine waters. The chlorine effect on these viruses in two waters will be critically compared and evaluated. From this analysis, the procedures for testing the remaining viruses will be determined.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0942, EFFECT OF CHLORINATION ON HUMAN ENTERIC VIRUSES

H.R. SERAICHEKAS, U.S. Environ. Protection Agcy., Northeastern Water Hyg. Lab., *Narragansett, Rhode Island* 02882

The objective of this project is to determine and compare the resistance of human enteric viruses to free chlorine in drinking water. This information will furnish the basis for guidelines for disinfection of water supplies and safeguarding the supplies from transmission of human enteric viruses.

Accomplishment in FY-71: During the past 18 months, 25 strains of human enteric viruses were tested for their relative resistance to 0.5 mg/l of free chlorine under identical experimental conditions: suspending in partially purified Potomac River water adjusted to pH 7.8 and incubated at 2 degrees C. A wide range of resistance to the chlorine treatment was detected among the tested viruses. For instance, 2.7 min. were required to kill 99.99% of a reovirus under these conditions, whereas 43.7 min. were required to kill the same amount of a coxsackievirus (A6). The resistance of the remaining viruses fall between these two extremes. Thus it is clear from these data that the degree of chlorine resistance of any virus is entirely unpredictable.

Plans for FY-72: It is planned to test an additional 20 strains of virus for the resistance to chlorine. Further, it became apparent that chlorine resistance of the naturally occurring virus may be substantially different from those grown and prepared in the laboratory. As a preliminary study, the chlorine resistance of several types of poliovirus from human feces will be determined under controlled conditions and compared with the same types of virus prepared in the lab. These results should shed more light on the problems encountered in the field.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0943, KINETICS OF BIOLOGICAL FILTERS

J.F. ANDREWS, Clemson University, School of Engineering, *Clemson, South Carolina* 29631

Since the trickling filter is an aerobic biological treatment process which depends upon the action of attached microorganisms for the removal of organic waste products, the overall process may be represented by the simplified reaction equation: organisms plus substrate plus oxygen yields new cells plus metabolic waste products.

It is the objective of this research project to study the kinetics of biological filters by observing the influence of the three reactants on the rate of removal of organic products by attached microorganisms and use this data to evaluate a proposed mathematical model for trickling filters. In view of the fact that the microbial population of a trickling filter is responsible for the removal of organic waste products, it should be possible to express this removal in terms of microbial growth kinetics.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0944, THE REMOVAL OF IMPURITIES IN TRICKLING FILTER EFFLUENTS

T.M. KEINATH, Clemson University, School of Engineering, *Clemson, South Carolina* 29631

Over the past ten years application of electrophoretic mobility measurements in control of water treatment processes has been investigated by Black and associates and Riddick, primarily, under various conditions using natural or synthetic waters. It is

considered to be materially effective in improving efficiency of the removal of impurities in both secondary and tertiary waste treatment.

It is planned, as a first step, to examine the colloidal properties of the particulates in a trickling filter effluent, using the effluent from Clemson University waste treatment plant, both before and after passage through the final clarifier. This plant discharges to a large impoundment which is used for water supply and recreation. Investigation of the chemical properties of the waste from the sampling points will be a necessary adjunct to the electrophoretic mobility measurements and microscopic examination of the particulates. Initial work will be extended to include treatment of the trickling filter effluent using coagulants, such as ferric sulfate, and further investigation of the colloidal properties, to obtain information on the conditions for optimum removal of impurities, along with the use of zeta potential as a control process in treatment.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0945, THE VORTEX CHAMBER AS A GRIT REMOVAL DEVICE FOR WATER TREATMENT
P B. ZIELINSKI, Clemson University, School of Engineering, *Clemson, South Carolina* 29631

The objective of this study is to determine the efficiency of the free surface vortex chamber as a grit removal device for treatment of waste or supply water. This study also includes a consideration of the effectiveness of this flow to retain the lighter organic particles in suspension and be retained in the flow through the chamber for conventional treatment.

The measured parameters will include the variables necessary to define adequately the vortex flow according to existing methods, which include a measure of the total head, flow rate, circulation, and physical properties of the fluid. Measured batch quantities of a known size gradation of light particles in the form of wax and plastic spheres and organic media along with inorganic particles will be combined with the flow at various rates prior to the entrance into the vortex chamber. Quantities of collected or settled particles will be measured. Particular attention will be directed toward the effectiveness of grit removal over a wide range of variation of flow rates, a condition of operation which is normally found in treatment plants.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0946, VIRUS REMOVAL-WATER AND WASTEWATER
W.A. DREWRY, Univ. of Tennessee, School of Engineering, *Knoxville, Tennessee* 37916

The proposed research project involves laboratory studies of virus removal by several conventional water treatment processes that also are or can be used as wastewater treatment processes. Processes studied will include flocculation, chlorination, activated carbon adsorption and ion exchange. The virus used will be f2 bacteriophage which is effective against E. coli.

It is proposed to use a single virus, a single assay technique and well defined experimental procedures in order to provide a valid basis for determination of the relative effectiveness of the various treatment processes.

Laboratory studies on three different waters will include: 1. Flocculation studies (Jar Tests) using several commonly used chemical coagulants and a representative cross section of approved coagulant aids. 2. Concentration effect and rate of kill chlorination studies. 3. Activated carbon adsorption studies both on a batch (Jar Test) and continuous flow column basis. 4. Ion exchange removal studies using continuous flow columns.

2.0947, REFRACTORY ADSORPTION ON CHEMCOKE
G.T. FISHER, Vanderbilt University, School of Engineering, *Nashville, Tennessee* 37203

The adsorption properties of chemcoke, an apparent competitive material for activated carbon, will be examined for refractory materials.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0948, ELECTROPHORETIC CLARIFICATION OF WATER
E.A. HILER, Texas A & M University System, School of Agriculture, *College Station, Texas* 77843

This research involves a study of the utilization of the electrophoretic method for pollutant removal from natural waters. Electrophoretic clarification is effected by removal of charged colloidal particles from water as the suspension is passed through a dc electric field.

The purpose of this research is to investigate the removal of colloidal clay, bacterial and pesticidal pollutants from water by the electrophoretic method. The objectives are as follows: (1) development of an optimal electrode arrangement based on results of theoretical and basic experimental research; (2) characterization of various contaminants present in typical natural waters; and (3) evaluation of the efficiency of removal of these pollutants by the electrophoretic method.

This study will provide a critical evaluation of the feasibility of the electrophoretic method of water clarification.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0949, ADSORPTION OF ORGANIC COMPOUNDS ONTO SOLIDS FROM AQUEOUS SOLUTIONS
J.P. WIGHTMAN, Virginia Polytechnic Institute, Graduate School, *Blacksburg, Virginia* 24061

The proposed research involves a study of factors effecting adsorption of organic compounds from aqueous solution. The compounds selected for study contain functional groups representative of water contaminants. Several solids of different surface energy will be studied.

The surface area, surface constituents, and structural elements of each solid will be established. The measurement of the amount of organic compound adsorbed and the heat of adsorption is proposed.

The results should ultimately support a model for solution adsorption by which predictions concerning the selectivity of adsorption of a given compound in water by a given solid could be made.

2.0952, HIGH FLUX RO MEMBRANE WITH SALT REJECTION PROPERTIES
J.E. JONES, U.S. Army, Mobility Eqp. Res. & Dev. Ctr., *Fort Belvoir, Virginia* 22060

Technical Objective: Study potential membrane materials exhibiting high flux and salt rejection characteristics. Determine flux decline slopes and salt permeation constants and optimize material best adapted to military field intended use.

SUPPORTED BY U.S. Dept. of Defense - Army

2.0953, DETERMINE FEASIBILITY CHARACTERISTICS OF TUBULAR RO PROCESS
D.C. LINDSTEN, U.S. Army, Mobility Eqp. Res. & Dev. Ctr., *Fort Belvoir, Virginia* 22060

Technical Objective: Conduct exploratory investigation of the various tubular configurations to determine the technical feasibility of the various geometrical tubular modules and select the most optimum arrangement for the multi-purpose military water purification requirements.

SUPPORTED BY U.S. Dept. of Defense - Army

2.0954, DEVELOPMENT OF METHODOLOGY FOR ISOLATION OF VIRUSES FROM WATER
W. JAKUBOWSKI, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Gig Harbor, Washington* 98335

The efficiency of poliovirus removal from water by adsorption to iron oxide, kaolin, bentonite and a polyelectrolyte (PE60- an insoluble cross-linked copolymer of maleic anhydride) will be determined. The adsorbents will be tested under varying conditions of pH, ionic strength and nonviral protein level. A centrifugation procedure will be used to separate the virus-adsorbent complexes from the reaction mixtures. The percentage recovery of virus from adsorbent will also be determined. The adsorbents will be compared for efficiency of removal and recovery of low polio-virus levels from large volumes of freshwater and seawater. The adsorbent-virus complexes will be removed from suspension by filtration through fiberglass prefilter pads. Investigations will also be conducted on filtration of virus suspensions through layers of adsorbent preformed on the surface of the filter pad. Parameters to be studied include flow rate and adsorbent bed depth.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0955, PROVIDE A COMPENDIUM OF OIL SPILL TREATING AGENTS COVERING ABSORBENTS, DISPERSANTS, SINKING AGENTS, COMBUSTION PROMOTERS, GELLING AGENTS, ETC
P.C. WALKUP, Battelle Memorial Institute, *Richland, Washington* 99352

Manufacturers' information and documented field experience on the use of various types of treatment agents were compiled. About 100 commercially available products were included and the information on each includes chemical and physical characteristics, effectiveness, limitations, and toxicity.

SUPPORTED BY Amer. Petroleum Institute

2.0956, NITROGEN REMOVAL AND IDENTIFICATION FOR WATER QUALITY CONTROL
D.A. CARLSON, Univ. of Washington, School of Engineering, *Seattle, Washington* 98105

The specific research objectives are to use a biological denitrification system to (1) define a theoretical kinetic model for denitrification based on information from pure culture studies using Ps aeruginosa, (2) establishing an emperical equation for denitrification in mixed cultures based on the pure culture research and mixed culture pilot studies, and (3) development of analytical techniques for measuring nitrogens and other water quality parameters using modern optical, acoustical and microwave techniques.

Laboratory and pilot studies will be used and instrumentation developed to apply equations and mechanisms to field studies for continuous monitoring.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0957, THE USE OF PULP MILL SLUDGES AS EXTENDERS FOR CORRUGATING MEDIUM
L. LENEY, Univ. of Washington, School of Forestry, *Seattle, Washington* 98105

The objectives are to enhance reduction of stream pollution by the development of a technical basis for economic utilization of pulp and paper mill sludge. Sludges of various mills which represent sludge types will be mixed as extenders in varying proportions with semi- chemical pulps. Hand sheets of corrugating medium will be made and tested according to TAPPI standards. The characteristics of the corrugating medium will be determined by all feasible means to understand how the sludge influences the sheet properties. From this it may be possible to predict the best mix for any sludge of known composition thus encouraging its utilization in a marketable product.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

D. WATER MANAGEMENT AND POLLUTANT DISPERSAL

Dispersal of Effluents, Hydrologic Mixing, Disposal on Soil Waste Fields, Dilution of Pollutants, Assimilative Capacity, Ocean Dispersion, Self-purification. Includes Management of Polluted Natural Waters to Improve Quality.

2.0958, CONSERVATION OF WATER AND REDUCTION OF POLLUTION BY USE OF SOLVENT SYSTEMS FOR COLORING TEXTILE MATERIALS
W.S. PERKINS, Auburn University, School of Engineering, *Auburn, Alabama* 36830

The purpose is to study organic solvent systems for coloring of textile materials for the purposes of conservation of water supply, reduction of effluents, and improvement in quality of dyed textiles.

In Fiscal Year 1971 solvents for selected disperse dyes will be screened. Selected dyes will be applied to polyester substrates from selected solvents by batch dyeing procedures. Dyed substrates will be tested for appearance, fastness, and handle.

The kinetics and thermodynamics of the dyeing process will be evaluated as they are related to the economics of the process.

In Fiscal Year 1972 the study will be extended to direct dyes on cellulosic substrates.

Consultations regarding the construction of facilities for application of dyes from solvents and for solvent recovery are within the scope of the project.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0959, STUDY OF ASSIMILATIVE CAPACITY OF ARCTIC AND SUB-ARCTIC STREAMS
P.J. FREY, U.S. Dept. of the Interior, Federal Water Quality Admin., *College, Alaska* 99701

Information on the effects of extreme environments (have periods of darkness or of light, total ice cover for nine months of the year, low maximum water temperature) on a river's capacity to assimilate pollution, and on the organisms which inhabit the streams and are responsible for the degradation of pollution will be obtained so that it will be possible to predict and evaluate the effects of pollution on these streams.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0960, THE EFFECTS OF SUSPENDED SILTS AND CLAYS ON SELF-PURIFICATION IN NATURAL WATERS
A.P. MILLER, Univ. of Alaska, Inst. of Water Resources, *College, Alaska* 99735

The proposed research plan involved laboratory investigations using natural and synthesized sediment laden waters to determine their effects upon the self-purification process in rivers and streams. The primary hypothesis to be tested will be whether

adsorption of particulate contaminants and bacteria upon the sediment particles will enhance the biodegradation of these materials requiring extracellular enzyme production. Effects of temperature will be studied once the adsorptive capacities for the bacteria and organic substances are known. Biological activity will be determined by respiration rates measured under various conditions of known adsorptive capacity, bacterial population, and substrate concentrations.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0961, LIMNOLOGY--NUTRIENT-BIOTIC RELATIONSHIPS IN THE UPLAKE REGION OF BEAVER RESERVOIR
L.R. AGGUS, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Fayetteville, Arkansas* 72701

Preliminary limnological studies in the extreme upper reaches of Beaver Reservoir suggest a level of biological activity much higher in the remainder of the impoundment. Waste materials after secondary treatment enter the reservoir via the White River. The long theoretical detention time of Beaver Reservoir (1.3 years) permits ample time for considerable nutrient assimilation in the extreme uplake region. Attempts will be made to correlate standing crops of bacteria, plankton, benthos and shad with several physical-chemical parameters. Nitrogen- phosphorus uptake by these organisms will be estimated.

Appropriate sampling methods will be used to estimate desired parameters from five stations in the uplake region of Beaver Reservoir. Sampling will be conducted biweekly from June through the period of fall overturn. Monthly or bimonthly sampling may then be conducted until thermal stratification occurs in the spring.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0962, REHABILITATION OF A BRINE-POLLUTED AQUIFER
R.C. SMITH, State Soil & Water Cons. Comm., *Little Rock, Arkansas*

The project is expected to rehabilitate a brine-polluted aquifer. The aquifer is used to supply domestic and irrigation water and has been polluted by oil field brine water. The project is located near Garland City, Miller County, Arkansas.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0963, DECISION PROCESSES IN WATER QUALITY MANAGEMENT
R.M. MALES, Engineering Science Inc., *Arcadia, California* 91006 (C-1736)

This study will evaluate, using dynamic simulation techniques, the decision-making processes at both the agency and group or individual levels in the multi-agency system of water quality management. Both existing and hypothetical organizational schemes will be considered in terms of their management functions as they relate to objective implementation interrelationships. Techniques and tasks which can be used to evaluate and improve the decision-making process of groups and individuals will be developed.

The results of this study will have broad applications in all sectors of the water quality management field.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0964, MIXING PROCESSES IN ESTUARIES
H.B. FISCHER, Univ. of California, School of Engineering, *Berkeley, California* 94720

This research will study the underlying procesees which cause mixing amid dispersion in estuaries through a re-examination of the fundamental mixing and transport processes. A laboratory flume will be used to study the effect of partial stratification on turbulent mixing, both in the vertical and transverse to the main flow direction. In addition, the convective patterns in a simplified model estuary will be observed in detail, in an attempt to combine knowledge of turbulent mixing and convective patterns to predict the overall dispersive pattern. Methods will be sought to predict the values of transfer coefficients in real estuaries, and to show the effect on these coefficients of engineering modifications to the estuary. Results of these studies will be used to improve present methods for forecasting pollutant dispersion.

SUPPORTED BY U.S. National Science Foundation

2.0965, MIXING PROCESSES IN SATURATED AND UNSATURATED SOIL-WATER SYSTEMS IN RELATION TO POLLUTION
J.W. BIGGAR, Univ. of California, Agricultural Experiment Sta., *Davis, California* 95616 (CA-D0-WSE-2451-SG)

OBJECTIVE: Analyze the transient nature of the mixing of dissolved organic and inorganic ions in water flowing through saturated and unsaturated soils. Impose the presence of thermal gradients and analyze the transient nature of the mixing of two fluids at two different temperatures for similar and dissimilar salt concentrations. Ascertain the nature of the porous material by comparison of mixing of thermally different solutions with chemically dissimilar solutions.

APPROACH: Attempt to describe the system by means of thermodynamic and hydrodynamic models with the aid of computer analysis. Particular attention will be given to the physical properties of the fluids used. This project will augment previous and present work conducted under Regional Projects W-68 and W-82. Experimental laboratory work to test theory and provide ranges of values for parameters will be obtained.

PROGRESS: Studies of the mixing of thermally different fluids in porous medium has been completed. Although the analogies exist between the mixing of chemically and thermally different fluids in porous media, the conditions are sufficiently different to provide additional knowledge of the mixing phenomenon. Axial thermal conductivities may have significant effect on the overall heat transferred at slow velocities. The ratio of kz to kr (longitudinal to radial thermal conductivity, respectively) remained constant at (1.1) for all flow velocities and for all soils. Heat transfer by mass flow was the dominant mechanism and the different fluid mixing patterns account for the behavior of the apparent thermal conductivities. Miscible displacement of Cl and HTO through soil at different flow rates and total salt concentration has been used to test a new model for dispersion based on mobile and immobile salt and water zones in the soil. The new model appears to be a big advancement in dispersion theory.

2.0966, FEASIBILITY ANALYSIS OF INCINERATOR SYSTEMS FOR RESTORATION OF OIL CONTAMINATED BEACHES
R.M. ROBERTS, Aerojet General Corporation, *El Monte, California* 91734

The purpose of this program is to establish if combustive systems can find effective application in the restoration of shore areas that have been despoiled by large oil spills. Included in the study is the establishment of the physical and thermodynamic properties of contaminated shore material and the design of conceptual incineration systems which would be economically feasible in renovating such material. All types of beaches and various configurations of combustors are being considered in this analysis. Appropriate testing will be performed to verify conclusions derived from theoretical premises. Contingent upon the feasibility established for the approach, the system selected as optimum in cost-effectiveness will be reduced to preliminary design drawings. This work was initiated in and will be completed in fiscal year 1969-1970.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0967, SOCIO-ECONOMIC STUDY OF MULTIPLE USE WATER SUPPLY RESERVOIRS
R. STONE, Ralph Stone & Company, *Los Angeles, California* 90025 (C-1633)

The research objective is to determine and evaluate the social and economic costs and benefit associated with varying degrees of recreational use of water-supply reservoirs while main-

taining safe potable water quality standards. Representative examples of four classes of reservoir will be studied in depth to define the socio economic cost-benefits of multi-versus single-purpose reservoir use to the community, region, and nation, and the relationship of incremental water treatment requirements to the individual water consumer. The interrelationships between water quality standards, treatment costs, community recreation and water needs, alternative recreational reservoir use, economic activity generated, and projected pollution loads and demographic change will be defined to develop general principles for optimum water-supply reservoir management. Formulation of a DARE Algorithm, mathematical model, and computer program will ensure maximum applicability of the principles developed.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0968, CHEMISTRY OF HYDROSOLIC METALS IN NATURAL WATER

J.D. HEM, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

Certain metallic elements readily precipitate as oxides or hydroxides at the pH and redox potential normally occurring in aerated natural water. The most common of these elements, iron, manganese, and aluminum are being studied under this project.

One aim of the research project has been to provide a more complete understanding of the factors affecting solubility of iron and manganese in natural water so that the problems of removal from water supplies can be approached more logically.

Phases 1 and 2 of this project, the study of iron and manganese chemistry respectively, have been completed. Phase 3, concerned with aluminum chemistry, is in progress.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0969, HYDROUS METAL OXIDES - THEIR GEOCHEMISTRY AND EFFECT ON WATER QUALITY

E.A. JENNE, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

As the use and reuse of water increases and hence the degree of pollution increases, it becomes increasingly important to understand the processes controlling the concentration of trace metals in waters, as recent medical findings show that the trace metal concentration of water has pronounced effects on human health.

Previous studies have indicated that hydrous oxides of iron and maganese are the principal control on the concentrations of many of the trace metals in fresh waters and soil solutions. Current studies show: 1) that hydrous microcrystalline manganese dioxide can sorb certain metals very rapidly; and 2) provide a chemical means of determining the amount of the various oxides in sediments.

Determination of the time-capacity of stream sediments and water impoundment sediments for trace metal sorption and relationship of these data to the hydrous oxides present will be studied. Evaluation of the relative importance of organic matter in trace metal fixation will be determined.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0970, SAN FRANCISCO BAY

D. MCCULLOCH, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

State(s) to which the work listed herein pertains: California.

The principle objectives of this combined geologic and hydrologic study of the San Francisco Bay estuary are: to describe the past and present geologic framework of the bay, including the three dimensions of its bedrock basin and sediment fill and its tectonic and sedimentation history; to describe the physical, chemical, and in part, biological properties of the water mass; and to evaluate the relation between these geologic, hydrologic and geochemical factors and the physiography, bathymetry, quality of water and biota of this complex estuary.

2.0972, A STUDY OF THE DEEP CIRCULATION AND DEEP FISH POPULATIONS IN THE PACIFIC OCEAN

R.A. SCHWARTZLOSE, Univ. of California, Graduate School, *San Diego, California* 92038 (AT(11-1)-34,)

Knowledge of the deep near-bottom ecology and the ocean circulation is important to the basic understanding of the heat and energy exchange between the deep and upper layers, the nature and behavior of the organisms living in darkness and under high pressures, the factors involved in disposal of radioactive waste, and the conditions of the operation of deep submergence vehicles and other deep-sea floor developments of many kinds, etc. Also, the low level of understanding and quantification of organic productivity in the volume of the ocean is a vital defect in our basic grasp of the total biological process in the sea, and this deficiency may be alleviated through our approaches.

We plan to continue to photograph deep near and bottom animal communities and measure currents near the deep bottom. The measurements will be carried out during cruises that lend themselves to the use of autonomous vehicles. At present there are plans for measurements in the deep basins on the continental borderland off Southern California, the region between New Zealand and the Antarctic and in the western Indian Ocean near the Comoro Islands.

RESULTS: Over 200 deep current measurements have been made in areas from the north Central Pacific at 43 degrees N to south of South America at 63 degrees S. The measurements in general are beginning to show a pattern of the movement of deep bottom water from the central South Pacific entering the North Pacific through a narrow channel north of Samoa about 300-400 miles. Under the California Current the deep flow appears to be generally southeastward. The average speeds are 2-4 cm/sec. The deep benthic fish populations photographed by our baited camera continue to show fish populations much larger than anticipated. The deeper the photographs, the variation in species becomes less and less with the Grenadier being the predominate fish below 2000 m.

SUPPORTED BY U.S. Atomic Energy Commission

2.0973, TECHNICAL FEASIBILITY AND ANALYSIS OF COSTS AND EFFECTIVENESS OF BULK TRANSPORT OF SEWAGE TREATMENT PLANT SLUDGE AND DREDGING SPOILS

E.J. WASP, Bechtel Corporation, *San Francisco, California* 94119

This project is concerned mainly with the development of regional land and ocean pipeline disposal systems for digested sewage sludge and maintenance dredgings. Two study cases are presented, namely, a land disposal system for Northeast Ohio (Cleveland-Canton) and an ocean disposal system for the Baltimore-Washington region. A systems approach is used, in which collection, transportation, and disposal aspects are examined in light of technical, economic and social requirements. Various transport modes are compared, including pipeline, ocean tankers, railroads, and trucks

To a lesser extent, the study also considers the expansion of such systems to include fly ash and water treatment plant sludge. Present methods and costs of disposal for all four wastes are reviewed. Environmental criteria is presented for examining both land and ocean sludge disposal alternatives in terms of a general solution for two broad metropolitan regions, namely, the Great Lakes region from Buffalo to Milwaukee and the Atlantic Coast region from Boston to Norfolk.

Results of a loop test program utilizing 12" and 16" pipe for pumping digested sludge fly ash, and sludge-fly ash slurries are included, as well as corresponding rheological tests with a 1/2" small tube viscometer and a rotational lab viscometer. A procedure for predicting head losses is given, as well as a review of the state of the art of pipelining of waste materals.

Project began in fiscal 1968 and will end in fiscal 1970.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0974, ANALYSIS OF MOUND GEOMETRY UNDER A RECHARGE BASIN

R. SINGH, San Jose State College, School of Engineering, *San Jose, California* 95114

The central aim of this research is to predict analytically the changing positions of the water table over a region during the artificial recharge of excess rain or waste water.

For unconfined aquifers the Dupuit-Forchheimer assumptions may lead to large errors. For recharge problems the delayed dewatering may be relatively unimportant, but the vertical component of the velocity cannot be neglected. Hence the formulations of the recharge problems would be made following the Boulton's approach in such a way that the vertical component of the velocity would be accounted for. The following two cases will be investigated: (i) Unsteady recharge from a long pit, and (ii) Unsteady recharge from a circular pond.

2.0977, INVESTIGATIONS OF ALGAE INHIBITING MATERIALS

T.R. BARTLEY, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

Attached aquatic organisms seriously reduce the carrying capacity of irrigation and water distribution structures. Laboratory and field studies show that by coating these structures with appropriate materials containing toxicants the organisms will not develop on the coated area. Coatings under study include antifouling paints, direct metal coatings to concentrate incorporation of toxicants in the concrete surface, and various other materials applied to the surface of the submerged concrete. The most promising results to date indicate that certain antifouling paints, a vinyl-resin system of cuprous oxide or tributyl tin oxide, applied to submerged concrete will provide long-term inhibition of algae attachment. The present program has progressed sufficiently to provide recommendations for routine field use of specified materials on submerged concrete structures. These antifoulifg coatings are presently limited to small areas, such as concrete weirs and flumes, because of cost.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0978, RIVER BASINS - SOUTH FORK DAM

D.A. HOFFMAN, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

Two Forks Reservoir will be constructed on the South Fork Platte River to impound water for flood control, M&I, fish and recreational uses. The dam and reservoir will be key elements in a complex of reservoirs and streams going from mountain parks downstream through a large metropolitan area. There is a great need for background information in order to make recommendations for construction and operation to protect and enhance environmental objectives. A small study will be initiated to develop the data needs for a management model of the South Platte River from its head waters through Antero, Eleven Mile Canyon, and Cheesman Reservoirs, the connecting mainstream through the city of Denver, and on through a highly irrigated farm area to the Colorado-Nebraska stateline. The model will be used to develop a management program which will include Two Forks and Narrows Reservoirs and Chatfield Dam. The operation of Two Forks for water quality, fish and recreational benefits in Denver will be included. The study will be contracted with a resource organization.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0979, WATER QUALITY CONTROL BY SELECTIVE WITHDRAWAL AND REAERATION

D.L. KING, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

Purpose: To investigate by means of physical and mathematical models and prototype measurements the movements of water through reservoirs and to investigate new and existing methods for reaction of streams and reservoirs.

The growing demand for sediment-free water and water at controlled temperatures and/or dissolved oxygen content requires a knowledge of the movement of water through reservoirs. Studies will be made to determine the effects of reservoir geometry and tributary waters on temperature stratification, to develop selective withdrawal techniques, and to develop methods of reoxygenation of rivers downstream from dams.

A general purpose research facility is being used to study the basic principles of temperature stratification, density currents, and patterns of flow approaching outlets at different levels.

2.0980, RESEARCH INTO THE ECOLOGICAL ASPECTS OF PRECIPITATION MANAGEMENT

H.L. TELLER, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

Development of a plan for the systematic study of the effects a precipitation management plan may have upon the ecology of the San Juan Mountains area of Colorado.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0981, ECONOMIC AND INSTITUTIONAL ANALYSIS OF WATER QUALITY STANDARDS AND MANAGEMENT

K.C. NOBE, Colorado State University, Environmental Resources Center, *Fort Collins, Colorado* 80521

This research project will study in depth several agricultural pollution situations in Colorado and will identify for particular reaches of streams, economic optimum methods and levels of water quality management, including consideration of identifiable externalities involved and alternative means of pollution control. Comparison of the implicit optimum quality standard for the various pollution parameters investigated will indicate the extent to which adopted standards are compatible with efficiency criteria and will provide valuable information to state and federal water pollution control agencies in future reviews of existing water quality criteria.

Paralleling investigation of the economics of water quality standards will be an examination of the effectiveness of institutions and arrangements for administering and enforcing the Water Pollution Control Program. This examination will describe the legal basis for pollution control; appraise the adequacy of state statutes; assess coordination between units of federal, state and local government; judge the adequacy of the pollution monitoring system and its adaptability to emerging problems; analyze the procedures for enforcement; and assess the administrative

costs of the program. Identification of strengths and weaknesses should reveal desirable modifications for more effectively managing water quality in the state.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0982, WIND EFFECTS ON THE DISPERSION OF PARTICULATE POLLUTANTS IN TURBULENT OPEN-CHANNEL FLOW

E.J. PLATO, Colorado State University, School of Engineering, *Fort Collins, Colorado* 80521

This is a study of the dispersion of solid particles in a liquid stream. The flow in the stream is turbulent with a free surface. Air is blown across the free surface in such a manner as to create waves in the water and thus to stimulate the turbulence generated by wind over streams. A quantitative understanding is sought through experimentation for the effect of wind on the diffusion of particles in the water.

The results should lead to data which can be used in the solution of the diffusion aquation in open channel flow with and without wind. A measure of the increase due to wind in diffusivity can be obtained in this way. The effect of wind on oxygen absorption in the stream is also to be investigated.

SUPPORTED BY U.S. National Science Foundation

2.0983, REAERATION IN OPEN CHANNEL FLOW

R. RATHBUN, Colorado State University, U.S.D.I. Geological Survey, *Fort Collins, Colorado* 80521

The capacity of a body of flowing water for assimilating biodegradable wastes depends heavily on the supply of dissolved oxygen which is required for the decomposition of organic material by bacteria. The amount of oxygen available for this purpose in turn depends on a complex balance among a number of processes which include various sources and sinks, and also the inflow and outflow of dissolved oxygen by convection. The principal sources augmenting the dissolved oxygen supply are atmospheric reaeration, and photosynthetic production by aquatic organisms, mainly green plants. Typical sinks depleting the supply, some of which are due to man-made pollution, are respiration of bacteria and algae, benthal deposits, and chemical oxidation.

The oxygen balance can be described qualitatively by a fundamental continuity equation. Before this equation can be used with confidence for predictive purposes, however, much remains to be learned about the source and sink processes, how they relate to one another, and how they relate to measurable physical and biochemical characteristics of a stream system.

This project is concerned with investigating the reaeration process in open channel flow, with particular emphasis on natural surface reaeration. Although no fundamental research on the biochemical processes involved in the oxygen balance is contemplated, they must be accounted for.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0984, SEDIMENTATION AND CONTAMINANT CRITERIA FOR WATER RESOURCES PLANNING AND MANAGEMENT

H.W. SHEN, Colorado State University, Environmental Resources Center, *Fort Collins, Colorado* 80521

To study the effect of vegetation on flow rate, sediment yield and dispersion of pollutant in watershed.

2.0985, GRAND VALLEY SALINITY CONTROL

G.V. SKOBERBOE, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00031)

OBJECTIVE: Demonstrate that the mineral quality of the Colorado River can be improved by lining irrigation canals and other water conveyance channels. Evaluate the effectiveness and general applicability of this method of salinity control.

APPROACH: In three selected study areas, irrigation canals and other water conveyance channels will be lined to control the major source of recharge to the near-surface aquifers; thereby minimizing the quantity of flow through mineral yielding geological formations and reducing the gradient which forces saline water into the Colorado River. Detailed field observations and measurements will be made to evaluate the effectiveness of lining in preventing seepage and the reduction in salinity to the Colorado River.

PROGRESS:

SUPPORTED BY Colorado State Government

2.0986, FLOW IN POROUS MEDIA IN RELATION TO DRAINAGE DESIGN AND DISPOSAL OF POLLUTANTS

H.R. DUKE, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Fort Collins, Colorado* 87101 (SWC-020-DFC-5)

OBJECTIVE: Investigate the hydraulic properties of porous media as related to design of drainage systems and the disposal of agricultural pollutants based upon suitable mathematical description of relationships among pertinent variables; and reduce to field practice, theories, principles and concepts developed.

APPROACH: Investigations will be conducted in the laboratory and field. The portion dealing with drainage design criteria involves use of laboratory flumes and models to stuudy functional relationships between permeability and soil water content or fluid pressure. Existing drainage equations will be examined for adequacy in accounting for saturated and unsaturated flow where possible; ways and means will be developed to reduce drainage theories and concepts to field practice. Field investigations concerning movement of agricultural pollutants in water, under both unsaturated and saturated conditions, will also be conducted, cooperating with other scientists.

PROGRESS: No significant findings - Porous media flume was utilized by graduate student for basic studies relating to the infiltration process.

SUPPORTED BY U.S. Dept. of Agriculture

2.0987, ECOLOGICAL EVALUATION OF MULTIUSE WATERS RECEIVING PRIMARY TREATMENT EFFLUENT PRIOR TO A MAJOR FLOW INCREASE

J.D. BUCK, Univ. of Connecticut, Marine Sciences Institute, *Groton, Connecticut* 06340

The research will involve a biological and chemical evaluation of an estuary which currently serves multiuse, i.e., recreation, aesthetics and disposal of effluent from a primary sewage treatment plant. Updating of the plant to secondary treatment and chlorination within 2 years will increase effluent flow 10-20 fold. This extra load of fresh water and inorganic enrichment may produce serious ecologic inbalance of the cove such that none of the above uses will be appropriate for these waters. An adjacent cove which receives no gross input of sewage effluent will be used as a control. This comparative before hand survey will allow an assessment of the the present status of macro-and micro- organism populations in the 2 areas and may provide information on the use of various components of the ecosystem as indicators of the presence of effluent or early stages of eutrophication.

Field studies will include biweekly sampling of water and sediment and determination of temperature, salinity, pH and dissolved oxygen. Various groups of bacteria, phytoplankton and bottom invertebrates will be enumerated. Nitrate, phosphate and BOD values will be determined also.

Based on the present biological, chemical and physical status of the cove, some assessment will be made of the ability of these waters to receive and assimilate or transport a significant increase in effluent without initiation of eutrophy and subsequent loss of multiuse value.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0988, WASTE WATER RENOVATION POTENTIAL OF FOREST SOILS PREDICTED BY THEIR CHEMICAL AND PHYSICAL PROPERTIES

D.E. HILL, Conn. Agric. Expt. Station, *New Haven, Connecticut* 06504 (CONH00415)

OBJECTIVE: Measure removal of substances from percolating waste water by exemplary forest soils. Relate removal to CEC observed in test tube or to distribution of clay and organic matter--and hence CEC--in the profile.

APPROACH: Synthetic sewage will be percolated through 1x3 foot undisturbed cores of upland, terrace and alluvial soils of varied texture and fragipans. Removal of ions by cores will be compared to CEC of bulk samples. Failing to observe simple relation, scientist will observe heterogeneity of CEC and water paths in cores and seek means of predicting renovation potential of soil profiles.

PROGRESS: Six undisturbed forest soil cores of widely varying physical and chemical properties continue to be leached with a synthetic sewage effluent that contains Ca, Mg, Na, K, NO(3), Cl, SO(4), PO(4) and HCO(3). After leaching 6 months with 52 one-inch increments, renovation capacity of all soils decreased but differed between soils. All soils removed virtually all PO(4) and K, while NO(3) and Cl leached through, except in the Cheshire soil which still removed 90 per cent of the NO(3) added. Up to 90 per cent SO(4) was removed by Paxton and Cheshire soils; little SO(4) was removed by the others. Up to 35 per cent Na was removed by Paxton and Stockbridge soils; little Na was removed by the others. About 80 per cent Ca and Mg were removed in early leachings by all soils; removal remained high in Cheshire and Buxton, but in others, removal decreased. In the Stockbridge soil formed on Mg-rich dolomitic glacial till, the leachate was rich in Mg. Earlier, electron microprobe analysis of thin sections of soils indicated that the loci of cesium exchange were heterogeneously distributed in clay varves and coatings and in weathered biotite grains. The microprobe also indicated that weathered biotite grains sorbed as much Ca per unit volume as clay.

2.0989, OXYGEN STATUS OF SOIL AIR AND SOIL WATER AS INFLUENCED BY OXYGEN TRANSFER THROUGH THE SOIL PROFILE

R.W. WENGEL, Univ. of Connecticut, School of Agriculture, *Storrs, Connecticut* 06268

The purpose of this research will be to investigate and define those factors affecting the diffusion and mass transfer of oxygen through the soil profile with particular emphasis on the resultant oxygen status of water moving laterally or downward toward the ground water system.

The factors to be investigated are: soil air-space porosity distribution over the soil moisture release characteristic, oxygen sink sources within the soil profile and their relative importance in oxygen consumption, and the mass transport of oxygen during infiltration.

Soil porosity and soil water will be determined using standard pressure plate and pressure membrane technique. Gaseous oxygen in the profile will be determined from diffusion chamber samples by gas chromatography. Dissolved oxygen will be determined by polarographic techniques on soil water samples during periods of saturation and by oxygen solubility calculations based on gas-liquid phase equilibria during periods of unsaturation.

The quantitative measurement of oxygen transfer and utilization in soil will have application in studies of: oxidation-reduction reactions in the lower soil profile, potential conditions for biological oxidation of soluble organic contaminants in soil water, and soil oxygen supply characteristics for subsurface oxidation of organic wastes such as those from small septic systems.

2.0990, THREE DIMENSIONAL DISPERSION FROM POINT SOURCES OF CHEMICAL OR THERMAL POLLUTION IN OPEN CHANNELS

M.R. SAMUELS, Univ. of Delaware, School of Engineering, *Newark, Delaware* 19711

The proposed research plan involves an experimental and numerical study of three dimensional dispersion from point sources in open channels.

The experimental studies will include measurement of: 1. Turbulent velocity, intensity and scale measurements, in open rectangular channels: 2. Pollutant (salt) concentration fields as functions of both time and position downstream from the injection of a saline solution into the channel. Both continuous and lumped injections will be studied.

The numerical studies will be centered around development and use of a suitable computational model for describing three-dimensional dispersion of the pollutants introduced at point sources. Once the program is complete the turbulence measurements from the experimental studies will be used to predict (via analogy expressions) turbulent dispersion coefficients. Numerical calculations based on these coefficients will then be compared with the experimental results. If satisfactory agreement is not obtained, then the dispersion coefficients will be varied until reasonable agreement is obtained. The dispersion coefficients so obtained will be correlated against the turbulent properties of the fluid flow.

The sensitivity of the calculated pollutant concentrations to changes in the various dispersion coefficients and velocity profile will also be examined to determine which if any of these terms may be neglected, or simplified in future dispersion models.

2.0991, CORROSION AND ENCRUSTATION MECHANISMS IN WATER SUPPLIES

F.E. CLARKE, U.S. Dept. of the Interior, Geological Survey, *Washington, District of Columbia* 20242

A variety of physical, chemical, and biological processes determine tendencies of water supplies to cause objectionable corrosion problems in wells and other water handling equipment. Knowledge of these mechanisms is necessary for proper prediction of effects and proper control. Quality characteristics of well water supplies are determined by field studies and the data are analyzed thermodynamically for evidence of potential encrustation and corrosion reactions. The work to date in deep well fields of Egypt, Nigeria, and West Pakistan has revealed that the oxidation reduction potential - pH relationship - is very important in determining magnitude of corrosion damage. Chemical equilibrium studies appear to indicate that degree of saturation with calcium carbonate and ferric hydroxide are major factors in determining the nature and intensity of corrosion. Encrustation with ferrous carbonate, a common problem, appears to be independent of the concentration of this mineral in the well water and to depend primarily on kinetic factors, such as flow rate. Effective control measures are being devised on the basis of these studies.

2.0992, EVALUATION OF C-14 DATING OF GROUND WATER

B.B. HANSHAW, U.S. Dept. of the Interior, Geological Survey, *Washington, District of Columbia* 20242

Technical objective: To improve the method of carbon-14 dating of ground water and to evaluate its application in a wide range of geochemical systems. The Army has direct interest in water contamination problems in the field by radioactive matter and the field disposal of radioactive wastes. To make practical solutions possible, it is necessary to be able to determine the age of ground water. The age indicates the degree of mobility of such water from high mobility to near-immobility. Therefore, it has a direct bearing upon the problem of quickly finding water-bearing layers (aquifers) at depths not easily and quickly contaminated by atomic warfare. The techniques of C-14 dating which have been developed are also relevant to Army studies of glacier ice in Greenland and the Antarctic.

SUPPORTED BY U.S. Dept. of Defense - Army

2.0993, DISSIPATION AND DIFFUSION OF HEAT IN STREAMS AND LAKES

N. YOTSUKURA, U.S. Dept. of the Interior, Geological Survey, *Washington, District of Columbia* 20242

Purpose: To develop a method for prediction of the temperature variation in streams and lakes which are subjected to thermal loading.

2. WATER QUALITY

Methods: The energy budget method of temperature prediction assumes uniform distribution of heat within a cross section of a flowing water and accounts for heat exchanges at the boundaries of the water body. It has been indicated theoretically that inclusion of longitudinal dispersion coefficients in a heat balance equation would materially affect the distribution of temperature along the length of a stream. This project will initially emphasize a basic study of the effect of heat diffusion or of non-uniform distribution of heat within the body of water on the ultimate dissipation of heat. The effect of stratification of flows, especially in estuaries, on heat dissipation will also be investigated.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0994, LAND DISPOSAL OF DAIRY FARM WASTE
A.R. OVERMAN, Univ. of Florida, School of Agriculture, *Gainesville, Florida* 32601

The proposed research seeks to determine feasible loading rates of dairy waste on sandy soils to avoid pollution of underground water supplies. Field studies on the fate of nitrogen and phosphorus will be conducted. Manure slurry from the milking barn will be applied at various rates by sprinkler irrigation. Chemical and physical analysis will be carried out to determine nutrient movement through the soil profile.

Chemical measurements would include: 1. COD (Chemical Oxygen Demand). 2. BOD (biochemical oxygen demand). 3. Total N, NO-3, and NH 4 plus. 4. Total P and orthophosphate. 5. CU, Mn, Ni, Mg, Zn and B. 6. pH. 7. Organic matter in soil. Physical measurements would include: 1. Water - holding capacity of soil. 2. Hydraulic conductivity. 3. Application rates of slurry. 4. Ground water table. 5. Surface runoff.

Correlations are to be obtained between nutrient input, percolation losses, storage in the soils, and uptake by plants growing in the soil.

2.0995, AEROBIC, HETEROTROPIC BACTERIA IN ESTUARIES
M.E. TYLER, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-BC-01429)

OBJECTIVE: Characterize, systematically, the major bacterial types in estuaries, with particular attention to their biochemical activities and potential roles in turnover of organic matter.

APPROACH: About 60 characters of each of 2000 isolates from an unpolluted and a polluted estuary have been determined; nearly 500 pure cultures are maintained. Major taxa will be discriminated among the 2000 isolates by numerical taxonomy. About 150 features of each of the nearly 500 isolates will be determined, including the mole-ratio of guanine and cytosine in DNA; these data will permit speciation by conventional and taxonometric methods. Attempts will be made to assess potentials for organic turnover by, e.g., measuring turnover of fatty acids and ATP.

PROGRESS: Two groups of estuarine bacteria have been characterized by morphology, physiology, and DNA base-ratio. One group of nine isolates constitutes a previously undescribed species of the genus Vibrio, producing an indigoidin-like pigment. The other group is difficult to place taxonomically: the isolates produce violacein, like Chromobacterium, but resemble Vibrio in several characteristics, including DNA base ratio. One anaerobic, methanogenic isolate from the Waccasassa estuary has been purified and characterized, and two other isolates are being processed.

2.0996, USE OF THE BOULDER ZONE FOR WATER STORAGE AND/OR FOR WASTE DISPOSAL
R.O. VERNON, State Bur. of Geology, *Tallahassee, Florida* 32302

Approximately along the contact of the fresh water with the salt water of the Floridan artesian aquifer there occurs an extremely pervious zone which the well drillers have called the 'Boulder Zone'. This zone apparently represents some subsurface formation that has been easily dissolved and has been removed. Or it represents a solution zone that has formed along the contact of fresh and salt water in the artesian system. The dynamics of this flow are not fully understood and it is hoped that further study of the zone, both the hydrology and the geology will provide sufficient knowledge to allow its safe usage for storage of fresh water in the distal end of Florida where the artesian water is brackish or to use this zone for waste disposal after the waste has been treated to some extent and reduced to sludges.

SUPPORTED BY Florida State Government - Tallahassee

2.0997, STUDIES ON SOUTHEASTERN AQUATIC INSECTS
J.B. WALLACE, Univ. of Georgia, School of Agriculture, *Athens, Georgia* 30601

The overall objective will be to develop a background of knowledge in the scientific literature that will permit identification of the aquatic insect species of the southeast as they are influenced by and relate to water quality. The basic objective is to provide adequate species characterization of the immature stages. The order Trichoptera will receive most attention during the initial phases of the study with additional information gathered on the orders Ephemeroptera and Plecoptera. Field collecting will be followed by laboratory and field rearing in order to associate juvenile forms with proper adult species. Ecological and water quality parameters will be assembled for individual species during this study. The role of aquatic insects in breaking down detritus is also being evaluated.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0998, CHARACTERIZATION OF STREAM REAERATION CAPACITY
E.C. TSIVOGLOU, Georgia Inst. of Technology, School of Civil Engineering, *Atlanta, Georgia* 30332

The broad objective of this reseach is to fully develop techniques for the accurate evaluation of waste treatment needs and associated costs in specific situations, as currently used procedures are not adequate. The principal source of difficulty and large error has been our inability to accurately evaluate the reaeration capacity of natural streams. Research begun by the Administration three years ago has been successful in providing a direct field technique for the accurate determination of stream reaeration capacity. This technique now forms the necessary basis for providing water pollution control agencies and industry with the means for accurate evaluation of and prediction of waste treatment requirements and costs.

The specific objectives of this research, briefly stated, are to apply the gaseous tracer method developed by the Administration to: evaluate the range of error normally associated with the various available mathematical models for predicting reaeration capacity (O'Connor-Dobbins, Churchill, etc.); on the basis of direct field observations of reaeration capacity, to develop the necessary modified and/or additional models for this purpose; and, to develop a standardized laboratory procedure for evaluating the effects of various kinds of water pollutant on the reaeration capacity of river water.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.0999, SYMPOSIUM PRESENTATION OF RESEARCH FINDINGS ON THE REAERATION CAPACITY OF STREAMS AND ESTUARIES
E.C. TSIVOGLOU, Georgia Inst. of Technology, School of Civil Engineering, *Atlanta, Georgia* 30332

This symposium is to present results of current research in the area of application of radioactive tracer techniques to gas transfer kinetics, in particular measurement of reaeration of natural streams. National interest in the results of this research on the reaeration capacity of natural streams is very high, as evidenced by numerous requests for information and studies elsewhere, both in natural streams and in estuaries. Interest has been shown not only in the direct measurement of reaeration capacity, but also in the derivation of information regarding mixing and dispersion

characteristics of such natural water courses. The importance of oxygen transfer in pollution control and abatement is such that immediate dissemination of the results of these studies is recommended. The presentation will include experimental techniques, results from several rivers, and a field demonstration of the tracer technique on a local stream.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1000, ESTUARINE HYDROGRAPHY AND ITS ROLE IN TRANSPORT OF NATURALLY PRODUCED FOODS AND POLLUTANTS

F.C. MARLAND, Univ. of Georgia, Marine Institute, *Sapelo Island, Georgia* 31327

The major objective of the program is to conduct a hydrographic study of the three representative types of estuaries that are found in Georgia. The estuaries of Georgia, as well as those of the entire United States, are being destroyed at an accelerated rate. Research is needed to provide basic information concerning estuaries to serve as a guide in formulation of The National Estuary Policy. Through studies of; (1) water mass movements, (2) seasonal temperature, salinity and oxygen patterns, (4) seasonal import of organic/inorganic materials, and (5) seasonal current patterns, a better understanding of the role of hydrographic factors in the distribution of nutrients and pollutants into and throughout the estuaries.

The estuaries of Georgia exist in a relatively undisturbed condition. This study will provide basic information concerning the conditions that are fairly close to the natural state before man-made manipulations occur, and may thus explain some of the causes of the high productive capacity of estuaries. With increases in population and industry the estuaries will be subject to greater pollution pressure. The hydrographic characteristics of estuaries must be known and understood in order to predict the amounts and kinds of effluents that estuaries can receive and their ultimate distribution after entry.

2.1001, TERRESTRIAL ECOLOGY

J. KLINE, Argonne National Laboratory, *Argonne, Illinois* 60439
(W-31-109-ENG-38)

Tritium Studies. The objective of the tritium studies is to analyze the physical and biological behavior of tritium upon release in a terrestrial environment. Physical and biological studies are carried out simultaneously with the intention of developing a multi-compartment model for tritium dynamics in an ecological system. Physical studies are devoted largely to behavior of tritiated water in soils of a grassland. Injections and surface spray applications of tritiated water are utilized to determine rates of flow of tritiated water, distribution of soils and mean residence times in soils. Mass flow of soil water is monitored using lysimeters placed at several different depths in the soil as water collectors. Biological tritium studies are devoted to field work on the use of tritiated water to measure transpiration by trees and to laboratory work on the incorporation of tritium into the organisms from a tritiated water source. The transpiration studies in trees are carried out by injecting tree trunks with tritiated water and sampling the foliage until all the tritium has passed through the tree. In the lab studies, algae are being grown in tritiated water to determine rates and amounts of incorporation of tritium into organic molecules.

Results: Onset of transpiration in the spring in pine trees was correlated with soil temperatures. Transpiration did not begin until the soil was completely thawed even though free water was available both above and below the final lens of frozen soil which occurred at 10 centimeters depth. No evidence of winter transpiration was found in trees which had received winter injections of tritiated water. Algae grown in tritiate water show an apparent deficiency in tissue bound tritium. The tritium-hydrogen ratio of algae tissue has consistently been about 30% less than the ratio of aqueous growth medium.

2.1002, COOLING TOWER STUDY

E. AYNSLEY, IIT Research Institute, *Chicago, Illinois* 60616

A recently initiated study of water cooling towers is aimed at outlining and assessing related environmental effects, particularly with reference to natural draft units. Natural draft cooling towers are becoming increasingly popular throughout the United States in attempts to alleviate problems associated with limited availability of cooling water supplies, thermal pollution problems and legislation limiting disposal of thermal wastes.

Inadvertent weather modifications such as fogging, cloud initiation and formation which result from tower emissions of water vapor and heat will be considered. Already there have been reported fogs of increased frequency and density which are attributed to cooling tower operations. Interaction of cooling tower plumes with other nearby stack plumes will be investigated particularly in the context of SO2 oxidation. Other aspects include a theoretical description of heat and water vapor diffusion in the plume and droplet carryover of recirculating water.

A survey of all natural draft towers currently operating and planned in the United States will be included.

2.1003, A CRITICAL TEST OF METHODS FOR ISOLATION OF VIRUSES FOR USE IN CONTROL OF NUISANCE ALGAE

H.N. GUTTMAN, Univ. of Illinois, School of Liberal Arts, *Chicago, Illinois* 60680

First tests by others have revealed the presence of a very few types of algae viruses which are now being tested as potential controllers of nuisance algae. The methods for virus selection selects against isolation of the rarer viruses which may be more valuable because of different host specificity, etc.

We are therefore critically evaluating two methods for isolation and purification of algal viruses to determine whether the commonly used method inadvertently selected out for the few most abundant viruses and against the rarer viruses which may have more eventual value as algal controllers.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1004, DISPERSION OF CONTAMINANTS IN JOINTED ROCK

R.J. KRIZEK, Northwestern University, School of Technology, *Evanston, Illinois* 60201

Deep injection wells into jointed rock strata provide one of the promising methods for the disposal of certain liquid wastes. However, relatively little is known about the characteristics of flow behavior in jointed rock. From a water resources point of view, such knowledge is very valuable when appraising the long-term quality of water from a jointed rock aquifer. Accordingly, the objectives of this research are (1) to formulate a basic seepage law for the flow of a homogeneous fluid through jointed rock, and (2) to develop a theoretical model for the dispersion of a miscible contaminant into a homogeneous parent fluid which saturates a jointed rock stratum.

The investigation will be both theoretical and experimental in nature, and emphasis will be placed on plane and axi-symmetric artesian flow under steady conditions. The entire practical range of Reynolds numbers will be investigated both for uniform seepage flow and for dispersion. The experimental model will consist of an orderly array of impermeable prismatic blocks separated by relatively narrow flow channels which will intersect at various angles. Concurrent with the development of an experimental flow law for this system, a theoretical analysis, based on a finite difference solution of the Navier- Stokes equations, will be performed. Hopefully, the synthesis of the experimental and theoretical results will lead to the development of a model which will have broader application to more complex systems.

2. WATER QUALITY

SUPPORTED BY University of Illinois

2.1005, ECOLOGY OF SPHAEROTILUS IN ACTIVATED SLUDGE
W.O. PIPES, Northwestern University, School of Technology, *Evanston, Illinois* 60201

This project is a survey of activated sludge plants to determine 1) what types of filamentous organisms are present when the sludge has poor compaction characteristics, 2) the extent to which the compaction characteristics of the sludge depends upon the presence of filamentous organisms, and 3) environmental factors which encourage the growth of filamentous organisms in activated sludge. The research plan consists of collecting samples of sludge from a number of activated sludge plants; physical, chemical, and biological analyses of the sludge samples; and statistical analysis of the data to find correlations between the various parameters. Loss of sludge in the effluent due to poor compaction in the secondary settling tank or for other reasons is the most common operating problem with the activated sludge process and delineation of the factors which contribute to this condition should result in significant improvements in process operation.

2.1006, INVESTIGATION OF PERMEABILITY OF FINE GRAINED GLACIAL SEDIMENTS IN RELATION TO WASTE DISPOSAL IN ILLINOIS
R.E. BERGSTROM, State Geol. Survey, *Urbana, Illinois* 61801

The objective of the research is to evalute current methods and to develop practical procedures for determining the field permeability of fine grained glacial sediments. These sediments -- mainly tills -- are too tight to be analyzed for permeability on the basis of conventional pumping tests. Field measurements will be made using several methods of injection -- and possibly pumping -- in shallow bore holes. Laboratory tests will be made on cores by standard permeameter methods.

The permeability data will be obtained from representative glacial deposits of known character and extent, so that results may be extrapolated, and will be evaluated for such practical applications as selecting sites for surface waste disposal, protecting shallow aquifers from pollution, and appraising drainage and ground-water recharge conditions.

Illinois State Geological Survey review, June 1970: Project continuing in FY 1971.

SUPPORTED BY Illinois State Government - Springfield

2.1007, HYDROGEOLOGY OF SOLID WASTE DISPOSAL SITES
G.M. HUGHES, State Geol. Survey, *Urbana, Illinois* 61801

The objectives of this project are to investigate, in northeastern Illinois, hydrogeologic environments which are currently being used for shallow solid waste disposal, and to evaluate the factors which control ground-water movement of refuse leachate in these environments. Criteria are sought to judge the suitability of proposed disposal sites not only in glaciated areas, such as northeastern Illinois, but in many other areas as well.

Existing landfills are being studied, and the investigation is proceeding by: (a) drilling by wash boring or with hollow stem augers to determine the character and sequence of deposits, (b) installation of piezometers to define fluid potential distribution and the ground-water flow system, (c) sampling of the ground water for chemical analysis, (d) a monitoring program of the piezometers to determine seasonal variations of the flow system.

Illinois State Geological Survey review, June 1970: Project completed - final report on project to be published in FY 1971.

SUPPORTED BY Illinois State Government - Springfield

2.1008, ASSIMILATION OF A WASTE TREATMENT PLANT EFFLUENT BY A CREEK-RIVER-MAINSTREAM IMPOUNDMENT SYSTEM
R.W. LARIMORE, State Natural History Survey, *Urbana, Illinois* 61801

The purpose of this study is to investigate the assimilation of a waste treatment plant effluent by a creek-river-mainstream impoundment system. Various physical, chemical, and biological measurements will be used in this investigation. Areas of intensive study include (1) tracer studies to determine the transport and dispersal of pollute within the system, (2) measurements of the biota within the area affected by pollutant material, (3) measurements of the assimilation of the pollutes by the system, (4) measurements of primary productivity and fish production, and (5) the effects of the treatment plant effluent upon this production. Information obtained here may be useful in indicating a means of managing reservoir productivity through controlled introductions of nutrient material from the waste treatment plant.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1009, EFFECTS OF CONTAMINANTS ON REAERATION
Y. KOTHANDARAMAN, State Water Survey, *Urbana, Illinois* 61801

The water quality aspects of a well-conceived water resources management plan require an accurate knowledge of the rates of atmospheric reaeration. Insight into the interrelationships of stream impurities, DO saturation values, and rates of reaeration will greatly aid in assessing more precisely a stream's capacity to assimilate waste.

An investigation is in progress on Illinois River water to: 1) investigate the extent of variation in DO saturation values at 20C due to changes in the concentration of contaminants in the water and 2) delineate the effects of the constituent contaminants in natural water on the reaeration rate constant, K2. Each river sample is analyzed for suspended solids, dissolved solids, chemical oxygen demand (as a measure of organic impurities), and surface active agents. These are the classes of impurities found to have a significant effect upon atmospheric reaeration rates.

SUPPORTED BY Illinois State Government - Springfield

2.1010, BOUNDARY EFFECTS ON JET FLOW PATTERNS RELATED TO WATER QUALITY AND POLLUTION PROBLEMS
W.H. MAXWELL, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

This experimental program will be divided into two phases: (1) Collection and analysis of further experimental data on velocity distributions downstream from a water jet introduced horizontally beneath the free surface of a deep reservoir. (See Project A-010-111). The diameter of the jet, submergence of the jet and velocity of efflux from the jet will be varied systematically to determine their influence on the flow pattern. (2) Velocity traverses will be taken of the flow field downstream from a water jet introduced horizontally beneath the free surface of a shallow reservoir. The diameter and submergence of the jet, velocity of efflux and the vertical location and slope of the lower fixed boundary will be varied systematically.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1011, METHODOLOGY FOR SYNTHESIS AND OPTIMIZATION OF DIFFUSION PATTERNS IN FLOW SYSTEMS
W.H. MAXWELL, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

The influence of non-uniformity of velocity distributions in natural flow systems on the diffusion of tracers, pollutants, etc., requires clarification.

The objectives are to synthesize non-uniform flows using distributions of infinitestimal point source jets of different strengths to represent the momentum, heat or mass flux. Sources of pollution or tracer may then be readily combined with the ambient distribution to predict the diffusion pattern. Orientation and location of injection sources will be varied to determine the most practically desirable diffusion pattern for different objectives. If the technique proves successful it will provide a single solution for a given flow without the necessity of matching two approximate solutions downstream from the point of injection.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1012, HYDRAULIC GEOMETRY AND LOW STREAM-FLOW REGIMEN
J.B. STALL, Univ. of Illinois, State Water Survey Division, *Urbana, Illinois* 61802

A completed project shows there to be, for the 18 river basins in Illinois, a consistent pattern in which the width, depth, and velocity of flow in a stream change along the course of the stream, with a constant frequency of discharge. These channel characteristics are termed Hydraulic Geometry and constitute an interdependent system which can be described by a series of graphs having simple form, or by equations. Relations are strongest at high and medium flows.

These results have been used to compute provisional time-of-travel for 46 major stream reaches in Illinois. The results seem adequate at high and medium flows, but only fair at low flows. The proposed research would characterize and evaluate the complex flow regimen at low stream- flows in selected stream reaches, and check computed times-of- travel by using dye tracer measurements. Dispersion in the stream will be evaluated also. The results can potentially be generalized throughout the stream system to allow prediction of the assimilative capacity of the stream and dispersion of a contaminant.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1013, MINIMIZING NITRATE POLLUTION OF GROUNDWATER AND STREAMS
S.A. BARBER, Purdue University, School of Agriculture, *Lafayette, Indiana* 47907

The aim of this project is to characterize the reason for the inability of the plant root to remove a higher proportion of the nitrates from the soil water. Nitrates move to the root primarily by mass-flow since they are transported to the root in the water used in transpiration. Because of this it should be possible for the crop to absorb a large proportion of the nitrate from the soil water. The ability of various types of roots to absorb nitrates from water will be examined. The results of these investigations will be used to formulate procedures that can be used to reduce the nitrate level of soil water.

The specific objectives of this research are: 1. To determine the principles involved in the absorption by plant roots of nitrate from water in the soil profile. 2. To develop water, soil, crop, and fertilizer management procedures that will minimize the movement of nitrate down the soil profile in percolating water.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1014, DISPERSION DURING FLOW IN HETEROGENEOUS POROUS MEDIA
R.A. GREENKORN, Purdue University, School of Chemical Engineering, *Lafayette, Indiana* 47907

The immediate objective of this project is to study the theory and measurement of dispersion in heterogeneous anisotropic porous media. A better understanding of dispersion phenomena is necessary to obtain useful flow models of real porous media. Initially, we will study the differential equations associated with dispersion. Present statistical models will be extended to include heterogeneity and anisotropy. Dispersion coefficients will be measured in linear and radial flow in heterogeneous anisotropic media using tracer techniques and these data will be used to determine the statistical range of the dispersion coefficient in view of microscopic and macroscopic heterogeneity, fluid properties, and anisotropy. A better understanding of the fundamental nature and description of disperson will allow better calculation of miscible flow in porous media. This study of effects of heterogeneity and anisotropy on disperson has immediate practical application: in tracing seepage of contaminates into underground fresh water; in reclamation of waste water; in underground disposal of chemical, bacterial, and radioactive wastes; in ion exchange; in filtration theory; in the movement of fluids in the human body; and in the flooding of oil reservoirs.

2.1015, IMPROVING THE QUALITY OF OUR WATER RESOURCES
E.J. MONKE, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01460)

OBJECTIVE: Study the dynamics of water and pollutant movement in unsaturated soil. Study the role of plants in water quality management. Evaluate treatment of polluted water by filtration through the soil mantle.

APPROACH: The basic approach is to simulate the dynamics of pollutant-laden moisture through the natural filter composed of soil, plants, and many forms of bacteriological life for use in the design of engineering systems for water quality control. Research will be done mainly under controlled environmental conditions in the laboratory with occasional pilot studies being performed at the Southern Indiana Forage Farm.

PROGRESS: An analysis of infiltration equations was made on the basis of experimental data obtained in erosion studies with a plot-sized rain-fall simulator. An overland flow analysis was used to determine infiltration-time relationships from runoff hydrographs. Regression fits of the 4 equations to experimental data for 52 tests on 13 soils showed that all of the equations adequately described infiltration phenomenon. Difficulty of applying any of these equations is in evaluating equation parameters. An approximate method for defining conductivity function of unsaturated soils was developed. Method utilizes the water retention curve and the influx-time relationship for infiltration into an initially dry soil column to determine the effective conductivity function. Tests have shown the procedure gives results which closely approximate the original conductivity data. Measurements required in the proposed method can be made in a relatively short time. It can be adapted also for in-place, field determinations of unsaturated conductivities. This procedure along with further refinements in numerical techniques and computing hardware which are bound to come about can make the solution of the 'exact' governing equation a practical means for quantifying infiltration on a field scale.

2.1016, DENITRIFICATION AS A PATHWAY FOR NITRATE REMOVAL IN RIVERS AND PONDS
D.W. NELSON, Purdue University, School of Agriculture, *Lafayette, Indiana* 47907

Denitrification has been shown to occur in soils and solution cultures, and there is recent evidence to indicate that denitrification will occur in surface waters and may be an important natural pathway for the removal of nitrate from rivers and ponds. The following objectives have been established for this study: 1. To determine the rate of denitrification occurring in river and pond waters which have widely different nitrate loading rates, dissolved oxygen concentrations, soluble organic carbon contents, and microbial populations. 2. To determine the potential denitrifying capacities of river and pond waters which vary widely in dissolved oxygen content, microbial population, and other factors which influence microbial activity. 3. To determine the effect of environmental factors such as temperature, pH, soluble organic carbon content, and dissolved oxygen concentration on the rate of denitrification in river and pond waters.

2.1017, USING SOIL FILTRATION TO REDUCE POLLUTION POTENTIAL OF LAGOON EFFLUENT ENTERING GROUND WATER SYSTEM
C.E. BEER, Iowa State University, School of Agriculture, *Ames, Iowa* 50010

The practice of disposal of animal manure and collection of feedlot runoff in lagoons is being widely used. In most cases Pollution Control Commissions will not permit the direct release of lagoon effluent into surface water streams.

The objectives of this research are to develop land application criteria for the lagoon effluent whereby the quality will be such that pollution potential will be minimal, and the effluent may

enter the ground water system. The change in the soil structure, soil chemistry and biological environment will be also studied.

The experimental procedure will involve the sprinkling of lagoon effluent (swine wastes) at controlled rates and frequencies on the experimental area. A tile network will intercept the effluent after infiltration and filtering through the soil and permit the change in quality of the effluent to be evaluated. The soil samples to be studied will be taken directly from the experimental areas.

2.1018, EFFECTS OF LIMNOLOGICAL FACTORS ON WATER TREATMENT

D.B. MCDONALD, Univ. of Iowa, School of Engineering, *Iowa City, Iowa* 52240

Limnological studies of the Coralville Reservoir, Johnson County, Iowa, and the Iowa River above and below the impoundment are currently being conducted. Additional studies of the reservoir and river will be conducted under the proposed project to determine the effects of various chemical and biological conditions within the reservoir and the river on the quality of water utilized by the University of Iowa Water Treatment plant, located on the Iowa River about five miles below the Coralville Dam. In-plant studies, involving modification of treatment methods, chemicals used, points of application of chemicals and rates of treatment, will be conducted to determine the best treatment methods under varying conditions of water quality.

2.1019, RESEARCH INITIATION - MIXING AND TRANSFER PROCESSES FOR HEATED EFFLUENTS IN OPEN CHANNEL FLOW

W.W. SAYRE, Univ. of Iowa, School of Engineering, *Iowa City, Iowa* 52240

The discharge of large quantities of waste heat into streams and rivers has become a subject of increasing concern in recent years. To assess beforehand what the probable effects will be, environmental engineers should be able to predict the downstream temperature changes resulting from a given combination of effluent temperature and discharge, source configuration, and streamflow conditions.

The principal aim of the research proposed herein is to obtain a better understanding of the processes by which the effluent heated water mixes with the flowing streamwater and the excess heat is transferred to the surrounding phases of the environment, and furthermore, how these processes combine to produce the resulting temperature distribution pattern in the stream. These phenomena would be investigated in a controlled temperature system, consisting of a recirculating flume housed in a controlled environment chamber, wherein the temperatures of the flume water, the flume boundary and the air can be controlled independently.

The experimental data would be analyzed with a view toward obtaining longitudinal, transverse and vertical mixing coefficients as well as heat transfer coefficients for the water surface and channel perimeter. Functions which relate these coefficients to known streamflow, effluent and channel properties, and other pertinent environmental conditions, would be sought.

SUPPORTED BY U.S. National Science Foundation

2.1020, NATURAL MIXING AND TRANSFER PROCESSES FOR THERMAL LOADS IN STREAMS

W.W SAYRE, Univ. of Iowa, School of Engineering, *Iowa City, Iowa* 52240

The principal aim of the proposed research is to obtain a better understanding of the natural processes in streams and rivers by which effluent heated water mixes with the flowing streamwater and the excess heat is transferred to the surrounding phases of the environment, and furthermore, how these processes combine to produce the resulting temperature distribution pattern in the stream. These phenomena would be investigated in a controlled temperature system, consisting of a recirculating flume housed in a controlled environment chamber, wherein the temperatures of the flume water, the flume boundary and the air can be controlled independently.

The experimental data would be analyzed with a view toward obtaining longitudinal, transverse and vertical mixing coefficients as well as heat transfer coefficients for the water surface and channel perimeter. Functions which relate these coefficients to known streamflow, effluent and channel properties, and other pertinent environmental conditions, would be sought.

Finally, the investigation would be directed toward the development of mathematical predictors for temperature distribution patterns resulting from various combinations of effluent temperature and discharge, source configuration, streamflow and other environmental conditions.

2.1021, DISPERSION OF WATER POLLUTANTS IN CURVILINEAR FLOWS

W.W. SAYRE, Univ. of Iowa, School of Engineering, *Iowa City, Iowa* 52240

In a sinuous channel with successive bends representing river meanders, which was specially built for this project, the dispersion of simulated pollutants is studied experimentally. Velocity and conductivity probes developed for this project are used to determine the flow characteristics and the concentration of the pollutant simulator. Experiments in a smaller channel are performed to gain knowledge about dispersion when there is a density bias. In addition to the experimental study, analyses are being developed with the purpose of interpreting the experimental results and of achieving methods of predicting dispersion of pollutants in water streams. A Ph.D. dissertation has been completed recently by Mr. Fukuoka, and is now available on loan from the Institute of Hydraulic Research.

2.1022, REMOVAL OF SUSPENDED MATTER AND TURBIDITY FROM WATER BY FLOCCULATION

V.L. HAUSER, Technion, *Haifa, Israel* (A10-SWC-25)

OBJECTIVE: Determine electrokinetic properties of suspended particles, the reactions occurring when suspended in saline waters and flocculation effects of additive coagulant materials.

APPROACH: Preliminary tests will determine settling characteristics of suspended matter in natural flood water and changes brought about by additions of commercially available polyelectrolytes and other flocculant aids. Electrochemical and other properties of the suspended material will be determined as flocculants are added. Reaction of the suspended materials in waters of various salt concentrations will be studied. Field application studies will also be developed.

PROGRESS: The study showed that water-soluble polymers can be used as primary flocculants for clarification of dilute clay suspensions typical of surface runoff water. Required doses are much lower than those of conventional flocculants, such as alum. Large, fast settling and shear-resistant flocs are obtained by the use of polymeric flocculants, as contrasted to small, slow-settling flocs that result from the use of alum. Organic matter in the water increases the colloidal stability of the dispersed clay. The required doses of flocculating agents are considerably higher as a result of chemical reactions taking place between the organic substances and the flocculant. The organic substances compete with the clay minerals in their interaction with the cationic polymer and, therefore, the removal of mineral turbidity is delayed until the organics have reacted with the flocculant.

SUPPORTED BY U.S. Dept. of Agriculture

2.1023, WATER CLARIFICATION FOR GROUND WATER RECHARGE

V.L. HAUSER, Technion Res. & Develop. Fdn., *Haifa, Israel* (A10-SWC-80)

OBJECTIVE: Remove suspended solids and turbidity from muddy runoff water with polyelectrolytes and/or other chemicals.

Study basic chemistry of solids removal, chemical and organic interference, and biological processes.

APPROACH: Basic physics and chemistry of flocculation of suspensions with polyelectrolytes and hydrolysing flocculant combinations will be studied including the effect of organic matter. Effect on bacterial quality will be investigated with the coliform group of bacteria. An experimental pilot plant will be used to study real systems.

PROGRESS: Methods for flocculating suspended materials in the presence of organic matter have been investigated. Colloidal dispersions of clay turbidity and organic matter with varying degrees of clay-organic interactions were treated with alum and polymeric flocculants. Treatment effectiveness was correlated to organic matter content and clay-organic interaction. A continuous flow pilot water treatment plant was designed and is being installed. It consists of flocculation and sedimentation units. Effects of polymeric flocculants on flocculation kinetics in continuous flow will be studied. Transport of particulates through porous media in relation to filtration is being investigated. From experiments on laboratory sand filters, preliminary data have been obtained on contract coagulation-filtration on sand using hydrolytic and polymeric flocculants. Larger filtration units were designed, and a program was developed to study clogging and particulate transport at filtration rates representing recharge and sand filters. Treatment effects on filtration will be studied and attempts made to relate findings to field conditions in Bushland, Texas.

SUPPORTED BY U.S. Dept. of Agriculture

2.1024, OXYGEN CONSUMPTION IN CONTINUOUS BIOLOGICAL CULTURE

W.J. OBRIEN, Univ. of Kansas, School of Engineering, *Lawrence, Kansas* 66044

The objectives of this research are to measure the rate of oxygen consumption of nutrient limited, completely mixed, activated sludge systems and to utilize these measurements to develop a theoretical basis for the response of these systems to abrupt changes in the influent nutrient concentration.

Hydraulic means residence times in the aeration basin of from three to twenty-four hours are being investigated. Both aeration only and aeration with sludge return systems will be considered.

Preliminary results indicate the existence of a peak rate of oxygen consumption during transition growth periods following an increase in the influent nutrient concentration in aeration only systems. This peak will be of critical importance in establishing aeration design criteria for the recently proposed plants using biological compartmentalization of the influent nutrient followed by chemical flocculation to remove the micro-organisms from solution.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1025, DISPOSAL OF HEATED WATER THROUGH GROUND WATER SYSTEMS

G.P. WILLHITE, Univ. of Kansas, School of Engineering, *Lawrence, Kansas* 66044

This proposal seeks to evaluate the technical and economic feasibility of using a ground water system, hydraulically connected to a larger body of water, as a means of introducing waste heat into the larger body. In the proposed process hot water would be injected into the ground water system through wells, entering the larger body at numerous points along the sides and bottom. Some of the heat would be dissipated by conduction to the underlying and overlying strata. The remainder would be dispersed in the large body of water as the heated water rises due to density differences.

The proposed project has two phases. Stage I will determine the conditions under which the process can be used to introduce heated water into the larger body of water when the temperature of the larger body remains within thermal pollution limits. Scaled laboratory and mathematical models of the process will be developed for a river system. Process parameters obtained in Stage I will be used to develop the economics of disposing of heat in the Kansas or Missouri Rivers in Stage II.

2.1026, GROUND WATER RECHARGE THROUGH PITS AND WELLS

H.L. MANGES, Kansas State University, School of Engineering, *Manhattan, Kansas* 66502

Irrigation development increases the drainage problem in areas with poor natural surface drainage. An alternative to an organized Drainage District is to dispose of excess water by recharge into the underground aquifer. This can be accomplished by pits or wells if suspended material is removed from the surface water.

A series of recharge pits will be dug to the top of the underground aquifer. The pits will be backfilled with a filter material. Various materials, including fiberglass, sands and gravels, will be evaluated in the laboratory before selecting a filter design for field trials.

Underground draintile will be installed to determine if the natural soil profile can be used as an effective filter for removing suspended particles from surface runoff water. Runoff from rainfall and irrigation will be diverted onto the area and the flow rate and amount of suspended sediment determined.

The potential recharge rate of a selected aquifer will be determined. Water will be pumped from an existing irrigation well into a recharge well.

The work will be accomplished at Kansas State University, Manhattan, and the Sandyland Irrigation Field at St. John, Kansas.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1027, PRE AND POST-IMPROVEMENT LIMNOLOGICAL ANALYSES AND FISH POPULATION EVALUATIONS OF CERTAIN STRIP-MINE LAKES IN SE KANSAS

C. BASS, State Forest. Fish & Game Com., *Pratt, Kansas* 67124

Objective: To conduct pre- and post-improvement analyses of the limnological conditions of strip-mine lakes in Cherokee and Crawford Countries, Kansas. To establish and monitor fish populations and neutralized and previously acid strip mine lakes in Cherokee and Crawford Counties, Kansas. be made with eckman Zeromatic II glass electrode pH meter. b. Turbidity to be determined by the use of standard 20 cm diameter Secchi plate. c. Dissolved oxygen is to be determined by one of two techniques; (1) the sample- blank modification of the basic Winkler method, or (2) Beckman Model 707 Dissolved Oxygen Analyzer. d. Ortho- and meta-phosphates to be determined by methods outlined by Hach. e. Nitrate concentrations to be determined by a modification of the brucine-sulfate sulfinilic acid test outlined by the APHA (1965). f. Carbon dioxide determinations to be obtained mathematically from procedures outlined by Moore (1939). g. Boiling-point acidity determined according to procedures outlined by the APHA (1965). h. Total alkalinity test procedures are those outlined by the APHA Standard Methods (1965). i. Temperatures (air and water) to be determined by direct reading from a Yellow Springs Instrument Co. tele- thermometer. j. Soil-analyses to be made according to techniques proposed by Jackson (1958). k. Determinations of numbers of benthic organisms per square meter of bottom material to be in accordance with procedures outlined by Welch (1948). l. The number of planktonic organisms per liter of original water sample will be determined according to the total-count method outlined by Welch (1948). 2. a. Growth rate and condition will be determined for fish populations established in certain strip-mine lakes, which have previously undergone rehabilitation. b. New populations of fish will be established in certain strip-mine lakes following the neutralization of acid waters by agricultural lime (non- project activities). These populations will be monitored over a period of time, rates of growth checked, and the dynamics of the population- balance investigated ultimately, as a means of determining the feasibility of sustaining such fish populations in previously acid strip-mine lakes.

2. WATER QUALITY

2.1028, THE DIFFUSION COEFFICIENT IN OPEN CHANNEL FLOW
B.J. BARFIELD, Univ. of Kentucky, Graduate School, *Lexington, Kentucky* 40506

The turbulent diffusivity in open channel flow will be investigated as a function of channel roughness, shear velocity, and cross-sectional area. Investigations will be conducted in a research flume using a hot- film anemometer as the basic instrument. Prediction equations will be developed for the turbulent diffusivity as a function of flow parameters and channel parameters. The resulting diffusivity profiles, in conjunction with existing models, will be applicable for predicting the effects of proposed stream modifications on sediment load, predicting the pollution of streams from proposed sewage disposal systems, and for modeling other systems in which diffusion and dispersion are important.

SUPPORTED BY U.S. National Science Foundation

2.1029, THE DISPERSION OF CONTINUOUSLY INJECTED EFFLUENTS IN OPEN CHANNELS
D.P. HARRISON, Louisiana State University, School of Engineering, *Baton Rouge, Louisiana* 70803

The hydrodynamic factors controlling lateral and vertical dispersion of effluents injected continuously into open channels will be studied. Specifically, background information on the dispersion process will be studied, the mathematical description of dispersion will be investigated, and the feasibility of using hydraulic models to develop necessary experimental data will be examined. Further, assuming the feasibility of model studies, experimental plans using hydraulic models at the U.S. Army Engineer Waterways Experiment Station, Vicksburg, Mississippi are to be developed.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1030, RESTORATION DYNAMICS FOR ESTUARIES
K.I. MUMME, Univ. of Maine, School of Technology, *Orono, Maine* 04473

Chemical reactor theory has been applied to the problem of maintaining water quality control of the Penobscot Estuary in Maine. This research will investigate the possibility of operating the 'reactor' (the river) such that the reaction becomes 'runaway' (dissolved oxygen content of the water increases in a runaway manner). It is intended to develop a means of assisting restoration of the river rather than simply controllinng or stopping deterioration of the river.

If the research is successful the river can be considered in either of two ways: active restoration would allow the river to handle even more waste without violating the stream classification; or, the same amount of waste could be discharged into the river but the water could maintain a higher classification than is now possible. This new study will be extended to the entire tidal estuary and the dynamic interaction between the ocean and the river.

SUPPORTED BY U.S. National Science Foundation

2.1031, INDUCED AIR MIXING OF LARGE BODIES OF POLLUTED WATER
S.A. ZIEMINSKI, Univ. of Maine, School of Technology, *Orono, Maine* 04473

The Problem: Organic matter of industrial and natural origins tends to settle on the bottom of lakes and other large water reservoirs where it decays depleting the water of dissolved oxygen necessary to ensure normal aquatic life. Although the upper surface of water which is in direct contact with atmosphere may be saturated with oxygen, the mixing resulting from density differences is too small to replenish the oxygen deficiency in the lower layer. The resulting anaerobic conditions lower the water quality. Formation of hydrogen sulfide as well as sulfides of iron and manganese takes place. The carbon dioxide concentration increases and the pH decreases. This anaerobic decomposition can produce undesirable organics, imparting bad taste, odor and occasionally toxicity to the water. The unoxidized organic matter piles up on the bottom and gradually the body of water becomes smaller and shallower.

Plan of attack: Introduce compressed air in appropriate places of the body of water. The resulting mixing oxygen supply and improved surface aeration will provide the whole body of water the oxygen necessary for bio-oxidation of the waste organic matter. In addition to substantital increase in dissolved oxygen the application of this method results in precipitation of iron, reduction in carbon dioxide content, improvement of color, etc. Although this method has a tremendous potential in decreasing pollution of large bodies of water, very little is known about the various factors affecting the efficiency of the system and therefore its optimum design.

The objective: A mathematical analysis has been conducted in our laboratory which resulted in selection of a mathematical model which correlates the rate of mixing, density differences produced by the induced air, depth of immersion of the aerator, etc. A complete experimental procedure has been worked out to check or modify the model. It is expected that this work will allow a successful and efficient design of induced air systems for different shapes, sizes and depths of large bodies of water.

2.1032, TEST AND EVALUATE EQUIPMENT FOR CONTAINING AND REMOVING OIL SPILLS IN HARBORS AND ADJACENT WATERS
A.E. LANGLOIS, State Port Authority, *Portland, Maine* 04111

Conduct a series of practical tests to evaluate the performance of various equipments for containing and removing spilled oil.

Design and construct a skimming device for removing oil-water mixtures from oil spills. Conduct a desk top study of a complete system for oil skimming, separation and reclamation of spilled oil under varying conditions.

Commercial oil skimmers and/or separators may be tested if available.

Tests will be conducted at various locations in or near the harbor of Portland, Maine. Some tests will be performed at an outdoor laboratory area in South Portland, Maine.

Results of the tests should be valuable to harbormasters and other marine personnel who must contend with oil spills. Results should also indicate specific requirements for improved equipment and optimum methods of using equipment under various conditions.

Field testing is performed by Altenburg, Kirk and Company, an Industrial Research firm in Portland, subcontractors to Maine Port Authority. Close cooperation maintained with civic, marine and Coast Guard organizations in the area. Project was started in August of FY 1968-69 and is scheduled for completion in February of FY 1969-70.

2.1034, NAVY ENVIRONMENT--TURBULENT DIFFUSION AND EXCHANGE PROCESSES IN ESTUARINE, COASTAL AND OCEAN WATERS
A. OKUBO, Johns Hopkins University, Chesapeake Bay Institute, *Annapolis, Maryland* (N00014-67-A-0163-0006)

Technical Objective: The Navy requires a knowledge of diffusion processes in the ocean and the flushing characteristics of

estuarine and coastal areas that may be contaminated by radioactive or dissolved chemical materials emanating from its own or enemy forces. This research is intended to supply basic information for prediction of the dispersion of contaminants through an examination of the theoretical and empirical laws governing the turbulent diffusion of estuarine, coastal and oceanic waters.

SUPPORTED BY U.S. Dept. of Defense - Navy

2.1035, DIFFUSION AND TRANSPORT OF CONTAMINANTS IN TURBULENT SHEAR FLOW
S. CORRSIN, Johns Hopkins University, School of Engineering, *Baltimore, Maryland* 21218 (AT(30-1))

The objective is to try to understand the transport of momentum and the transport of a passive scalar contaminant (such as heat) in a turbulent shear flow. We hope that this will help to establish bases for the estimation of transport rates. We have succeeded in generating a nearly homogeneous turbulent shear flow, and are measuring the statistical properties of the turbulence field, including diffusion of heat from a local source. During the coming year we expect to extend the diffusion experiments to the case of a turbulent boundary layer.

2.1036, PHYSIOLOGY OF ACIDOPHILIC BACTERIA OF ACID MINE WATERS
T.M. COOK, Univ. of Maryland, Graduate School, *College Park, Maryland* 20740

This project consists of a fundamental physiological study of the nature of the acid-resistance and acid-requirement of bacteria associated with acid mine waters. A precise definition of each of these phenomena will be obtained and then an attempt will be made to uncover the mechanisms responsible. The permissible limits of pH for various physiological activities will be determined for the autotrophic ferrobacilli and thiobacilli, as well as a new acidophilic heterotrophic bacterium isolated from acid mine water. A study will be made to determine the relevance of this heterotroph to the management of acid mine water pollution.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1037, DISPOSAL OF WASTES FROM SWINE FEEDING FLOORS TO MINIMIZE STREAM POLLUTION
W.F. SCHWIESOW, Univ. of Maryland, School of Agriculture, *College Park, Maryland* 20742

To investigate methods for disposing of waste from swine feeding facilities. To develop guide lines for design of systems to minimize water pollution by swine wastes.

The present research installation is to be modified and improved to provide data on quantity of waste, characteristic properties of the waste, and performance of the system. Analysis of data obtained from this project is expected to establish guidelines for design of commercially installed systems.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1038, SYSTEM STUDY, DESIGN, AND EVALUATION OF THE LOCAL STORAGE, TREATMENT, AND REUSE OF STORM WATER
C.W. MALLORY, Hittman Associates Inc., *Ellicott City, Maryland* 21043

A comprehensive study was made to determine the economic and technical feasibility of using system for the local storage, treatment, and reuse of storm water as a method of providing pollution control. With this concept, storm water runoff is collected in small reservoirs dispersed throughout urban communities, treated to remove pollutants and is either released to receiving bodies of water or further treated for reuse. The benefits derived from the reuse of storm water are used to offset the cost of pollution control.

As part of this study, a synthesized hydrograph using mathematical expressions derived by regression analysis techniques were used to predict the runoff from ungaged watersheds following urban development. A system analysis technique was used to evaluate the various combinations of system components, possible plant locations, and quality and quantity of reuse. The systems were optimized by computer techniques based on a net system cost given local site conditions as constraints. The cost of pollution control by conventional means and the value of the reused water were taken as benefits.

Four systems were considered for application to the Wilde Lake watershed in Columbia, Maryland. Three were based on the local storage concept with (1) potable reuse, (2) sub-potable reuse, and (3) pollution control only. The fourth system was a design for pollution control of the same area using conventional design approaches and methods. For the Wilde Lake watershed, the local storage and treatment system for potable reuse was found to be the most economical system. The local storage system for pollution control would have a slightly greater net cost than the potable reuse system. The sub-potable reuse system and conventional system were found to be considerably more expensive systems.

This program included the development of plans, schedules, and cost data for the demonstration of the local storage, treatment, and reuse of storm water and for the collection and analysis of data on urban hydrology.

2.1040, DETERMINATION OF THE FEASIBILITY OF REMOVAL OF ALGAL NUTRIENTS IN LAKE WATERS BY ION-EXCHANGE
O.T. ZAJICEK, Univ. of Massachusetts, Graduate School, *Amherst, Massachusetts* 01002

The objective of this project is to develop a simple and (relatively) inexpensive technique for the in situ removal of phosphate from natural waters by an ion exchange process. To this end, the behavior of various ion exchangers will be studied for exchange characteristics and selectivity for phosphate species as a function of pH, counter ions, temperature, and flow rate. In addition, attempts will be made to prepare phosphate specific ion exhangers. The information acquired will be used to develop a device and optimum conditions for the removal of phosphates from natural waters.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1041, DEGRADATION OF SEWAGE AND SOIL MICROORGANISMS
R. MITCHELL, Harvard University, School of Engineering, *Cambridge, Massachusetts* 02138

It is proposed that a project entitled 'Enzymatic Degradation of Sewage and Soil Microorganisms by a Marine Microflora' be initiated. The research would entail a study of predation by the indigenous marine microflora on those microorganisms carried into the sea as sewage or in run-off water. An attempt will be made to evaluate the significance of enzymatic degradation in the eradication of sewage and soil microorganisms from the sea. Special emphasis will be placed on the decomposition of Escherichia coli.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1042, OIL DISPERSION COALESCENCE BY POROUS SOLID CONTACT
L.A. SPIELMAN, Harvard University, School of Arts, *Cambridge, Massachusetts* 02138

Aqueous wastes, such as those from industrial processing or shipboard balast and bilge discharges, often contain significant amounts of extremely small oil drops which cannot be separated effectively by gravity settling alone. Flow of such suspensions through porous granular materials results in the continuous and efficient coalescence of the unsettable droplets into larger readily settled globules. The proposed study will endeavor to clarify the fundamental mechanisms underlying bed coalescence and thereby formulate general design criteria through a mathematical description of pressure drop and coalescence performance. The formulation will be guided by the experimental determination of the extent of phase separation and pressure drop under controlled variation of inlet drop size, suspension chemistry, medium grain size, bed depth, flow rate and grain surface treatment. The results of this study should be of use in the design of separation processes for treating waste aqueous oil dispersions prior to their discharge. The results of this work should also make clear the relative advantages of granular versus fibrous media.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1043, ENRICHMENT OF METALS IN SEAWATER BY FOAM PRODUCTION
T.R. GIBB, Tufts University, School of Arts, *Medford, Massachusetts* 02155

The work to be done relates to the general problems of the food- chain in the sea, pollution and the nature of the air/sea interface. It is expected to provide an inexpensive and chemically mild method of concentrating certain trace metals which are associated with strong ligands such as humic acids and aminoacids, or which are present as macromolecular species in seawater. It is directed at an analytical level just above the present state of the art viz: in what forms do the trace metals exist in seawater? The availability of larger quantities of metal compounds, concentrated by this non-destructive method, is expected to permit identification of coordination compounds, complex oxides, etc. The series of bubble generators will be used to produce a stable foam which will be separated from sea water. The composition of the foam will be evaluated by emission spectroscopy. Development of trace-analytical methods is proposed in those cases where more precise determinations are necessary. Approaches will include optical and X-ray emission spectroscopy.

SUPPORTED BY U.S. National Science Foundation

2.1044, TURBULENCE IN A STRATIFIED FLOW
W.R. DEBLER, Univ. of Michigan, School of Engineering, *Ann Arbor, Michigan* 48106

This research will experimentally investigate the generation, decay and structure of turbulence in a stratified flow. Transport phenomena will also be examined. The study will be carried out in an existing wind tunnel in which the flowing air can be stratified in the vertical direction by selective heating, meanwhile maintaining a low ambient turbulence level. The data that will be gathered, and the subsequent comparisons with homogeneous flows which will be made, should be of interest and value to researchers in meteorology and oceanography and in civil and sanitary engineering as related to water resources and pollution problems.

2.1045, REVERSAL OF EUTROPHICATION THROUGH ARTIFICIAL AERATION OF LAKES
R.C. BALL, Michigan State University, Institute of Water Research, *East Lansing, Michigan* 48823

Lake stratification results in uneven ionic distributions, biotic spatial restrictions, and certain other undesirable conditions. Artificial aeration may reduce or eliminate these conditions. Artificial aeration with compressed air may be accomplished either by thermal destratification, or by hypolimnion aeration. In the latter case, oxygen is added directly to the bottom waters without complete mixing of the water mass. We will study the effects of both systems on two northern Michigan lakes located in the Pigeon River State Forest. Field studies will be conducted during the summers of 1969 (control) and 1970 (test). The lakes will be aerated during the latter period. We will determine the effects of artificial aeration on: (A) physical- chemical properties, such as temperature, oxygen and phosphorus, (B) phytoplankton and periphyton, (C) primary production, (D) benthic fauna, (E) insect emergence rates, and fish depth distribution.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1046, THE INFLUENCE OF SOILS ON POLLUTION
A.E. ERICKSON, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL03030)

OBJECTIVE: Study pollutant fixation, movement and decomposition in soils, and the influence of the soil environment on the fixation and/or decomposition of pollutants. Modify soils to improve their efficiency in depolluting various wastes.

APPROACH: The equilibrium between various soils and various pollutants will be studied to determine the levels of the pollutants that are mobile in the soils. The movement of pollutants will be studied in the laboratory and the field by measuring effluent from percolation tubes as well as drainage water from drain tile, ditches or streams. Laboratory and field studies will be undertaken to determine the best environment for depolluting the percolating water. Soils will be modified so that conditions can be produced for depolluting the water passing through these soils.

PROGRESS: The water from three agricultural drainage tile lines, one drainage ditch and three streams from agricultural watersheds have been sampled throughout the year and analyzed for nitrogen, phosphorous, calcium, magnesium, and potassium. This work has been financed by the Michigan Water Resources Commission. A study of the nitrogen and phosphate counts of the soil and in the water at the shallow water table below lawns on various soil types surrounding a well-developed recreational lake was made to determine the influence of lawn fertilization and soil type on the nutrients entering the lake. This study was financed by a group of interested lake property owners. Another study considered the phosphate adsorbing capacity of soil horizon samples taken from a range of soil types. These data were interpreted on the basis of the capacity of the soil to remove phosphate from a percolating effluent, the phosphate content of the equilibrium leachate and the ability of these soils to recover their adsorption capacity with time. Financed by the Michigan Water Resources Commission.

SUPPORTED BY Michigan State Government

2.1047, NUTRIENT CONTROL PROJECT - DETROIT LAKES, MINNESOTA
W.C. LARSON, Detroit Lakes Engin. Dept., *Detroit Lakes, Minnesota*

Disposal of nutrients from municipal, private, domestic, and agricultural wastes in the Detroit Lakes, Minnesota area poses a serious problem owing to the high groundwater table, very permeable gravel aquifer, and wide interception routes of groundwater underflow. Several lakes in the chain of lakes in this area very important to the recreational needs of the community and valuable to the tourist industry have experienced catastrophic aquatic weed and algal growths in recent years as a result of nutrient enrichment. These lakes are interconnected by the Pelican River or its tributaries and are situated down gradient (to the southwest of Detroit Lakes, Minnesota). Since sources of nutrients are widely scattered it would not be economically feasible to intercept all waste outfalls with a central distribution system and provide subsequent treatment. It is proposed that nutrients in this sewage disposal system be intercepted or diminished in two different ways. 1) by dispersing the effluent from secondary treatment facilities on peat land and 2) by harvesting aquatic vegetation which contains nutrients. It is intended that by manipulation of natural

$ environmental processes the rate of eutrophication will be arrested at minimal expense.

2.1048, MATHEMATICAL MODEL OF STORM AND SANITARY INTERCEPTOR SYSTEM
C.E. BOWERS, Univ. of Minnesota, School of Engineering, *Minneapolis, Minnesota* 55414

The objective of this study is the development of a mathematical model of the interceptor system of the sanitary district, to assist in the operation of diversion structures in the trunk sewer system. A model has been developed to take precipitation data at several locations around the area as input and compute runoff in the trunk system, inflow to the interceptors and route the flow through the interceptors. It computes information on peak flows to assist in operation of diversion structures in the system, to assist in reduction of pollutants discharged into the Mississippi River. The final report is in preparation.

SUPPORTED BY Saint Paul City Government - Minnesota

2.1049, ECOLOGICAL STUDIES ON THE DYNAMICS OF PLANKTONIC BLUE GREEN ALGAE, WITH SPECIAL REFERENCE TO THEIR MICROSTRATIFICATION
A.J. BROOK, Univ. of Minnesota, School of Biological Sciences, *Minneapolis, Minnesota* 55455 (AT(11-1)-1820)

Although the collection of field data will be continued during the current year, the emphasis of the research plannedfor 1970-71 will be directed towards an experimental approach involving the manipulation of the artificial environments of columns established in the laboratory and in lakes. In the laboratory columns an attempt will be made to assess the influence of temperature, light and nutrients in the formation of algal strata. Observations on the occurrence of such strata of different lakes indicates that factor interaction must be involved and the proposed experiments will be designed to investigate certain of these interactions. In the plastic columns introduced into the study lakes, the primary focus will be in enrichments, the progress of which will be followed primarily by enzymatic assay monitoring. Enrichment will be induced on the one hand by over-turning artificially and so mixing the nutrient rich metalimnetic waters with its other poorer epilimnion, on the other by the addition of nitrogen and phosphorus.

Results: It has been established that not only 'Oscillatoria agardhii' but all major components of the phytoplankton tend to stratify in an orderly sequence in the lakes studied. Experiments with laboratory columns have demonstrated some of the effects of light on the formation of strata of 'Oscillatoria agardhii'. The columns established in lakes have indicated that enrichment stimulates the proliferation of 'Oscillatoria agardhii'. These column studies have also shown phosphatase activity in the epilimnion and thus some phosphorus deficiency in the algae. No severe phosphorus limitation has, however, been demonstrated, a sign which agrees with results obtained for other non-nitrogen fixing blue greens.

SUPPORTED BY U.S. Atomic Energy Commission

2.1050, PHYTOPLANKTON NUTRITION AND PHOTOSYNTHESIS IN EUTROPHIC LAKES
R.O. MEGARD, Univ. of Minnesota, School of Biological Sciences, *Minneapolis, Minnesota* 55455

The objective of this project is to analyse the nutritional requirements and the photosynthetic system of the phytoplankton in four Minnesota Lakes that receive nutrients from different sources and produce dense populations of nuisance algae. Algal nutrition, photosynthesis, and population densities will be studied before and after the nutrient influx to one lake is reduced, whereas nutrient- abatement programs for the others are either being discussed or they are in various stages of implementation. Analyses of algal nutrition, photosynthesis, and population densities that were begun during a retional limnological survey will be continued, but the emphasis will be somewhat different at each lake.

The research will monitor the effects of stopping the flow of sewage in the productivity of Lake Minnetonka. Advanced sewage treatment as a lake-management procedure and its effectiveness compared to sewage diversion will be evaluated in Shagawa Lake studies. The effectiveness of diverting sewage effluent from Sallie Lake and using the effluent for spray irrigation will be appraised. The results of the research project should assist the State in solving its lake pollution problems.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1051, LAKE ERIE DIKE
E. SILBERMAN, Univ. of Minnesota, School of Engineering, *Minneapolis, Minnesota* 55414

The Bethlehem Steel Corporation at its Lackawanna, New York plant proposes to contain the slag and other waste products previously dumped freely into Lake Erie by enclosing the waste area within a dike. It was the first purpose of the investigation to determine the optimum outline and structure of the dike to (1) limit interference with navigation into Buffalo Harbor by wave reflection and refraction and (2) prevent contamination or silting of the several adjacent water intakes, especially the Erie County Water Authority and the City of Buffalo intakes. This phase of the study was made by means of a physical model of the east end of Lake Erie at a distorted scale of 1:600 horizontal and 1:60 vertical and has been completed. A second phase of the study involves model tests in a wave tank of the dike cross section to design its reflection characteristics. One to 50 and one to 34 scales are being used.

SUPPORTED BY Bethlehem Steel Corporation

2.1052, NUTRIENT ASSIMILATION RATES - FIELD STUDIES
W. ABBOTT, Gulf Coast Research Laboratory, *Ocean Springs, Mississippi* 39564

A series of estuarine ponds have been formed by capturing a bayou channel between levees. The ponds are utilized for factorial experimentation on effects of various nutrients in multiple dose combinations.

Phosphorus studies have shown that the ultimate fate of an added tracer spike is conditioned by the recent fertilization history of the pond. Ability of the whole pond ecosystem to function as a sort of 'phosphorus buffer' is indicated by the results.

Repetition of phosphorus studies and studies on the nitrogen cycle are planned for the near future.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1053, ANIMAL WASTE UTILIZATION FOR POLLUTION ABATEMENT
O.E. CROSS, Univ. of Nebraska, School of Agriculture, *Lincoln, Nebraska* 68503

The proposed research plan involves laboratory and field investigations aimed at determining the maximum allowable rate of applying livestock manure to cultivated soil without causing pollution of surface runoff or underground water.

Field investigations would include surface runoff water and underground water analysis as influenced by: 1. Low, medium and high application rates of beef feedlot manure. 2. Plowing the manure under to depths of 24", 12", and 8". 3. Test plots set-up on fine textured soil and coarse textured soil. 4. Two plant population densities. 5. Manure to be applied in the fall in accordance with normal feedlot management practices. 6. Irrigation of test plots to follow recommended practices.

Laboratory investigations would involve: 1. Analyses of surface runoff and underground waters. 2. Analyses of change of physical, chemical, and microbiological changes of the soil. 3. Analyses of plant response and plant root growth.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1054, WATER-QUALITY REGIMEN OF TAHOE-TRUCKEE SYSTEM
J.V. SHARP, Univ. of Nevada, Desert Research Institute, *Reno, Nevada* 89507

2. WATER QUALITY

The principal objective is development of a digital simulation model which will simulate inorganic water-quality records under various regimes of flow and waste disposal in complex hydrologic systems which include ground-water and dispersed components. A second objective is to develop methodology for building a water-quality model from intensive, short-term water-quality records. Although the model is being developed on the Tahoe-Truckee system, basic concepts used in its formulation are independent of the system, permitting transfer of the conceptual model to similar hydrologic systems.

A preliminary model has been developed for the upper part of Tahoe- Truckee system. This model, based on eighteen months of data, simulates total dissolved solids. Research pertaining to 1) modeling, 2) investigation of environmental/human factors, and 3) data collection will be continued during FY 1971. The model will be extended to the remainder of the system, refined, and expanded to simulate individual constituents. Investigation of environmental/human factors and their relation to inorganic water quality will continue and results will continue to be used for refinement and testing of the model. The model will be tested on the Tahoe-Truckee system by comparing simulated data with 1) limited historic data available at Farad-Floriston, and 2) data collected as a part of the research. A comprehensive report on development and operation of the Tahoe-Truckee model will be submitted at the end of FY 1971.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.1055, ANALYSIS OF THERMAL POLLUTION DISPERSION
R.C. AHLERT, Rutgers the State University, School of Engineering, *New Brunswick, New Jersey* 08903

The purpose of this research is to describe the dispersion of thermal effluents. Molecular and turbulent diffusional coefficients will be used to generate temperature gradients in both longitudinal and normal directions. Models which characterize these temperature gradients in terms of outfall temperature, relative effluent flow rate, and outfall location will be developed. Because of the contributions of natural convection in some outfall configurations, laboratory experiments will be used to clarify the contribution of stratification or natural convective effects in the development of cross-sectional profiles.

Reaeration processes including pollution demands, interfacial transport and photosynthesis are nonlinear in temperature. Therefore, the model of stream behavior that assumes the stream to be a continuous reactor with both longitudinal and normal temperature gradients will be more precise than earlier models involving cross-sectional uniformity. Once appropriate temperature profiles have been developed for typical thermal effluent situations, these relations will be coupled with mass and energy balances. The ultimate result will be a clearer picture of the effect of thermal pollution on total stream properties.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1056, PHOTOSYNTHETIC REAERATION IN THE UPPER PASSAIC RIVER
J.V. HUNTER, Rutgers the State University, School of Agriculture, *New Brunswick, New Jersey* 08903

The purpose of this research is to determine the contribution of photosynthesis to the reaction of the upper Passaic River, and to determine the effect of this photosynthesis on the dissolved oxygen level - specifically, the diurnal fluctuations, in both a natural state and under conditions of artificial aeration.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1057, INSTREAM AERATION AND PARAMETERS OF NITROGENOUS BIOCHEMICAL OXYGEN DEMAND
W. WHIPPLE, Rutgers the State University, Water Resources Research Inst., *New Brunswick, New Jersey* 08903

The proposed investigation involves laboratory and field investigations to determine the explanation for the very high deoxygenation parameter observed downstream of artificial aerators installed in polluted rivers. This effect has been noted in a previous research and demonstration program involving the same principal investigators and others at the N.J. Water Resources Research Institute. Field tests will be made with mechanical aerator and oxygen diffuser equipment in the Passaic River, New Jersey, and samples and data will be obtained from other sites. Laboratory tests will be made, with and without nitrifying inhibitors, to determine the part played by dissolved oxygen level and turbulence in the reaction. Observations of nitrifying populations will be made by a microbiologist. The objective is to determine appropriate parameters for systems analysis for location of instream aeration stations.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1058, OXYGEN REGENERATION OF POLLUTED RIVERS
W. WHIPPLE, Rutgers the State University, Water Resources Research Inst., *New Brunswick, New Jersey* 08903

The purpose of this project is to demonstrate the effectiveness and economy of commercially available equipment in restoring to satisfactory dissolved oxygen levels the polluted waters of one small river, the Upper Passaic, and one large navigable river, the Delaware. After detailed analysis and preparation, aeration units of several types, of a size sufficient to materially change the oxygen level, will be installed on the Passaic River. Utilizing information gained from this portion of the study, aeration equipment will be installed on the banks of the Delaware. By field tests and dispersion analyses, the optimum configuration and type of stations, adapted to affect entire cross sections without interfering with the navigation, will be obtained.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

2.1059, ACID WATER TROUT STUDIES
R.H. SOLDWEDEL, State Div. of Fish & Game, *Trenton, New Jersey* 08625

Objective: To determine the means necessary to render acid water (pH 4.3 - 5.5) streams and lakes throughout the state capable of supporting brook trout populations for the purpose of angling.

Procedure: The monitoring of daily stream flow and pH data will be continued in Oyster Creek in conjunction with the U.S. Geological Survey Water Resources Division. Efforts will be continued to press for the development and activation of a pH recorder suitable for this purpose.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1060, NEUTRALIZATION EXPERIMENTS
R.W. STEWART, State Div. of Fish & Game, *Trenton, New Jersey* 08625

Objective: To evaluate the use of lime as a means of improving the habitat and fish population potential in Lakes No. 1 & 2, Winslow Tract.

Procedure: Neutralization experiments previously conducted at Lakes No. 1 & 2, Winslow Tract, as part of Jobs I-3 and I-4, are being combined herein.

The purpose of this segment is to prepare for publication a formal report on the results of this work.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1061, REACTION CAPACITY OF STREAMS IN NEW JERSEY
O.O. WILLIAMS, U.S. Dept. of the Interior, Geological Survey, *Trenton, New Jersey* 08607

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of New Jersey.

Purpose: To determine the ability of the state's streams to assimilate pollution loading.

Methods: Empirical relations developed by Langbein and Durum will be used to compute the reoxygenation coefficient (k2) of the Streeter- Phelps equation for a selected stream reach. Observed D.O. and B.O.D. values will be used to compute first (k1) and second (k2) coefficients for comparison with the coeffi-

cients derived using the empirical relations. Computer programs will be developed for computation of reaeration capacity of streams in New Jersey.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.1062, CHANNELIZATION STUDIES
R. FIFE, U.S. Dept. of the Interior, Bureau of Reclamation, *Albuquerque, New Mexico* 87103

Work is being done on the Middle Rio Grande Project, New Mexico, from Cochiti Diversion Dam to Elephant Butte Reservoir. The three original features of the program are: (1) the evaluation of river channel improvement by jacks (structural shape); (2) the evaluation of channeling water through low-flow conveyance channels; and (3) the determination of the efficiency of settling basins for sediment control.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.1063, RESEARCH ON PHYSICAL ASPECTS OF THERMAL POLLUTION
T.R. SUNDARAM, Cornell Aeronautical Lab. Inc., *Buffalo, New York* 14221

The program is concerned with three problems on the physical aspects of thermal pollution. The first problem is concerned with the study of the mechanisms responsible for the formation and maintenance of the basic thermal structure of stratified lakes. The second problem is concerned with the effects on this basic thermal structure of thermal discharges at or below the level of the thermocline. The third problem area is concerned with the study of the nature of the mixing processes at the interface between a warm layer of water and underlying cooler water. Significant new results have been obtained in all three problem areas. A mathematical model has been constructed for the stratification cycle of temperate lakes and the results of this model give very good agreement with actually observed thermal structures. It has been shown that thermal discharges at or below the level of the thermocline may lead to increases in the length of the stratification period as well as the volume of the epilimnion. It has also been demonstrated that while the transfer of heat across the interface between the warm layer and underlying cooler layer is severely inhibited by the stable buoyancy gradients, the transfer of momentum is influenced to a lesser degree.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.1064, EVALUATION OF LOW-FLOW AUGMENTATION ON THE CHEMISTRY AND BIOLOGY OF THE BUFFALO RIVER, BUFFALO, NEW YORK
R.A. SWEENEY, State University of New York, Graduate School, *Buffalo, New York* 14222

The purpose of this three (3) year study, which was initiated in 1967, is to ascertain the effects of the Buffalo River Improvement Project on the chemistry and biology of the Buffalo River. (Through the Buffalo River Improvement Project, 100 mgd is added to the river to augment the flow of this normally sluggish stream which receives both industrial and domestic sewage.) Sediment and water samples were gathered from four (4) stations during early June, late July and early September. Waters were gathered from four (4) stations during early June, late July and early September. Waters were quantitatively analysed for alkalinity, conductivity, pH, dissolved oxygen, solids, phosphates and nitrogen; sediment for solids, iron, oils, COD, BOD, chlorine demand, phosphates and nitrogen. The variety and number of macroinvertebrates were ascertained.

The latter indicates that there has been an improvement in the river down-stream of augmentation out-falls. However, the upper reaches are deteriorating in quality primarily due to domestic wastes.

SUPPORTED BY Allied Chemical Corporation

2.1065, EFFECT OF CHEMICAL STRUCTURE ON BIODEGRADABILITY OF ORGANIC MOLECULES
M. ALEXANDER, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00081)

OBJECTIVE: Determine the effect of structure of organic compounds on their biodegradability by natural communities of aquatic microorganisms. Establish biochemical principles governing the inability of natural aquatic microfloras to degrade synthetic organic compounds.

APPROACH: Appropriate classes of compounds which represent actual or potential water pollutants will be selected. The choice will also be conditioned by the availability of a reasonable number of model compounds, their stability and solubility and the potential for establishing principles relating structure to biodegradability. On the basis of prior investigations using soil or sewage organisms, our own or studies of others, if is expected that the investigations will include the effect of type, number and position of substituents, branching, N- alkylation, unsaturation and ether and thioether linkages on the ability of natural populations of aquatic microorganisms to degrade pollutants and model compounds representing potential pollutants.

PROGRESS: Tests based upon O(2) consumption demonstrated that microorganisms of soil are less able to degrade monomethyl-substituted than unsubstituted organic acids, while dimethylsubstituted compounds are strikingly resistant to biodegradation. Compounds containing a quaternary-carbon---like dimethyl-substituted malonic, succinic, valeric, glutaric, octanoic and undecanoic acids---are decomposed very slowly by heterogeneous communities; nevertheless, individual bacterial populations seem able to metabolize certain of these refractory molecules. Studies of cometabolism as a basis for the incomplete transformation of classes of non- or poorly biodegradable chemicals were continued. An Achromobacter cometabolizing 3-methyl- and 4- chlorocatechols produced from them the corresponding 2-hydroxymuconic semialdehydes. These products, which were not further degraded, were identified by UV and IR spectrometry and mass spectroscopy. These reactions appear to be catalyzed by an enzyme not previously described.

SUPPORTED BY U.S. Dept. of Agriculture

2.1066, COMPUTE SIMULATION OF DIFFUSION STUDIES
E. MEHR, New York University, Geophysical Sciences Lab., *New York, New York* 10003

The objective of this grant is the study of Monte Carlo simulation models for both diffusive and turbulent phenomena, and their application to water pollution problems.

The Diffusion Simulation Model will simulate streams and estuaries in both one and two dimensions. Further the third dimension will be simulated by means of two or three depth layers. Results will be checked by means of available data.

The Turbulent Simulation Model, the classical approach to estuarian diffusion problems, essentially involves specifying initial and boundary conditions, assuming or calculating values for mixing coefficients and solving the resulting differential equations. In applications the problem is frequently solved for a wide range of conditions and values for mixing coefficients since these quantities may not be known to a high degree of accuracy. A detailed discussion of the advantages and disadvantages of this approach is not the purpose of this report. Suffice to say that alternate approaches to the problem are of interest.

The purpose of this phase of the research is to investigate an alternate approach. The approach is to develop a model for small scale velocity disturbances that can simulate the role of turbulence in estuarian diffusion problems. The details on the structure of this velocity field is given in the next section; here a brief outline of the procedure is presented. The turbulent velocity field is simulated in the computer by specifying the flow characteristics in a combination analytic-random fashion. In principle the adequacy of the simulated turbulence can be checked by comparing the simulated Reynolds stress functions, velocity correlation functions and power and cross power spectral functions with observations from laboratory and field measurements. Once the simulation model has been judged successful then it can be applied to estuarian diffusion problems.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1067, MIXING, DIFFUSION AND CIRCULATION RATES IN OCEAN WATERS
W.S. BROECKER, Columbia University, Lamont Doherty Geolog. Observ., *Palisades, New York* 10964 (AT(30-1)2663)

Studies of the circulation and diffusive mixing in the deep and bottom waters will be carried out at several points in the ocean using the STD and radon techniques. Dye tracer experiments will be undertaken in near surface waters. Preparations for the GEOSECS program will continue. Our group will also participate in the JOIDES pore water program. Studies of gas exchange rates of CO2, O2 and radon in the laboratory and at sea will proceed as will investigations of the oceanic chemistry of Ba, Ra, and Pb.

Results: Measurement of exchange rates and residence time of the major water masses of the world through radioisotope techniques.

SUPPORTED BY U.S. Atomic Energy Commission

2.1068, INORGANIC SULFUR OXIDATION BY IRON-OXIDIZING BACTERIA
D.G. LUNDGREN, Syracuse University, Biological Research Labs., *Syracuse, New York* 13210

The objective of the research is to determine the role of biological sulfur oxidation by iron-oxidizing bacteria in mine water wastes. Reduced sulfur compounds are associated with iron containing materials (pyrites) present in coal which can serve as potential energy sources for these bacteria. Their oxidation can contribute to water pollution associated with both acid and alkaline mine discharges. Specifically, the enzymes (and the reactions catalyzed) involved in the oxidation of reduced sulfur compounds are being identified and characterized. The sulfur oxidizing enzyme, thiosulfate oxidizing enzyme, and the thiousulfate splitting enzyme have been isolated from Ferrobacillus ferroxidans. The important enzymes APS reductase and sulfite cytochrome c reductase have yet to be demonstrated in iron-grown bacteria. The effect of the presence of organic materials upon the aforementioned enzymes is also to be investigated. F ferroxidans is capable of growth on certain organic substrates which alters its autotrophic mode of life.

Sulfur and thiosulfate oxidizing bacteria have been isolated from alkaline mine drainage and their role in certain alkaline wastes is being assessed. Two organisms have been isolated: one produces some acid from thiosulfite oxidation, whereas the other produces alkaline products. How these organisms are related to those found in acid wastes and their contribution to pollution is being determined.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1069, OPTIMUM ECOLOGICAL DESIGNS FOR ESTUARINE SYSTEMS OF NORTH CAROLINA
H.T. ODUM, Univ. of North Carolina, Inst. of Marine Science, *Chapel Hill, North Carolina* 27514

This project will provide information on the feasibility of establishing associations of organisms in estuaries which can process man's wastes, metabolize inflow, develop the missing loops of the mineral cycles, and channel the fertility into one or more populations with food potential. Nine marine ponds will be constructed in a high marsh area along the coast of North Carolina. Three of the ponds will be continually seeded with mixtures of marine organisms (larvae, adults, plankton, micro-organisms, etc.) and will receive a steady flow of urban waste mixed with sea water. Three ponds will be seeded, but will be supplied only with sea water, i.e., no wastes. The remaining three ponds will receive the wastes mixed with sea water, but will not be seeded artificially.

Principal populations, some principal nutrient cycles and the total photosynthetic production and system respiration will be measured. Those populations of larger organisms which develop in large mass will be studied for growth rate and not production per area of meat potential.

SUPPORTED BY U.S. National Science Foundation

2.1070, MICROBIAL DEGRADATION OF HYDROCARBONS
J.J. PERRY, Univ. of North Carolina, School of Agriculture, *Raleigh, North Carolina* 27607

This project will investigate the possible use of certain types of bacteria for breaking down oil pollutants in water.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1071, DEGRADATION OF PETROLEUM AND RELATED COMPOUNDS IN THE BIOSPHERE
J.J. PERRY, Univ. of North Carolina, Graduate School, *Raleigh North Carolina* 27607

The research supported by this grant concerns the microbial degradation of hydrocarbon substrates in marine environments. The investigations consist of (1) a survey of the number and distribution of hydrocarbon utilizers in sea water, salt marshes and soil in the coastal regions by means of laboratory cultures of material from these areas, by counts of bacterial colonies that develop on hydro-carbon-coated glass slides after they have been buried for periods of time in selected environments and by determinations of the relative uptake of hydrocarbon by microoganisms in marine soil and water; (2) determinations of substrate specificity of organisms isolated on a single hydrocarbon or a single fraction of petroleum; (3) examination of the ability of organisms isolated in step 2 to grow on that substrate in the presence of crude petroleum or other fractions thereof; (4) studies of the degradation of complex petroleum by a mixed population of microbes that can degrade all the fractions of the complex petroleum; (5) determinations of the other requirements (mineral, vitamin, salinity, etc.) of marine hydrocarbon utilizers; and (6) the rate of turnover for hydrocarbons in marine environments. Data from these investigations will provide a basis for determining the effect of petroleum pollutants on the microbial population of the marine biosphere and the feasibility of cleaning up areas polluted with hydrocarbons by adding microbes which utilize hydrocarbons or by encouraging their growth.

SUPPORTED BY U.S. National Science Foundation

2.1072, THE MICROBIAL DEGRADATION OF HYDROCARBONS IN MARINE ENVIRONMENTS
J.J. PERRY, Univ. of North Carolina, School of Agriculture, *Raleigh, North Carolina* 27607

Studies will be conducted on the degradation of hydrocarbon substrates in marine environments. The total number and distribution of hydrocarbon utilizers in sea water, salt marshes, and soil in the coastal region of North Carolina will be investigated. This can be accomplished by plate counts, by counting the number of colonies that develop on hydrocarbon-coated glass slides after they have been buried for periods of time in selected enivronments, and by a determination of the relative uptake of hydrocarbon by the organisms in marine soil or water. The substrate specificity of organisms isolated on a single hydrocarbon or fraction of pertroleum will be determined. The ability of organisms isolated on one hydrocarbon or on a fraction of petroleum to grow on that substrate in the presence of crude petroleum or other fractions thereof will be examined. Studies will be conducted on the degradation of complex petroleum by a combined population of microbes that can degrade all fractions of the complex. The nutritional requirements (mineral, vitamin, etc.) of marine hydrocarbon utilizers will be determined along with the requirement for high salinity.

SUPPORTED BY North Carolina State Government - Raleigh

2.1073, CONCENTRATION OF PHOSPHATES FROM INDUSTRIAL WASTES BY BLUE-GREEN ALGAE
H.E. SCHLICHTING, Univ. of North Carolina, School of Agriculture, *Raleigh, North Carolina* 27607

This project proposes to study the abundance and species of blue- green algae in the estuaries and sounds and to determine whether practical use can be made of the ability of the blue-green algae to remove phosphate pollutants from water.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1074, FILTRATION OF KRAFT PULP LIQUOR THROUGH CHIPS
A.J. STAMM, Univ. of North Carolina, School of Forestry, *Raleigh, North Carolina* 27607

The purpose of the project is to investigate the purification of Kraft wash water by utilizing wood chips as a filtering medium. The wash water, containing insufficient pulping chemicals for profitable recovery, will be contacted with wood chips normally kept as inventory stock. In addition to reducing the alkaline pH of the Kraft wash water and adsorbing water soluble chemicals, the wood chips will undergo a mild prepulping action as a result of the contact with the wash water.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1075, EPIDEMIOLOGICAL STUDY OF CORRELATION OF WATER QUALITY AND DISEASE
L.J. MCCABE, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Cincinnati, Ohio*

Objective of the project is to provide a health effects base for water quality standards and water supply practices. There are two aspects of the investigation: one concerns the occurrence of disease that is known to be waterborne -- such as infectious disease outbreaks that are found to be transmitted by water; and the second is the investigation of the occurrence of chronic and metabolic diseases that may be caused or aggravated by organic and inorganic contaminants in drinking water.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.1076, STUDY OF WATER CURRENTS AND MOVEMENTS IN LAKE ERIE
W.J. LICK, Case Western Reserve Univ., School of Engineering, *Cleveland, Ohio* 44106

This research will be an extensive study of the circulation and water motions in Lake Erie. The analyses and results will be immediately applicable to, and useful in, pollution control programs.

The general program areas to be investigated are (1) the steady currents, (2) the time-dependent currents, and (3) thermal discharges in Lake Erie. A major emphasis of the program will be an investigation of water movements in a stratified shallow lake. The work will be theoretical and experimental in nature. The analyses will suggest further field observations and it is expected that field work will suggest additional theoretical and experimental work. It is believed that the investigation and solution of these problems will lead to a thorough understanding of the fluid dynamics of Lake Erie and will give a valid basis for pollution control programs.

SUPPORTED BY U.S. National Science Foundation

2.1077, RESEARCH INITIATION - THERMAL DISCHARGES
J.M. PRAHL, Case Western Reserve Univ., School of Engineering, *Cleveland, Ohio* 44106

This research will investigate experimetally the interaction of a warm, turbulent jet of water with a relatively cooler, quiescent basin of water over a range of Froude numbers, density difference ratios, and geometries that is relevant to actual river entrance flows and cooling water return flows to large lakes and oceans. The experiments will be performed on a laboratory sized model of the appropriate scaling. Coriolis effect will be neglected and the receiving basin will be a fluid of uniform density. A water table, 20ft. x 6ft. will be constructed to accommodate the experiments. The incoming jet velocity and temperature will be controlled and measurements of velocity and temperature profiles will be taken by scanning the jet at various locations with hot film anemometer probes and thermo-couples. The results will be recorded on a multichannel recorder. Variations in bottom slope can be accomplished by tilting the table, and end and side effects will be minimized by the judious adjustment of false, porous sides with controlled head behind them to match up with inflow at the sides and outflow at the end.

SUPPORTED BY U.S. National Science Foundation

2.1078, OIL SPILLAGE CONTROL
E.J. MARTIN, Cleveland Dept. of Pub. Util., *Cleveland, Ohio*

The work on this project is intended to solve the problem of removing oil that has been spilled on the surface of a river or lake. The approach will be to foam the oil, remove the foam by vacuum to an area where it is reconverted to a liquid and then to collect the liquid. The investigation will examine surfactant, air dispersing methods, vacuum recovery and foam breaking. These aspects will first be investigated in the laboratory where a choice of materials and techniques will be made. A prototype model for use on large tanks of material will be built and tested. A design for an operating model will be produced.

The work will be done at Horizon's Inc. at 2905 E. 79th Street, Cleveland, Ohio and the Bureau of Industrial Waste on Broadway in Cleveland, Ohio. The project will be started in FY 1970 and be completed in FY 1971.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1079, COMPARATIVE STUDY OF PHYTOPLANKTON IN NEW AND RECLAIMED ACID MINE DRAINAGE PONDS
C.V. RILEY, Kent State University, Graduate School, *Kent, Ohio* 44240

The purpose of the project is threefold: to compare the algal flora of new (very acid) and reclaimed (near neutral) strip mine ponds, to evaluate the role of algae in the reclamation process, and to study the nutrition of algae in an extremely acid ecosystem.

Water samples are taken weekly in both pond types and phytoplankton species identified and enumerated. Routine limnological measurements of pH, dissolved oxygen, hardness, alkalinity, and plant nutrients are also made.

Control and experimental columns of water are isolated in transparent polyethylene bags and resuspended in the ponds. Plant nutrients are added to the experimental bags to determine those ions which may be in limiting concentration in the ponds. The importance of chelators is to be carefully evaluated.

In an effort to estimate the importance of algae in the reclamation process, laboratory algal populations are cultured under semi-natural conditions and changes in water quality with time are studied.

SUPPORTED BY Kent State University

2.1080, STREAM REAERATION
W.R. DUFFER, U.S. Dept. of the Interior, Federal Water Quality Admin., *Ada, Oklahoma* 74820

The purpose of this investigation is to correlate stream reaeration rates with parameters expressing stream geometry and flow. This work will essentially extend the work of other investigators from tidal estuaries and streams having large flows to low-flow streams which are more representative of the southwestern United States.

In addition, the study will lead to an evaluation of the actual oxygen balance of the system with reference to photosynthesis, respiration, and diffusion. Further, the study will differentiate between these oxygen parameters in both the free-flowing stream and the benthos.

Present investigations are under way at the two test sites in Rock Creek, a stream of the Arbuckle impoundment system. One site is located upstream from a municipal sewage disposal plant, while the other is located downstream from the plant. Both sections of Rock Creek are characterized by limestone substrate. Plastic chambers will be used to separate the effects of photosynthesis, diffusion, and respiration under conditions of very little organic enrichment (upstream) and heavy organic enrichment (downstream).

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1081, REMOVAL OF NUTRIENTS FROM ENRICHED FLOWS & WASTE EFFLUENTS BY THE HYDROPONIC CULTURE OF SUITABLE FORAGE PLANTS & GRASSES
J.P. LAW, U.S. Dept. of the Interior, Federal Water Quality Admin., *Ada, Oklahoma* 74820

Hydroponic culture is a well-established method for growing many different types of plants. Normally, solutions are prepared with proper proportions of all required nutrients and are fed to the root systems of the growing plants. Algae have been grown for the removal of nutrients from lagoons receiving sewage effluents, but the difficulty of harvesting the growth makes this an undesirable approach.

It is proposed that higher plants can be successfully grown using a gravel-bed support in specially designed structures for the removal of nutrient materials remaining in waste effluents. Some of the principal objectives of this research are: 1. To improve the quality of surface streams receiving wastes and effluents by the removal of nutrients. 2. Finding the most suitable plants to be grown by this method. 3. Determine economic feasibility of the method, based on expected yield, cost of installation, operation, harvesting methods, etc. 4. Determine quantities of nutrients removed by the process. 5. Propose design criteria for application of the method to waste treatment installations.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1082, MINING-POLLUTION CONTROL TECHNOLOGY - OIL PRODUCTION GROUND-WATER RECLAMATION BY SELECTIVE PUMPING
L.G. MCMILLION, U.S. Dept. of the Interior, Federal Water Quality Admin., *Ada, Oklahoma* 74820

This is a field research project designed to develop and demonstrate a method for alleviating brine contamination in ground water reservoirs by selective development and pumping of the contaminated water. The contaminated area to be investigated is similar to many hundreds of other contaminated areas in the southwest, especially in West Texas and New Mexico where localized contamination has resulted from land disposal of oil filed brines. The project will develop guidelines for use by industry and governmental agencies in the correction of groundwater contamination and will report on the practicability of use of poor quality water for secondary oil recovery. Field site for the project is near Hobbs, New Mexico.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1083, RECLAMATION OF POLLUTED FRESHWATER AQUIFERS BY PURGING
P.A. DICKEY, Univ. of Tulsa, Graduate School, *Tulsa, Oklahoma* 74104

The proposed research plan is to investigate the feasibility of using fresh water to purge contaminants from polluted fresh water aquifers.

Records of governmental agencies would be studied, and residents living in areas of pollution would be interviewed. Standard mapping techniques would be employed to locate areas of contamination and to identify sources of contamination. Water testing of samples obtained from polluted wells will be employed.

Laboratory models would be constructed to simulate the performance of the aquifer and results would be scaled upward by simulation on an electronic computer.

A pilot project will be designed with complete cost estimates for the installation and operation of the pilot.

A cost estimate would be made of total aquifer reclamation.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1084, COASTAL DIFFUSION OF POLLUTANTS
D.J. BAUMGARTNER, U.S. Dept. of the Interior, Federal Water Quality Admin., *Corvallis, Oregon* 97330

The Georgia-Pacific Corporation, Toledo, Oregon currently discharges its kraft process pulp mill wastes to an ocean outfall which discharges approximately 6 million gallons per day through a diffuser section at a depth of 40 feet at a distance of 3000 feet off the Oregon Coast at Newport. The dilution achieved by the diffuser process and by the horizontally flowing field under the influence of natural forces will be investigated by frequent sampling of the near coastal waters, plus continuous monitoring of wind direction and speed. Current meters will be installed at various depths and at three locations in the near shore area to determine the relationship between the dilution of the field and the current structure. Additional surface current measurements may have to be made on the basis of drift cards or dye fields. Model tests will be performed in an 8-foot diameter, 3-foot deep tank to reproduce the hydrodynamic characteristics of the diffuser port and the density structure or the wind stress. This should, in addition to improving the methodology for describing jet diffusion, provide a method for estimating the influence of the non-steady current structure in the receiving fluid by comparing the observed performance in the prototype with the observed performance in the controlled model.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1085, ESTUARINE DIFFUSION OF POLLUTANTS
D.J. BAUMGARTNER, U.S. Dept. of the Interior, Federal Water Quality Admin., *Corvallis, Oregon* 97330

The most general characteristic of pollutants which plays a part in the assessment of their fate is concentration. Since the concentration is a function of its dilution in the environment as a result of mixing and diffusion, as well as decay of the component, it is of considerable importance to be able to determine how the concentration of a pollutant will vary in the receiving water at various locations and perhaps at various times if the pollutant or the environment is not in steady state.

Uncertainty exists with regard to the value of the turbulent diffusion coefficient to be used in problem analysis. To provide a means of determining this value at points in time and space, as well as providing additional understanding of the forces which influence estuarine diffusion, a predictive model of salinity will be constructed on the basis of time series analysis of observations in Yaquina Bay, Oregon.

Continuous recording salinometers will be installed approximately every five miles along Yaquina Bay to obtain the record of the time variation of salinity at the surface. Once a week, vertical traverses of salinity will be obtained to provide information on the vertical stratification in the estuary. If necessary, additional salinometers will be placed near the bottom to obtain information on the vertical distribution. Fresh water inflow will be estimated by stream gauging of the three principal surface streams in the area. Direct runoff and direct rainfall can be estimated. Information on tide height and frequency will be obtained from three tide gauges, while continuous information on wind speed and direction will be obtained at the entrance to the bay and other locations if necessary.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1086, MOVEMENT OF RADIONUCLIDES IN THE LOWER COLUMBIA RIVER
W.L. HAUSHILD, U.S. Dept. of the Interior, Geological Survey, *Portland, Oregon* 97208

The objective of this project is to quantitatively determine the concentrations and loads of specific radionuclides that are solutes and sorbed on sediments in the Columbia River from Hanford, Washington to the estuary. The spatial and temporal variation and distribution of the radionuclide concentration and loads are to be studied, and an approximate budget of the radionuclides is to be determined.

The physical, chemical and mineral properties of the suspended and streambed sediments are being studied; and these properties, insofar as is possible, will be related to sediment transport, sorbed radionuclides, and the equilibrium balance between the solute and sorbed radionuclide phases.

The extent and characteristics of sediments deposited on the streambed and sorption of radionuclides by these sediments in the

natural channel, reservoir, and tidal-affected reaches are being surveyed.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.1087, TRANSPORT OF SOLID SUSPENSION IN CONDUITS

W.H. GRAF, Lehigh University, School of Engineering, *Bethlehem, Pennsylvania* 18015

This proposal results from ideas formulated by the principal investigator during work on the project, 'The Transport of Solid Suspension in Conduits,' sponsored by the Federal Water Pollution Control Administration of the U. S. Department of Interior (research grant - WP-00838). Essentially, this proposal outlines further research to be done as a continuation of the present project. The research will be divided into two parts: (1) Design criteria for minimum transport velocities of non-depositing solid - liquid mixtures in pipe lines will be investigated. Only recently, the progress report of ASCE's Combined Sewer Separation Project points out a complete lack of data in this area. The proposed research will try to provide a modest contribution to adequate combined-sewer design, focusing primarily on suspended pressure conduit. (2) Further development of the modified Venturi meter to measure mixture flow rate and concentration simultaneously is suggested.

It is believed that the proposed research will provide further knowledge about the design of conduits transporting solid - liquid mixtures.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1088, RESPIRATION OF AQUATIC MACROPHYTES IN EUTROPHIC SYSTEMS

A.J. MCDONNELL, Penn. State University, Inst. for Res. on Land & Water, *University Park, Pennsylvania* 16802

The investigation is intended to incorporate results of prior laboratory studies on aquatic plant respiration into a model for stream analyses. Three basic models defining the control of oxygen uptake by (a) simple diffusion, (b) diffusion with reaction and (c) diffusion with reaction and internal storage will be structured. Simulation of the proposed models on an analog computer and subsequent comparison of computer output with observed data will follow.

The resulting mechanism will be incorporated into a stream oxygen model to demonstrate its applicability to calculation of the waste assimilation capacity of receiving streams and the evaluation of primary productivity in eutrophic streams.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1089, MUNICIPAL WATERSHEDS, URBAN-SUBURBAN TREES AND ENVIRONMENT, AND CORRELATING WATERSHED RESEARCH RESULTS

H.W. LULL, U.S. Dept. of Agriculture, N.E. Forest & Range Expt. Sta., *Upper Darby, Pennsylvania* 19082 (NE1603)

OBJECTIVE: Determination of sound management practices for municipal water yield and quality in the Northeast; determining how much the human environment is affected by urban and suburban trees and forest; and prediction of effects of forest watershed management practices in eastern U.S. from evaluation of all knowledge available.

APPROACH: Conduct cooperative studies on municipal watersheds on the effect of forest treatment on water-yield increases. Determine by field measurement the influence of species, age and spacing of street trees, residential-lot plantings, forested parks, and greenbelts on local climate, comfort indices, house-heating and -cooling, and disposition of storm runoff. Observe and evaluate projects of waste- water disposal on wooded lands. Analyze long-term streamflow records, available research results, and historical land use with respect to hydrologic condition of forest land and streamflow yield and distribution.

PROGRESS: A survey of municipal watersheds in the Northeast has found over 750 municipalities that derive water supplies or water-supply protection from city, state, or federal forested lands. Their total area is over 2 million acres. Forty-one percent is municipally-owned, 13 percent in private ownership, 36 percent in state lands, and 10 percent in federal. Timber harvesting is allowed by 54 percent of the municipalities and recreation-use by 59 percent. Watershed managers are principally concerned about water quality control, water yield management, and recreation. Sources of contamination: urban areas 38 percent of the 750 properties, recreation 36, industry 13, and logging 9 percent. Research has shown, country-wide, that substantial increases in annual water yield may be obtained by clearcutting, and substituting a protective ground cover, at levels of from 3 to 10 inches in the East and 2 to 18 inches in the West, varying with forest type and climate. Smaller increases can be derived from even-aged management under sustained yield programs. Costs of obtaining increased water yields are well below costs of distilling sea water, transmitting water from surplus to water-short regions, or water harvesting. Forecasts suggest that increased water yield from forest management, conservatively, could supply 50 percent of increased consumptive use expected by year 2020.

2.1090, DISPOSAL OF SLUDGE FROM ACID MINE DRAINAGE TREATMENT PLANTS

F.W. NIGGEMYER, Hi Hillsranch Incorporated, *Waynesburg, Pennsylvania* 15370

The objectives of this research and demonstration are to show that the sludge from the acid mine neutralization plants can be dispersed on the soil without pollution to the streams or ground water and also provide filteration of the solids without harm to the soil or vegetation. Unsettled lime neutralized mine drainings will be sprayed to demonstrate that sprinkler irrigation can be used to aerate the waste to remove the iron and the soil used to filter the solids. Controlled runoff will be maintained at the site. Various sprinkler types and vegetative cover will be used to optimize this operation.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1091, PHARMACOLOGY

J. DEFEO, Univ. of Rhode Island, School of Pharmacy, *Kingston, Rhode Island* 02881

One of our projects involves the subjection of a large number of extracts of marine plants and animals prepared by the pharmacognosy department of our college to a variety of in vivo and in vitro testing procedures to determine any pharmacological activity which might eventually lead to the isolation of a compound that would have importance medically or as an aid in experimentation on biological systems. The significance, therefore, lies in the possibility of finding either a new drug or a new source of an old drug.

Studies are also being conducted to determine what reactions marine organisms are capable of carrying out in metabolizing foreign organic compounds with which they may come into contact. These reactions are important in the handling of pollutants and their subsequent toxicity to the marine organisms themselves and other members of the food chain. In addition the experiments are designed to give information on the phylogenetic development of these metabolizing systems.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1092, BIOCHEMICAL OXIDATION OF HYDROCARBONS IN NATURAL WATERS

C.W. HOUSTON, Univ. of Rhode Island, Graduate School, *Kingston, Rhode Island* 02881

The proposed study involves the investigation of microbial degradation of hydrocarbons in natural waters. Although a great deal is known about the bacteria affecting health, relatively little is known about bacteria and biochemical processes that are fundamental to the assimilation of waste products that get into natural waters.

It is intended to evaluate factors which influence the clearance of hydrocarbons for natural waters by - 1. determining cultural conditions and composition in a natural water source and studying the dynamics of the system by a continuous culture study in a simulated environment; 2. investigating the role of co-oxida-

tion phenomenon in the accumulation of toxic hydrocarbon intermediates; 3. correlating the amount, type and the degradation rate of hydrocarbons to seasonal and cultural parameters for the purpose of recommending a suitable decontamination policy.

2.1093, DIFFUSION OF THERMALLY BUOYANT WATER JETS INTO A MOVING WATER STREAM
F.L. TEST, Univ. of Rhode Island, School of Engineering, *Kingston, Rhode Island* 02881

This project is concerned with the behavior of a two-dimensional plane jet of high temperature water diffusing into a moving water stream. The objective will be to determine by analytical and experimental means the velocity components and temperatures in the region of the diffusing jet as a function of turbulence level, stream velocity, jet velocity, jet angle, density difference, and relative geometry of stream and jet.

The experimental portion of the project will consist of studies of velocity and temperature perturbations resulting from warm water injected by a plane jet into open channel flow. Velocities and temperatures will be measured by hot film probes and thermistors, respectively. The analytical procedure will attempt to determine the solution to the diffusion problem from the basis of a theoretical model.

The results of this project can be used to improve the design of outlets for the discharge of high temperature water into moving streams.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1094, DEVELOPMENT OF A PROTOTYPE FOR REMOVAL OF ORGANICS FROM WATER
B.H. PRINGLE, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Narragansett, Rhode Island* 02882

For some time, use has been made of a carbon filter system for removal of organics from water supplies and extracted by chloroform and/or alcohol. The weight of these evaporated extracts has been used as a measure of the organics present in such supplies. This collection system itself is fraught with disadvantages, such as: (1) all organics are not removed in the collection process; (2) some organics are either not removed or only partially so; (3) there is interaction between organic molecules on the filter due to time; temperature, oxygen, and bacteria, results in compounds being formed which are not originally found in the water itself; (4) the weighed extracts are numbers representing no direct relation to public health. It is planned, therefore, to attempt to remove the first three disadvantages of the carbon filter system through the development of a closed extraction system. The fourth disadvantage, that of health implication of those organics found in water, will be reviewed. It is proposed, through the Sub-Committee on Organics other than Pesticides of the Public Health Drinking Water Standard Revision Committee, to attempt to derive a system for grouping organics such that a quantitation of the health implication of these materials might be obtained. This is also now under study.

Objectives: To develop a prototype system for the complete removal of organics from water such as to maintain the original identity of each particular compound contained in the water sample.

Accomplishments through FY-1970: Library research on procedures for removal of organics from water were continued.

Plans for FY-1971: Library research will be completed following which one or two procedures will be studied in the laboratory for their effectiveness in removal of various groups of organics which might be found in drinking water supplies. It is then planned, on the basis of this particular study to select the system found to be most effective for organic removal.

A pilot model prototype will be designed around the system selected. The prototype will then undergo study using various organic group systems as models. It will finally be tested with selected water systems for operational effectiveness. Finally, it will be field tested from which results, a field model will be derived. It is hoped that a laboratory prototype may be developed by the end of FY-71.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.1095, COLD WATER STUDIES - WALLUM LAKE
J.A. STOLGITIS, State Div. of Conservation, *Providence, Rhode Island* 02903

Objectives: To correct an acid condition in Wallum Lake through the application of ground limestone.

Procedures: This project will be a joint venture between the Massachusetts Division of Fish and Game and the Rhode Island Division of Conservation. Massachusetts will contribute one-half of the materials and labor involved in application. Rhode Island will, in addition, research the project and monitor the effects of liming. A summary of water quality data will be assembled. Also, the monitoring of water quality will continue at least quarterly throughout the duration of the project and annually therafter under Pond Surveys, Job I,I. Collections of bottom sediments will be analyzed to delimit exchange capacities prior to and following application of lime. Results will be published in a suitable journal.

Crushed limestone will be spread on the ice during February using farm tractors and fertilizer spreaders. A total of 350 tons of lime will be applied, which is approximately equal to 75 pounds per acre foot. It is anticipated that, at this rate of application, the pH can be raised at least 1.0 unit. It is also anticipated that a replicate application will be necessary during 1972. Evaluation during the summer of 1972 will dictate degree of success and direction of pursuit in the management of Wallum Lake.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1096, TEMPERATURE DISTRIBUTION IN THE VICINITY OF WASTE HEAT DISCHARGES
M.A. CHURCHILL, U.S. Tennessee Valley Auth., Div. of Environ. Res. & Dev., *Chattanooga, Tennessee* 37401

Research will provide means for predicting temporal and spatial distribution of excess heat in streams receiving condenser cooling water from steam-electric generating plants. This involves development of correlations for describing and predicting cooling rates based on meteorological data. The study also includes the development of mathematical models which account for the combined effects of cooling and mixing in rivers and reservoirs. There is particular interest in situations where the warm water, due to its lower density, stratifies in the surface layers of the receiving stream or reservoir and there loses much of its excess heat to the atmosphere before mixing takes place. Extensive data have been collected for such a thermally stratified river. Heat is distributed across the river immediately below the discharge allowing the situation to be analyzed as two dimensional.

Several more complex situations will provide data for the evaluation of temperature distribution in three dimensions. This situation occurs when discharge is into a reservoir or larger river. Data obtained below existing power plants will be used in developing and verifying the prediction methods.

SUPPORTED BY U.S. Tennessee Valley Auth.

2.1097, TRANSIENT FLOW MODEL FOR BETTER WATER QUALITY CONTROL, KENTUCKY RESERVOIR
B.J BUEHLER, U.S. Tennessee Valley Auth., *Knoxville, Tennessee* 37902

A mathematical model of Kentucky Reservoir is now under development to permit accurate determination of the transient flow at any point along the 184-mile-long reservoir. The transient flow is created by independent hydroplant operations at each end of the reservoir and by an uncontrolled canal connecting Kentucky Reservoir to Barkley Reservoir. Continuous knowledge of transient reservoir conditions are desirable to permit the controlled release of waste discharges to the reservoir in order to maintain high dilution and good water quality. As now envisioned, the model will be used to make 24-hour forecasts of the transient flows based on planned operations of the upstream and downstream hydroplants and the canal.

SUPPORTED BY U.S. Tennessee Valley Auth.

2.1098, TURBULENT MIXING IN SUBMERGED TWO-DIMENSIONAL WALL JETS

C.J. REMENYIK, Univ. of Tennessee, School of Engineering, *Knoxville, Tennessee* 37916

This project is concerned with turbulent mixing mechanisms which result as a stream of water bearing soluble or thermal pollutants is discharged into a second stream. The research objective is to provide fundamental information useful for engineering predictions of the pollutant concentration in the vicinity of the stream junction.

Applicability of the concept of eddy diffusivity to mixing flows will be investigated. The experiments will involve the measurement of Reynolds stress distributions in a two-dimensional wall jet of air.

Need for such an investigation is indicated by previous research which produced evidence that the application of the concept of eddy diffusivity to mixing streams may not be valid.

Goals: 1. Verify findings of last paragraph with (1a) A higher degree of accuracy than was possible previously and (1b) to do that by an independent method. 1a. Will be achieved with a hot wire anemometer equipped with a new linearizer circuit. 1b. Will be achieved by a single rotated hot wire method. 2. Gather experimental information to establish quantitatively details of the relationship between the turbulent shear stress and velocity distributions. The results will be used to construct a model modifying or replacing the concept of eddy diffusivity.

The results of this study will be applicable through scaling to the solution of problems existing today in the Southeastern United States due to thermal and chemical pollution of streams and lakes.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1099, CENTER FOR RESEARCH AND TRAINING IN HYDRAULIC AND HYDROLOGIC ASPECTS OF WATER POLLUTION CONTROL

P.A. KRENKEL, Vanderbilt University, School of Engineering, *Nashville, Tennessee* 37203

To formally establish a training and research center for the study of the hydraulic and hydrologic factors affecting water pollution control; to continue existing research endeavors in this area of study, and to instigate new investigations utilizing the Tennessee Valley Authority and the Corps of Engineers reservoirs as 'laboratories;' to establish an information retrieval center for the subject area that would be of world-wide value; to eventually construct a building solely for the purposes described herein; and to continue and expand the existing training program designed to produce engineers knowledgeable in hydraulics, hydrology, and wate pollution control. The project will be coordinated by a joint committee, comprised of members of the Federal Water Pollution Control Administration and Vanderbilt University.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1100, NATIONAL SYMPOSIUM ON THERMAL POLLUTION

P.A. KRENKEL, Vanderbilt University, School of Engineering, *Nashville, Tennessee* 37203

Project Objectives: To illustrate the need for research in thermal pollution, to elucidate the problems involved and their magnitude, to satisfy the need for exchange and dissemination of information concerning the thermal pollution problems confronting industry, municipalities and regulatory agencies involved in water pollution control work and to present the present state of knowledge in this rapidly growing field.

Plan of Operation: Two symposia will be held; one in Portland, Oregon, concerned with the biological and chemical aspects of thermal pollution; and the other at Vanderbilt University involving the engineering and economic aspects of thermal pollution. The meeting will be co-sponsored by Vanderbilt University and the Federal Water Pollution Control Administration and will utilize the most competent people available.

Need for Project: The United States has more than doubled its electrical power production every ten years since 1935 and the corresponding increasing quantity of heated water discharged to our receiving waters is expected to continue to more than proportionately increase. A definite need exists to increase public and technical awareness of the problems caused by thermal pollution and to stimulate research and adequate water quality management of water temperature.

D. Facilities Available: The staff and faculty of Vanderbilt University and the Federal Water Pollution Control Administration will cooperate in planning the conferences and making the necessary arrangements. In Portland, the Bonneville Power Administration Auditorium will be used for the meetings and the Sheraton Motor Inn for accomodations. The Nashville Meeting will utilize the facilities of Vanderbilt University.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1101, DISCHARGE OF NEGATIVELY BUOYANT FLUIDS

F.L. PARKER, Vanderbilt University, School of Engineering, *Nashville, Tennessee* 37203

Discharges from industrial plants containing higher concentrations of impurities than in the ambient fluid will act as negatively buoyant jets. It is possible for heated discharges, if the water was originally taken from cold hypolimnetic waters and discharged to warm epilimnetic waters to act also as negatively buoyant jets. The means of achieving uniform mixtures of the jets and the ambient fluids will be sought. The problem of discharge of a salt solution heavier than the ambient receiving fluid has already been studied. Parameters to be more comprehensively treated include the river densimetric Froude number; the jet densimetric Froude number; the jet angle with the vertical; the number, size and spacing of the jet ports, Those parameters can be varied by changing jet velocities, jet densities, and flume flow. The study of density stratification in the receiving fluid would also be studied. The items of ultimate interest are the definition of the distance required for attainment of a uniformly mixed profile. Those conditions most conducive to such mixing will be sought, as well as defining situations wherein complete mixing does not occur, for example, in a layer along the bottom. Preliminary data indicates that the data net may have to be increased near the jets and near the bottom to adequately define the movement of the jet material. If the initial jet momentum is insufficient to provide uniform mixing, downstream sections will be observed to detect further mixing due to dispersion and turbulent diffusion. Little work has been done in defining diffusion parameters in those cases where density differences exist; this shortcoming also exists for treatment of heated discharges. Concurrent with data collection and analysis, efforts will be made to use principles of fluid mechanics and mixing processes for establishing mathematical models. This project was begun in July 1969 and is scheduled for completion in September 1971.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.1102, TURBULENT DIFFUSION AND REAERATION IN NATURAL RIVERS

E.L. THACKSTON, Vanderbilt University, School of Engineering, *Nashville, Tennessee* 37203

Project Objective - To demonstrate the utility of refined tracer techniques in measuring flow times and dispersion in stratified reservoirs, with analysis of tracer to be made by activation analysis techniques; and to analyze newly available data on reaeration rates in natural rivers to test and demonstrate the applicability of theoretical mathematical models recently developed at Vanderbilt describing reaeration in natural rivers.

Plan of Operation -Tracer tests in a reservoir have already been performed and samples taken. They will be analyzed by activation analysis to produce time-concentration curves. New reaeration data will be obtained from Professor Ernest Tsivoglou at Georgia Tech. Some old data will be made useful by gathering hydraulic data not presently available on the streams used. All data will be processed and analyzed using a digital computer.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1103, EFFECT OF GEOGRAPHICAL LOCATION ON COOLING POND REQUIREMENTS AND PERFORMANCE
E.L. THACKSTON, Vanderbilt University, School of Engineering, *Nashville, Tennessee* 37203

The completion end result of this project will be the publication of a handbook on cooling pond sizes for various geographical locations in the United States. Such a publication will be of great value to Federal and State personnel responsible for the prevention of thermal pollution. It will be possible to determine reasonable sizes of cooling ponds for various sizes of power plants in different parts of the country. If the proposed plans do not conform to these average values, then more detailed scientific justification of the pond size chosen would have to be provided. The equilibrium temperatures have been calculated, the heat exchange coefficients have been determined and the net plant temperature rise for 1500-acre ponds for locations throughout the country have also been determined for 1000 megawatt plants. This project was begun in May 1969 and is scheduled for completion in August 1970.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1104, WATER QUALITY CONTROL
R.A. ELDER, U.S. Tennessee Valley Auth., Engineering Laboratory, *Norris, Tennessee* 37828

TVA is conducting research to develop engineering methods which can be used in the planning, design, and operation of river and reservoir water control structures associated with multipurpose water resource projects for management of water quality as well as water quantity. Specifically, the water quality management problem consists of developing methods of predicting water temperatures, dissolved oxygen concentrations, and flow patterns upstream from, within, and downstream from existing and proposed reservoirs for a given reservoir inflow- outflow program, including the effects of locating thermal or other industrial plants upstream from, on, or downstream from the reservoir. The ultimate goal of this research is to provide information needed to operate river and reservoir systems so as to make the best possible use of the water from the standpoints of quality and quantity.

The Engineering Laboratory is engaged in a continuing program of studies aimed at solving some related specific problems. Since 1965, studies have been conducted of the thermohydrodynamics of flows through several of TVA's existing reservoirs. A procedure was developed for predicting withdrawal layer thicknesses and internal flow distribution. Also a method was developed to predict the approximate discharge temperatures and dissolved oxygen concentrations from reservoirs. An effort was made to combine the laboratory's heat transfer studies with a mathematical model of reservoir stratification which was developed independently by one of the laboratory's consultants.

Important adjuncts to these basic studies are comprehensive field studies which are undertaken to verify the developed methods. To obtain simultaneous data on the many important factors which influence the temperature and certain other water quality characteristics of the outflow from a stratified reservoir, an intensive one-year study was made at TVA's 29-mile-long, 450-foot deep Fontana Reservoir in 1966. The analyses of these data is in progress.

SUPPORTED BY U.S. Tennessee Valley Auth.

2.1105, WASTE DISPOSAL BY HYDRAULIC FRACTURING
K.E. COWSER, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831

The hydraulic fracturing project is directed toward the ultimate disposal of intermediate-level liquid waste into deep, subsurface geologic formations, and the development of techniques to evaluate the suitability of a site for disposal by hydraulic fracturing. The specific objectives of the project are - (1) to improve the technique of hydraulic fracturing for ultimate disposal of radioactive wastes to the point of unqualified endorsement, (2) to validate new methods of presite testing, such as seismic techniques to locate the position and determine the orientation of induced fractures, (3) to demonstrate the applicability of the hydraulic fracturing method in a different geologic setting (western New York), and (4) to investigate hydraulic fracturing as a tool to measure the state of stress in the earth's crust, thus furnishing needed information to evaluate the site potential for waste disposal by hydraulic fracturing.

A 1500-foot-deep core hole was drilled in western New York State to explore the geology. This hole was then cased to convert it into an observation well. Three more observation wells were drilled at the corners of a square, and an injection well, also 1500 feet deep, was drilled at the center. A preliminary test injection of some 114,000 gallons of water was made at 1450 feet. It would appear that this injection resulted in a complex fracture pattern. The evaluation will not be complete until results of a radioactive tracer injection are available.

SUPPORTED BY U.S. Atomic Energy Commission

2.1106, RELATION OF PASS OPENINGS ON PHYSICAL EXCHANGE AND SALINITY IN ESTUARIES
F.D. MASCH, Univ. of Texas, School of Engineering, *Austin, Texas* 78712

It is generally accepted that there is not enough fresh water to meet the State of Texas' inland water requirements, and at the same time provide the fresh water necessary to maintain fisheries, pollution control, and recreation in the coastal bays and estuaries. Consequently, alternatives for meeting the desired salinity distribution and pollution control requirements in estuarine waters must be considered.

Most of the estuaries along the Texas Gulf Coast are separated from the Gulf of Mexico by a long thin chain of offshore or barrier islands. The exchange between gulf and bay waters takes place through a few natural and artificial passes through the barrier islands. It is the principle objective of this proposed project to determine whether the physical exchange of waters between the bays and gulf can be increased by either dredging new passes, or by enlarging existing passes through the barrier islands. In particular, the effects of modifications or additions of passes on the volume of physical exchange, the degree of mixing, and on salinity gradients is to be determined.

2.1107, HORIZONTAL DISPERSION IN SHALLOW ESTUARIES OF IRREGULAR SHAPE
F.D. MASCH, Univ. of Texas, School of Engineering, *Austin, Texas* 78712 (C-1158)

This proposed research involves the development and verification of a numerical model to evaluate transport characteristics in shallow vertically-mixed estuaries of irregular shape. The model is designed to assist in developing water quality requirements and evaluating the assimilative capabilities of the shallow irregular estuaries found along the Gulf Coast of the United States.

The study includes the following three phases: 1. Adaptation of an explicit numerical model of the two-dimensional convective dispersion equation to the irregularly-shaped estuary. 2. Evaluation of the dispersion coefficients from graphical and analytical considerations of the circulation and scale of turbulence in the estuary. 3. Verification of Phases 1 and 2 in a hydraulic model and then in the field.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1108, MIXING AND DISPERSION OF CONTAMINANTS IN RESERVOIRS
F.D. MASCH, Univ. of Texas, School of Engineering, *Austin, Texas* 78712

Field studies on the dispersion of a conservative tracer have been made in Lake Travis, Texas, a deep fresh water reservoir in which the predominant currents are generated by the wind. The purpose of the study was to examine the current velocity distribu-

tion with depth, the rate of dilution, and the dispersion coefficients for correlation with such parameters as the surface velocity and wave conditions. In all cases, time scales were limited to six hours and all tracer releases were made at the surface.

Results show that vertical and lateral diffusivities increase with the energy in the wave spectrum, but longitudinal diffusivity decreases. The dominant mechanisms for dispersion appears to be the shear flow mixing resulting from the vertical distribution of velocity.

The peak concentration in a dispersing cloud was found to decrease with the -2.5 power of time. This rate appears to be independent of the ambient conditions and the geometric characteristics of the site.

2.1109, METAL ION-CATALYZED OXIDATION OF PHENOLS AND AROMATIC AMINES

A.E. MARTELL, Texas A & M University System, Graduate School, *College Station, Texas* 77843

The purpose of this investigation is to study the kinetics and mechanisms of the oxidation of phenols and aromatic amines by molecular oxygen in the presence of manganese salts, and of other metal salts, as catalysts. Such reactions are of interest because of the use of permanganate, and because of the presence of compounds of other metals, in the purification of water containing phenols and aromatic amines derived from industrial contamination. Understanding of the reactions by which these substances are oxidized to innocuous compounds is expected to lead to improvements in methods of water purification.

The oxidation of phenols and aromatic amines will be studied with various oxidation states of manganese, and with the higher oxidation states of other metal ions such as iron, cobalt, and vanadium, as oxidizing agents. Similar reactions with molecular oxygen, in which the metal compounds have catalytic functions, will also be studied. Oxygen insertion reactions of the oxyanions of the metals will be investigated with isotopic 0-18 tracers. Special attention will be paid to oxygen- carrier systems in which the metal ions form complexes with molecular oxygen that are useful in the oxidation of organic compounds.

2.1110, FEASIBILITY OF THE USE OF LOCAL SOILS AS ION EXCHANGE MATERIALS FOR DISPOSAL OF LIQUID RADIOACTIVE WASTE INTO THE GROUND

K. MAHMOUD, Atomic Energy Establishment, *Cairo, United Arab Republic*

A study of the feasibility of the use of local soils as ion exchange materials for disposal of liquid radioactive waste into the ground.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

2.1111, MULTILAYER FILTRATION

K.J. IVES, Univ. Coll., *London, England, United Kingdom*

The theory of the filtration of water or wastewater through deep granular beds indicates that an improvement in design can be obtained if the size of the granular media decreases in the direction of flow. This has been demonstrated experimentally for particulate suspension in water by filtering in an upflow direction through size-graded sand, or by downflow through three layers of coarse anthracite, medium size sand and fine garnet. The three-layer design is to be tested for the filtration of flocculent metal hydroxide suspensions, and compared with normal sand filtration. Various arrangements of grain sizes and layer thickness will be tried to determine an optimum design. This aspect will also be explored theoretically. Other media (e.g., magnetite, glass beads, crushed flint, plastics) will be examined to see if they are of any practical use, and to see if the three-layer concept can be extended to several layers.

2.1112, EUTROPHICATION OF SHELTERED BAYS IN A LARGE LAKE

W.T. HELM, Utah State University, School of Natural Resources, *Logan, Utah* 84321

Bear Lake at the present time is a clear oligotrophic lake. With the recent increase in recreational use of the area, however, a number of boat harbors and breakwaters have been constructed. These structures have interrupted the normal shoreline currents. Along unprotected shores, the currents scour the bottom, limiting the amount and diversity of rooted vegetation and bottom organisms. Modification of this habitat by creating relatively quiet pockets protected from the wind driven water currents has encouraged the growth of a wide variety of organisms. The non-turbulent circulation pattern in these areas insures the retention of at least part of any intruding nutrient-rich water. The reactions of the rooted vegetation and benthic invertebrates to this altered environment will provide an assessment of the advisability of permitting such manipulations of the environment.

Measurements of selected physical and chemical parameters will be made at distances of a few millimeters to a meter or more from the bottom. Samples of plants and animals living on and in the bottom sediments will be collected in the same areas to determine how the differences in environment are expressed in the biota. Samples will be obtained from regions sheltered by breakwaters and harbors as well as from open, exposed littoral regions.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1113, WATER MEASUREMENT AND APPLICATION DEVICES

C.W. LAURITZEN, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00496)

OBJECTIVE: Develop methods of measuring and diverting water; methods of removing trash and sediment from irrigation water, and methods of handling and transporting movable irrigation and water application systems.

APPROACH: Devices for measuring and diverting water and handling and moving tubing will be designed, constructed and tested. Models will be built and tested under controlled conditions; and later, full-scale structures will be built and tested under operating conditions.

PROGRESS: It was demonstrated that lay-flat tubing could be installed as an underground conveyance structure. Still to be determined, however, are material requirements for the tubing and the conditions and operational techniques that will govern the probability of this approach as a method for conveying and distributing irrigation water.

SUPPORTED BY Utah State Government

2.1114, OPTIMUM DESIGN OF WASTE STABILIZATION PONDS

G.Z. WATTERS, Utah State University, School of Engineering, *Logan, Utah* 84321

This project will involve the measurement of flow circulation patterns and temperature distributions in the existing waste stabilization ponds operated by the city of Logan. The degree of density stratification will be observed and its effect on circulation patterns will be sought. The effect of wind on mixing will be measured.

With this information, a hydraulic model will be built and used to determine an optimum shape and hydraulic operation to best achieve optimum sewage treatment. Consideration will be given to location and types of inlets and outlets and placement of baffle systems, which will insure that the largest percentage of water will remain in the ponds the required treatment period.

The dispersion characteristics and general circulation patterns in the ponds will be evaluated by introducing fluorescent dye at the entrance to the pond and sampling periodically at predetermined grid points. The temperature of the samples will be measured and the samples will be sent to other researchers for bacterial and biological evaluations.

2. WATER QUALITY

The hydraulic model will be constructed in the Utah Water Research Laboratory. The model will have adjustable walls which can be formed into a large variety of shapes. By using different temperature waters it is hoped to model the effects of density currents.

The data from the field and model investigations will be used to formulate design recommendations and procedures for more efficient operation of waste stabilization ponds.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1115, LAKE DIKING AS A WATER POLLUTION MANAGEMENT TOOL
D.K. FUHRIMAN, Brigham Young University, School of Engineering, *Provo, Utah* 84601

This research will include the investigation of various alternative schemes for the location and operation of dike systems for Utah Lake as related to the water quality of the lake and the effect of the quality differences on the projected uses of the lake waters. It is expected that these studies will provide recommendations regarding location and management of the dikes which are planned for construction as part of the Central Utah Project, USBR. This project will provide planning and management details to enable better control of water quality as the future development of the lake goes forward. Project started June 1, 1970 and will be completed May 31, 1973.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1116, UNSTEADY FLOW AND SALINE INTRUSION IN ESTUARIES
R.A. BALTZER, U.S. Dept. of the Interior, Geological Survey, *Arlington, Virginia* 22209

It is of fundamental importance to recognize that flow in natural channels is basically unsteady flow. To be sure, the degree of its unsteadiness is often of such minor significance that, with sound reason, such flow can be assumed to be steady flow, thereby taking advantage of greatly simplified analytic representation. Nevertheless, proper and thorough understanding of the mechanics of unsteady flow is important per se in determining the discharge of regulated streams, in flood routing, in determining flows in tidal reaches of homogeneous density, and, in fact, in any situation where open-channel flow cannot be assumed to be steady flow. Moreover, an understanding of the mechanics of unsteady flow is fundamental to improving the understanding of saline intrusion and diffusion in estuaries.

The ultimate objective of this investigation is the development of mathematical models representing unsteady open-channel flow, particularly as associated with estuarine channels. These models, hopefully, could then be used to predict-- or using certain field obtained parameters -- to determine such quantities as outflow, saline intrusion, and effects of channel changes upon flow.

A thorough appraisal of present knowledge of unsteady, open-channel flow is being conducted, including categorization of flow types and their required mathematical representation. Mathematical models will be derived and evaluated utilizing various solution techniques employing both analog and high-speed digital computers. Selected field data will be employed in the evaluation process.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.1117, POTOMAC RIVER BASIN PROJECT
F.W. TRAINER, U.S. Dept. of the Interior, Geological Survey, *Arlington, Virginia* 22209

Streamflow augmentation through ground-water manipulation may offer a significant opportunity for increasing the flow of the Potomac River during late summer and early fall, when river flow is critically low for water-supply and waste-flushing needs in the Washington area. Ground water provides the low-flow discharge of the surface streams. The ground-water flow system is poorly understood, however, and additional studies are needed to determine the nature of ground-water discharge to the streams, in area and in time.

The study consists of two parts: (1) investigation of alluvial deposits, principally floodplain deposits along the Potomac River and its major tributaries; and (2) study of the consolidated rocks of the basin, with principal emphasis on limestones of the Applachian Valley. The following principal activities are planned: (a) Preparation of a geohydrologic map and supporting maps (e.g. water-table maps) and of an analog-study model. Both map and model are to be revised as necessary. They will provide the basis for planning the other studies below. (b) Reconnaissance of alluvial deposits (mapping, test-augering, geophysical work). (c) Limestone hydrology. (d) Supporting studies (stream- discharge studies, well inventory, observation-well program, quality-of-water studies of stream and ground waters). (e) Basic hydrology (several small studies of such topics as geochemistry of stream water, land-use problems, small-basin hydrology, and quantitative geomorphology).

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.1118, IMPROVING WATER QUALITY BY REMOVAL OF PESTICIDE POLLUTANTS WITH AQUATIC PLANTS
S.W. BINGHAM, Virginia Polytechnic Institute, School of Agriculture, *Blacksburg, Virginia* 24061

The proposed research involves investigations directed at the determination of the fate of pesticides in water and aquatic environment. The main approach is to determine the effectiveness of various aquatic plants for removal of pesticide residues from water.

In the growth chamber and greenhouse, radioisotopic methods will be used to evaluate the effectiveness of selected aquatic plants for degradation of residual pesticides. The plant tissues and water in the cultures will be sampled and radioassayed at intervals after exposure to radioisotopically labeled pesticides. Quantitative changes of the pesticide levels in the water and tissues will be determined by low background gas flow counting and/or liquid scintillation spectrometry of ground plant material, fractional extraction, or nutrient media. Degradation of labeled pesticides in aquatic plants will be evaluated by the collection of carbon dioxide. For partial degradation of the pesticide molecule, chemical extraction, fractionation, and chromatography of authentic compounds and unknowns will be involved.

For these studies, a few relatively new but already economically important pesticides will be selected. In a similar manner, specific aquatic plants that are important weed species will be evaluated for channels of pesticide degradation.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1119, THE RECOVERY RATE OF AQUATIC COMMUNITIES OF STREAMS RECEIVING ACID MINE DRAINAGE
J. CAIRNS, Virginia Polytechnic Institute, School of Arts, *Blacksburg, Virginia* 24061

The purpose of this project is to study the biological recovery from acid mine drainage into streams. Several control areas above the entrance of acid mine water will be compared with a substantial number of downstream areas to determine (1) the extent of biological damage, (2) the distance required for recovery, and (3) the influence of sewage, industrial wastes, and tributary streams upon the recovery process. With increased pressure on limited water resources it is essential that stream damaged by acid mine drainage be restored to a condition in which they can serve society in a variety of beneficial ways. In order to determine how these streams might best be restored, a good starting point is the restoration process in a natural situation.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1120, REMOVAL OF TRACE ORGANICS FROM WATER BY ADSORPTION ON COAL
P.H. KING, Virginia Polytechnic Institute, School of Engineering, *Blacksburg, Virginia* 24061

The proposed research involves laboratory investigations to determine the extent of adsorption of trace quantities of biochemically resistant organic materials on coal. Specific methods to be employed include both batch and fluidized column

studies utilizing a variety of selected solutes with a wide range of physical and chemical properties. Data obtained will be analyzed to show the kinetics of the adsorption process. The distribution of organic material between the aqueous phase and the adsorbed portion will be described if possible by an appropriate adsorption isotherm. The extent of adsorption on coal will be compared with similar data for activated carbon.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1121, ECONOMIC DISPOSAL OF WASTE SLUDGES FROM WATER TREATMENT PLANTS
P.H. KING, Virginia Polytechnic Institute, School of Engineering, *Blacksburg, Virginia* 24061

The disposal of sludges resulting from conventional water treatment processes such as coagulation, softening and filtration will be examined with a view of developing alternatives to disposal by dilution in cases where water quality stream standards would be violated or in situations where disposal to lagoons would not be feasible due to land costs.

Particular attention will be given to the parameters of treatment plant operation and to sludge conditioning techniques which result in rapid and thorough sludge dewatering on either open sand drying beds or through use of vacuum filters. The use of newly developed synthetic organic polyelectrolytes as a conditioning aid will be investigated. The economics of alternative methods of water treatment plant sludge disposal under varying conditions will be evaluated

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1122, UTILIZATION OF PHYSICAL AND MATHEMATICAL MODELS IN ESTUARINE WATER RESOURCES RESEARCH AND MANAGEMENT
W.J. HARGIS, Virginia Inst. of Marine Sci., *Gloucester Point, Virginia* 23062 (C-1428)

Increased use of hydraulic and mathematical models in research, planning engineering and conserving estuarine and coastal environments is important. The proposed project will utilize VIMS hydraulic model of the tidal James system and analogue, digital and hybrid mathematical modeling capabilities in a program of research designed to evaluate and improve the capabilities of each technique. Thus, the accuracy, precision and capabilities of all likely will be improved, or at least clarified.

It is expected that improved ability to predict the changes which will result in such biologically, economically, socially and politically important environmental factors as salinity distribution, currents sedimentation, bottom scour and shore erosion will result.

This program is relevant to the projected Chesapeake Bay Hydraulic Model.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1123, FRESH-SALT WATER IN ESTUARIES SEDIMENTATION PROCESSES
M.M. NICHOLS, Virginia Inst. of Marine Sci., *Gloucester Point, Virginia* 23062 (DA)

Technical Objective: To determine how suspended sediment accumulates in the fresh-salt water transitions of estuaries to cause turbidity maxima. Information developed should be of great value in terms of improving capability for analytical studies and in defining pertinent phenomena to be considered carefully in connection with hydraulic model studies. The phenomena proposed for investigation are extremely important to a better understanding of the shoaling characteristics and rates of shoaling in estuaries.

SUPPORTED BY U.S. Dept. of Defense - Army

2.1124, FUNCTION OF THE MARSHES IN REDUCING EUTROPHICATION OF ESTUARIES OF THE MIDDLE ATLANTIC REGION
R.A. WADE, Virginia Inst. of Marine Sci., *Gloucester Point, Virginia* 23062

Completed and current estuarine studies indicate that the nutrient budget of a highly enriched tidal system cannot presently be followed from the source of enrichment to the mouth. Analytical and physical data indicate that nitrogen and phosphorus compounds are 'lost' within the system and cannot be accounted for in soluble, suspended or deposited forms. The data indicate that adjacent marsh lands may be serving as nutrient storage areas, thus reducing environmental degradation and aquatic nuisance conditions in estuaries.

This study is designed to investigate the biology, chemistry, geology, and hydrography of a marsh adjacent to a highly enriched estuary and a marsh off a relatively unmodified system. Emphasis will be placed on water and soil chemistry with the necessary associated effort on classification, productivity, and hydrography.

Water samples will be collected at 2-hour intervals during spring and neap and dry weather and freshet periods. Complete chemical analyses of the samples will determine if the marshes serve as Purdy described the Washington, D.C., tidal pools, like lungs which purify on each tidal cycle.

The data will be analyzed in view of estuarine systems with and without associated marsh systems. The results should aid those agencies charged with decisions regarding the expendability of salt marshes.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1125, CONTROLLING THE LOCATION AND DISPERSION OF A THERMAL POLLUTING EFFLUENT
C.C. LOMAX, Washington State University, School of Engineering, *Pullman, Washington* 99163

The proposed research is to study the significance of controlling the location and the dispersion of a heated effluent discharged into a natural stream.

In the laboratory a dyed effluent will be injected into an open channel stream and the dispersion and location of the pollutant traced using photographic and fluorometric techniques. A fluorescein dye will be used as the pollutant. The following parameters will be investigated: 1. velocity and direction of the effluent stream at entry, 2. controls on the effluent at its point of entry to restrict turbulence and mixing with the main stream.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1126, FLUSHING OF SMALL SHALLOW LAKES
E.R. TINNEY, Washington State University, School of Engineering, *Pullman, Washington* 99163

In recent years the quality of lake waters has become increasingly important, first because of the growing demand for recreational uses and, second because the use of lakes and adjacent lands has accelerated their deterioration. Research studies too numerous to mention have dealt with the quality of lake waters but most of the previous work is related to eutrophication and the biological processes involved. In recent years some studies have been made on the currents in a lake which markedly affect the limnological behavior but these studies have, for the most part, dealt with mixing phenomena associated with wind and the density currents associated with solar heating and relatively cold inflows.

The question of how best to improve a small lake by enhancing natural flushing has received little attention. This proposal treats this particular problem with specific attention to the flushing of a small shallow lake. The primary objective of this study will be to clarify the flushing phenomena in small lakes, recognizing that mixing is also enhanced in natural water bodies by wind and solar heating. Hopefully the end result of this would be an explanation of flushing that would indicate how much and in what manner water should be introduced into a class of small lakes to achieve a prescribed flushing action.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1127, VERIFICATION OF MODELS USED IN THE MANAGEMENT AND CONTROL OF WATER QUALITY
B.W. MAR, Univ. of Washington, School of Engineering, *Seattle, Washington* 98105

2. WATER QUALITY

The proposed research involves the utilization of data and models resulting from the State of Washington Water Quality studies to develop a generalized model for intra-industry waste discharge, to verify existing water quality models, and to formulate and evaluate a water management policy based on discharge rights.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1128, SYSTEM ANALYSIS OF EUTROPHICATION CONTROL BY FLUSHING

R.T. OGLESBY, Univ. of Washington, School of Engineering, *Seattle, Washington* 98105

This research project is designed as an intensive study of a highly eutrophic lake before and after additions of nutrient poor flushing water. System analysis techniques will be applied to this information, together with data obtained through laboratory and field experiments, to meet the following objectives: (1) establish knowledge and information concerning the functional performance and effectiveness of flushing as a means of eutrophication control; (2) define the engineering concepts, design procedures, and design criteria necessary for the general application of this method; and (3) further understanding of the relationship of primary production to the environment in which it occurs. A further objective is to promote significant improvements in the water quality of that portion of the lake under study most densely inhabited and most intensively used for recreation.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1129, ESTUARINE ECOLOGY RESEARCH

E.O. SALO, Univ. of Washington, School of Fisheries, *Seattle, Washington* 98105

Objectives of the estuarine ecology project include: 1) To develop a mathematical model of important physical and chemical processes of the Duwamish Estuary, including rates of dilution of pollutants. 2) To investigate the ecology of pelagic and demersal fishes in the estuary and nearshore marine environment affected by industrial and domestic waste discharges. This investigation includes primarily studies of the estuarine and early marine life of immature chinook salmon (Oncorhynchus tshawtscha), including mortality, distribution and growth. 3) To determine factors that affect distribution, period of estuarine residence, timing of migration and behavior of adult chinook salmon before, during and after pollution abatement. 4) To develop an in situ bioassay technique for use with resident demersal fishes to procure essential biological input for the water quality simulation model. Observations will include the formation of abnormalities, mortality, growth, behavior, condition and resistance to disease. Water quality will be automatically monitored. 5) To determine the relationship between the quality and abundance of zooplankton and the horizontal and vertical stratification of water quality before and after pollution abatement in estuary.

Emphasis is being devoted to the Duwamish Estuary because a wealth of physical and chemical data exist there. The Municipality of Metropolitan Seattle and the U.S. Geological Survey maintain four telemetry stations in the estuary which record pH, dissolved oxygen, water temperature, conductivity and turbidity.

It is apparent that the effects of chronic pollution are subtle. Only through intensive sampling and sophisticated treatment of the data can they be measured.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1130, ESTABLISHING GUIDES FOR COORDINATING URBAN PLANNING AND THE DESIGN, ENGINEERING, AND CONSTRUCTION OF URBAN STORM RUN-OFF SYSTEMS

D.D. WOOLDRIDGE, Univ. of Washington, School of Forestry, *Seattle, Washington* 98105

Our current research 'Objectives and Comprehensive Planning for Urban Storm Water Removal' has developed several apparent factors: 1) There is increasing emphasis and desire to maintain natural environments particularly near water. 2) There is a very marked desire to eliminate pollution and restore a near natural ecological balance to lakes and river systems. 3) Compatible with these two objectives it is necessary to deliver storm water to each successively larger receiving water body at natural flow rates. Many have stated long-term goals of completely natural stream and river systems protecting stream vegetation, flood plains and natural hydrologic balance. Protected areas would be incorporated in a parks, walkways or a greenbelt system. We will continue to examine alternatives as our current study progresses.

This new proposal has a major objective of establishing step by step guides for accomplishing desired long term goals of urban storm water systems. It combines efforts of the University of Washington, King County, the Storm Water Control Subcommittee of the Forward Thrust Committee, Cities of Redmond, Bellevue and interested citizens and groups. It will detail major considerations of altered physical hydrology and soil erosion due to urbanization providing sources of technical information, local governmental regulations and related actual construction problems during urban development. In logical order, major phases from urban planning to complete development are: 1) planning, 2) design and engineering, 3) construction, and 4) financing (as incorporated in all phases).

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1131, LIMESTONE DRUM PRODUCTIVITY STUDY -- POPULATION STUDY

R. MENENDEZ, State Div. of Wildlife Resour., *Charleston, West Virginia* 25305

Objectives: To determine the effects of limestone drum installation on an existing fish population and to establish trout in formerly acid waters.

Procedures: Much of the allocated time will be devoted to preparation of the final report for both the Otter Creek (Work Plan 1) and Sherwood study (Work Plan 2). Population samples will be collected at designated stations in June and September. Fish collections will be made using electro-fishing gear and the mark and recapture method will be used to make population estimates. Data collected will be used to determine standing crop, growth rates, condition and mortality. Comparisons of population density, growth, condition and mortality with past years will be used to determine the carrying capacity.

Modified wolf-type traps will be installed in the stream at strategic locations to monitor fish movement both up and down stream. All trout collected will be marked for future reference and released.

A reconnaissance of the entire stream below the treatment station will be made to determine the location of suitable spawning areas and the use of the areas will be determined by observation. Several trout nests in both areas greatly affected by treatment and areas affected to a lesser extent will be excavated and egg or fry survival will be determined. Since the effects of treatment gradually diminishes downstream, knowledge of spawning and reproductive success may help establish the degree of acid neutralization necessary for successful reproduction. Data collected will also aid in determining if poor reproduction in the lower section is due to inadequate spawning areas or inadequate treatment.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1132, LIMESTONE DRUM PRODUCTIVITY STUDY-LIMNOLOGICAL STUDY

R. MENENDEZ, State Div. of Wildlife Resour., *Charleston, West Virginia* 25305

Objectives: To determine the limnological effect of limestone drum installation on selected streams and lake with special emphasis this segment on determining factors which limit bottom fauna production in the treated stream sections and the effects of trout predation on bottom fauna. Much of the allotted time will be devoted to preparation of the final report for both the Otter Creek study (Work Plan 1) and the Sherwood study (Work Plan 1).

Procedures: Artificial type substrates consisting of rock filled wire baskets and multiplate samplers will be placed throughout the stream in both treated and untreated sections. They will be serviced at six-week intervals and all organisms on the devices will be collected. Comparisons on abundance of organisms between treated and untreated sections can then be made.

Several sections of the stream below treatment will be blocked off for use as experimental units. These units will be located immediately below the treatment station where acid neutralization is greatest and at points downstream where neutralization is not as great. A known number and weight of trout will be placed in one unit at each location and one will remain free of trout. Bottom fauna numbers within each unit will be sampled monthly. Estimates of trout production in each unit will be based upon the changes in weight during one-month sampling intervals. The mean weight gain per recovered fish will be used in computing production whenever fish were lost from a unit during sampling. In the stream immediately below treatment, duplicate units will be set up; two containing a poor substrate and two containing an artificially prepared substrate. Known numbers and weights of trout will be placed in one each of the units. Differences in bottom fauna numbers in all units and in trout production in the two units will be measured. This additional field work will complement the overall study and tie together previous study.

2.1133, MANIPULATION OF RESERVOIR WATER FOR IMPROVED QUALITY AND FISH POPULATION RESPONSE
T.L. WIRTH, State Dept. of Nat. Resources, *Madison, Wisconsin* 53701

The number of small recreation reservoirs (50-200 acres) in Wisconsin's lakeless region is rapidly increasing. The formation of these impoundments alters the downstream channel while the fertility of the region causes the reservoirs to become highly eutrophic with limited aesthetic value due to aquatic nuisances. Recreational angling in the reservoirs appears to be depressed due mainly to intense algal growths and adverse aquatic environments (anerobic hypolimnion) which limit fish production in the steep-sided basins. Different management techniques are being applied to two in-line reservoirs. The downstream impoundment, which first filled in May 1967, is equipped with an outlet structure which continuously discharges hypolimnion water.

The upstream impoundment discharges epilimnion water and is being continually mixed to prevent thermal stratification. Quantity and quality (temperature, pH, D. O., transparency, major nutrients, and elements) of the inflow, and impounded waters are being measured throughout the year. Fish production and harvest are measured through techniques of population estimates, growth rates, age distribution, and angler's catch for comparison to previously measured levels. Invertebrate species composition and relative abundance are being measured in both of the impoundments and in the stream below the lower reservoir to ascertain changes brought about by manipulation. Aquatic vegetation changes are also being noted in the stream below.

2.1134, MODELING OF VENTED HYDROTURBINE REAERATION
W.C. BOYLE, Univ. of Wisconsin, School of Engineering, *Madison, Wisconsin*

The objective of this project is to obtain a generalized mathematical model for vented hydroturbine reaeration.

The experimental objective is to modify and to operate a small Francis turbine in a closed cycle, reservoir-pump-turbine system and to measure its performance as an aerator. The contribution of the vented draft tube to mass transfer will then be assessed separately from the gross systems transfer by means of a factorial test design. The interfacial surface area generated within the tube will be independently estimated by calculation and by photographic technique. With these estimates of surface area, the parameters customarily used to describe the performance of mixers and gas transfer equipment would be used to fit and to develop a correlation for all of these data.

The theoretical objective is to determine whether the draft tube functions in a manner analogous to that of a turbulent flow device such as a mixing orifice or to that of an impeller in a vessel.

The final objective would be to test the correlation against published field test data to determine its value for generalized prediction or modeling.

SUPPORTED BY Wisconsin State Government - Madison

2.1135, IMPROVING SURFACE WATER CONDITIONS THROUGH CONTROL AND DISPOSAL OF AQUATIC VEGETATION
H.D. BRUHN, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

This research proposes to investigate methods for the more efficient handling of cut aquatic vegetation. Feasible alternatives are sought for present slow and costly methods, which are at the same time compatible with over-all water management programs. Knowledge concerning the physical processing properties of aquatic plants is quite limited. Initially research would be conducted to determine how plants are affected by such standard operations as dewatering by crushing, homogenizing, maceration, etc., the objective being to identify potentially effective procedures.

Following acquisition of certain fundamental handling and processing data, the research can proceed on an applied basis. This second, pilot scale phase will attempt to determine the most practical combinations of methods for transportation and disposal of the entire, unprocessed plant, the entire plant after processing in some manner, complete disposal at the source, or other combinations.

The objective is to alleviate some of the bottlenecks which limit the capabilities of today's aquatic vegetation harvesting machinery to small fractions of rates achieved with agricultural machinery. The high cost of systems and procedures for mechanical control of aquatic vegetation have prevented realistic evaluations of its effectiveness as a management measure in eutrophic waters.

2.1136, SIGNIFICANCE OF ARTHROBACTER IN ECOLOGY OF WATER AND SOIL
J.C. ENSIGN, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

Bacteria belonging to the genus Arthrobacter are found in large numbers in soil and water. In some environs they are the predominating single group of bacteria. They comprise an important part of the stable autochthonous microflora. The purpose of this investigation is to explore the role of Arthrobacter in soil and water ecosystems. The mechanisms whereby these bacteria are able to maintain fairly constant and large populations, regardless of variations in environmental conditions, will be studied. Resistance to starvation, desiccation, adverse temperatures and other environmental conditions will be compared in both rod and sphere stage cells of the organism. The degradation of cellular macromolecules, reserve materials and intracellular pools will be followed during starvation. The results are to be compared to those obtained with Pseudomonas, which are part of the fluctuating, or zymogenous, microflora.

Members of the genus Arthrobacter have been found to actively degrade pyridine-ring compounds. A second aspect of this investigation involves studying the pathways and enzymes involved in catabolism of pyridine, nicotinic acid and several herbicide and insecticide derivatives of the pyridine ring.

2.1137, DISPERSION AND SALT WATER INTRUSION IN NON-HOMOGENEOUS POROUS MEDIA
J.A. HOOPES, Univ. of Wisconsin, School of Engineering, *Madison, Wisconsin*

In the study of dispersion in non-homogeneous porous media, a general solution for the distribution of a contaminant in flow through a layered porous media has been obtained. The resulting expression is simple and easily adapted to any arbitrary non-homogeneity. The basic feature of the analysis is that it treats the media as a continuum with a spatially varying dispersion coefficient. In this way the boundary conditions at the interface between successive layers are automatically satisfied.

For flow through two-layered media, arranged parallel to the flow direction, the analytical solution including the lateral dispersion has been obtained. In addition, a numerical solution for dispersion through a two-layered media, with its boundary at an arbitrary angle to the flow direction has been obtained.

Experiments have been carried out for layered systems, with layers oriented parallel, perpendicular, and at 45 degrees to the flow direction, over the Reynolds number range of 0.1 to 10. The results are in good agreement with the theoretical prediction.

Sea water intrusion into non-homogeneous, coastal aquifers, including the effects of dispersion and density difference, is currently being studied. Numerical solutions for the time average salinity and stream-function distributions for homogeneous and non-homogeneous aquifers have been obtained. An attempt is also being made to solve this problem analytically using a perturbation method. In addition, an experimental model is being constructed in order to test the theory.

SUPPORTED BY University of Wisconsin

2.1138, SHALLOW GROUND-WATER FLOW SYSTEMS IN RELATION TO INDUSTRIAL AND MUNICIPAL WATER SUPPLY AND WASTE DISPOSAL REQUIREMENTS
D.A. STEPHENSON, Univ. of Wisconsin, Graduate School, *Madison, Wisconsin*

The occurrence and seasonal fluctuations of shallow groundwater flow systems in various geologic environments of Wisconsin will be investigated within the framework of their relation to waste disposal practices of selected industries and municipalities. Solid and liquid waste disposal sites of the canning, dairy, and paper-pulp mill industries, plus municipal sanitary land fill sites will be areas wherein shallow flow systems are to be investigated.

It is anticipated that limited site selection criteria for the specified disposal practices can be developed based on the hydrogeologic framework. Where liquid wastes are being disposed of through spray irrigation or ponding, formulas will be developed to control rotation of equipment used for the waste effluents. It is further anticipated that more extensive investigations can be initiated following this preliminary study.

Surface and subsurface geologic, hydrologic, and geophysical data are to be collected, compiled, and interpreted. Laboratory and field studies will be interpreted to provide a basis for practical application of results.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1139, MICROFUNGI IN THE WATER, LITTER AND MUD OF A CATTAIL MARSH BORDERING LAKE BUTTE DES MORTS
L.L. TEWS, Univ. of Wisconsin, Graduate School, *Oshkosh, Wisconsin* 54902

The intent of the project is the determination of the number and types of microfungi in the water, mud and litter of a cattail marsh bordering the northeastern shore of Lake Butte Des Morts, a lake in the extensive Fox River-Wolf River System of central Wisconsin. Water, mud and litter samples will be collected aseptically monthly from June through July along a transect running perpendicular to the shoreline from open water to a zone where cattails no longer predominate. The samples will then be processed by filtration, culturing and dilution. After pure cultures have been obtained, the fungi will be identified and data will be recorded as 1) the frequency of isolation and 2) as either the number of fungi per 100 ml of water or the number of fungi per g of dry weight of mud or litter. The project is envisioned as the first step in determining the role microfungi play in the degradation of litter and pollutants passing through the marsh to the open water of Lake Butte Des Morts and the River System.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1140, WATERSHED RANGE CONDITIONS AND THEIR EFFECTS ON WATER QUALITY
A.A. BEETLE, Univ. of Wyoming, School of Agriculture, *Laramie, Wyoming* 82070

The major objective of this study is to relate variations in bacteria count and water chemistry with range conditions and use, therefore offering management personnel guidelines for multi-use management of watersheds. The objective will be accomplished by: (a) relating range conditions with type and amount of use, and (b) relating fluctuations of bacteria count and water chemistry with range use and conditions.

E. WASTE TREATMENT

Includes Sewage, Sludge, Or Wastewater Treatment Techniques Or Processes, Waste Reuse, Recycling, Or Related Commodity Development.

2.1141, GAMMA RADIATION OF TEXTILE WASTE WATER TO REDUCE POLLUTION
J.F. JUDKINS, Auburn University, School of Engineering, *Auburn, Alabama* 36830

The object of this proposal is to study gamma irradiation as a means of treating textile waste. The gamma irradiation will be supplied by a Cobalt-60 source with a variable geometry and a maximum disintegration rate of 12,000 curies.

Polluting agents common to textile waste are starch, basic hypochlorite bleach, dye compounds, sulfides, sulfites, and various detergents. The research will be broken down into three phases. These will be the study of the effect of gamma irradiation upon (1) aqueous solutions of individual polluting agents, (2) mixtures of the polluting agents, and (3) industrial samples of textile wastes. Experimental parameters, such as pH, dissolved oxygen concentration, temperature and radiation dosage will be varied.

The effect of the total irradiation dose and dosage rate on the starch samples will be evaluated by viscosity change, starch-iodine spectra and reducing sugars formed.

Standard chemical analysis will be used to determine the radiolysis products of the sulfides and detergents while radiolysis of the dyes will be evaluated spectrophotometrically. The chemical and biochemical oxygen demands of the radiolysis products and the original samples will also be measured.

Attempts will be made to predict optimum radiation dosage and dosage rate for degrading a particular waste to a satisfactory level. These predictions will then be tested by the radiolysis of actual textile industrial waste water samples.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1142, COLOR REMOVAL FROM TEXTILE DYE WASTES BY COAGULATION
J.M. JUDKINS, Auburn University, School of Engineering, *Auburn, Alabama* 36830

The treatment methods presently used for textile dye wastes have not been very successful in removing the color from these wastes. The discharge of highly colored wastes into streams is objectionable.

Laboratory studies using the standard jar test will be conducted to determine the extent of color removal from textile dye wastes by coagulation. Several coagulants, including alum and ferric sulfate, both with and without polymeric agents will be evaluated at different pH levels. Color removals will be measured with an electrophotometer. Initial and final BOD and sulfide concentrations will be determined on sulfur dye waste samples. The costs of the more promising treatment methods will be studied on a plant-scale basis.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1143, ELECTROMEMBRANE PROCESS FOR REGENERATING ACID FROM SPENT PICKLE LIQUOR
R.E. LACEY, Southern Research Institute, *Birmingham, Alabama* 35205

This project provides for the experimental investigation of an electro-membrane process for the recovery of sulfuric acid and iron or iron oxide from spent sulfuric acid pickling liquors. The investigation will determine the technical feasibility of the process in a bench scale operation, provide engineering data for the

design of larger recovery units, and develop engineering cost estimates to indicate the ecomomic feasiblity of the process. The bench scale studies will be directed at development of the configuration, mode, and conditions of operation required to minimize power requirements.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1144, DEMINERALIZATION OF WASTEWATER BY THE TRANSPORT-DEPLETION PROCESS
E.W. LANG, Southern Research Institute, *Birmingham, Alabama* 35205

The primary objectives are to determine the technical feasibility of the transport-depletion process for reducing the dissolved solids of secondary wastewater and to determine how well the transport depletion process can overcome the problems that have been encountered when conventional electrodialysis is used with wastewater. Other objectives include determining operating limits of the process, including types of feed pretreatment, when demineralizing secondary effluent, obtaining engineering design data and providing preliminary cost estimates to indicate the economic promise of this process for demineralizing wastewater.

To achieve these objectives, it is proposed to install and operate a transport-depletion stack and auxiliary equipment at a local sewage treatment plant. The treatment plant effluent, augmented with salts to bring the composition up to typical sewage effluent composition if necessary, will be demineralized over a wide range of operating conditions. The maximum demineralization capacity of the unit and the ability of the unit to operate without intolerable increases of electrical resistance with different types of water pretreatment, with a range of solution velocities within the stack compartments, and with high ratios of product-waste flows will be determined.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1145, ENTERIC VIRUS SURVIVAL IN AQUEOUS ENVIRONMENTS
E.W. AKIN, U.S. Environ. Protection Agcy., Gulf Coast Water Hygiene Lab., *Dauphin Island, Alabama* 36528

This project is concerned with determining the survival characteristics of human enteric viruses in the various aqueous environments used and consumed by man. This includes (1) estuarine water which may be utilized for recreation, and shellfish production and converting to community drinking water; and (2) freshwater, both natural and treated. Polluted surface water is increasingly becoming the initial source of our daily water intake. Sound judgments regarding the role of water in the transmission of disease by viruses are virtually impossible without critical knowledge of their survival pattern in the water environment. The intent of this project is to provide definitive information on virus survival so that a realistic indication of the health hazards of viruses in water may be intelligently assessed. Survival characteristics of poliovirus 1 in estuarine water will continue to be studied in the field with emphasis being placed on greater approximation of natural conditions. Laboratory studies will be designed to further identify the major factors contributing to the inactivation or protection of these viruses when they are suspended in various waters.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1146, TREATMENT AND DISPOSAL OF COMPLEX CHEMICAL WASTES
P.E. LAMOREAUX, State Geol. Survey, *University, Alabama* 35486

The proposed research will provide a means of treatment and disposal of complex chemical wastes consisting of five major efforts: (1) phase I - Drilling and testing of a deep well, (2) phase II - Completion of deep well for waste injection, (3) phase III - Surface installation for deep well system, (4) phase IV - Installation of surface plant for total treatment, and (5) phase V - Operation, maintenance and monitoring of total system.

All phases will be involved in standard procedures and concurrent research development of methodologies and/or testing techniques that will permit projections of the fate of the chemical wastes and assimilative capacity of underground formations for the waste to be studied. The deepwell phase will be carried to a point of decision and if the deep well does not prove feasible an alternative method of waste treatment and disposal will be initiated.

The work will be performed on the Reichhold Chemical property in Tuscaloosa.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1147, PRELIMINARY INVESTIGATION TO EVALUATE DEEP-WELL DISPOSAL POSSIBILITIES IN MOBILE, BALDWIN, AND ESCAMBIA COUNTIES, ALABAMA
W.E. TUCKER, State Geol. Survey, *University, Alabama* 35486

The high degree of industrialization and urbanization in southwestern Alabama makes it imperative that adequate methods of waste disposal be instigated if this area is to continue its growth and expansion. Surface disposal of wastes is in many ways unsatisfactory, and therefore detailed investigations of the possibilities of liquid- waste disposal in the subsurface are being conducted.

Electric logs are used to determine porosity and permeability of units which may be satisfactory for use in liquid-waste disposal. Rock cuttings from significant wells are described, analyzed, and tested in an effort to determine physical properties of significant units. Published literature and information from engineers in the field are used to obtain detailed knowledge on subsurface units in the area of study.

SUPPORTED BY Alabama State Government

2.1148, CONSERVATION OF FRESH-WATER RESOURCES BY DEEP-WELL DISPOSAL OF LIQUID WASTES
D.M. GRUBBS, Univ. of Alabama, Water Resources Program, *University, Alabama* 35486

This project will evaluate the geological and engineering parameters of subsurface rock formations which will permit disposal of liquid waste by deep-well injection procedures. Criteria and techniques will be sought which will have both quantitative and qualitative regional application in the development of underground disposal facilities. This will in turn alleviate the problem of usage of surface waters as carriers of waste effluent. Studies will be focused upon: 1. Derivation and analysis of information such as rock core and cuttings lithology, analysis of reservoir fluids, results of rock matrix and cementing material, electrical and other well-logging parameters, and petrophysical data such as porosity and permeability; 2. Laboratory analysis from simulated injection of liquid wastes into actual reservoir core samples to determine capacity, receptivity, continuity and compatibility, and pressure-time-distance response as a basis for prediction of systems behavior; 3. Development of mathematical models applicable to the identification and evaluation of potentially receptive disposal zones. Determination of restrictions to be placed upon types and volumes of liquid wastes which may be injected into specific deep-well reservoirs.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1149, COMPATIBILITY OF SUBSURFACE RESERVOIRS WITH INJECTED LIQUID WASTES
D.M. GRUBBS, Univ. of Alabama, Natural Resources Center, *University, Alabama* 35486

The proposed research plan involved laboratory determination of the long-term effects (compatibility) upon the physical parameters of subsurface rock formations resulting from the disposal of liquid wastes in deep-well injection practices. Purpose is to determine the extent of change in volumetrics and permeability of disposal reservoirs which may limit the economic practicability of this disposal method.

Laboratory methods will employ: 1. Chemical analysis of reservoir fluids, rock matrix, and cementing materials of selected subsurface reservoir rock samples. 2. Determination of potential receptive horizons. 3. Injection of typical industrial liquid wastes

into core samples under both surface conditions and elevated conditions of temperature and pressure over nominal to long periods of time to simulate actual reservoir conditions. 4. Re-examination of injected samples to determine changes in physical properties subsequent to long- term injection. 5. Chemical analysis of interstitial precipitates formed.

Data analysis will be directed toward prediction of effects of waste types on physical properties critical to receptivity and volumetrics of identified geologic horizons. Compatibility criteria will be formulated as a guide to the nature and volume of specific waste types which may be disposed of under limitations of local geologic conditions.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1150, EVALUATION OF AN OXIDATION-DITCH WASTEWATER TREATMENT PLANT IN SUB-ARCTIC ALASKA

R.S. MURPHY, Univ. of Alaska, School of Engineering, *College, Alaska* 99735

The project plan is designed to evaluate an existing oxidation- ditch wastewater treatment facility located in the sub-Arctic near Fairbanks, Alaska. Operation procedures, problems and economics of the system will be studied. Sufficient data will be obtained such that a mathematical model describing the biokinetics and oxygen requirement of the system can be formulated. Investigations will cover both the warm and cold temperature regimes as well as the transitions between these extremes.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1151, SPREADING TREATED SEWAGE FOR GROUNDWATER RECHARGE

H. SHIPLEY, Phoenix City Government, *Phoenix, Arizona* 85003

This project is to determine the feasibility of groundwater recharge by spreading treated sewage as part of future programs for waste water utilization, and to collect information for optimum design, management, and operation of spreading basins. A pilot project will be installed in the Salt River bed West of Phoenix. Effluent from a new activated-sludge plant will be pumped to the site and inflow and outflow for each test area will be recorded and observation wells will be installed. Studies will include loading rates, quality aspects in the percolation zone, etc.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1152, METHODS FOR WATER QUALITY IMPROVEMENT AND ITS STORAGE UNDERGROUND

H. BOUWER, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Phoenix, Arizona* 85040 (SWC-012-GG-1)

OBJECTIVE: Investigate the effectiveness of vegetation filtration, soil percolation, and underground storage for renovating secondary sewage effluent.

APPROACH: Laboratory and field studies are conducted to study the flow process in a soil profile under intermittent inundation and to evaluate the quality improvement of the effluent and the optimum management of recharge basins. The possibilities for nitrate control in the final product by induced denitrification will be investigated. The laboratory studies involve soil columns with recording tensiometers, gamma ray densitometry, and computer applications. The field studies are carried out at a three-acre pilot recharge project now under construction west of Phoenix.

PROGRESS: Nitrogen removal rates of 80% continued to occur with 2- 3 week inundation periods at the Flushing Meadows Project where Phoenix sewage is reclaimed by ground-water recharge with infiltration basins. Grassed basins not only yielded higher infiltration rates than non- vegetated or gravel-covered basins - they also yielded higher nitrogen removal. The nitrogen removal patterns in the field could be duplicated in laboratory columns. Gas chromatography studies on the columns and analysis of the soil from the recharge basins indicated that a significant amount of the nitrogen removed was stored in the soil, probably due to a reaction of ammonia with organic matter under anaerobic conditions. Nitrogen removal in the columns became less effective with inundation longer than 1 month and ceased completely after 3 months' continuous inundation. Soil percolation at Flushing Meadows gave essentially complete removal of biochemical oxygen demand and fecal coliforms. Phosphates were reduced by 90% and fluorides by 60%. Cost of reclaiming water in a full-scale recharge system is estimated to be $5 per-acre-foot. An equation has been developed from basic flow theory that predicts experimentally observed drainage-time relationships better than previously published equations. Its upper limit is the familiar Young's equation, and its lower limit is a two-parameter equation. This latter equation was first found when statistically fitting drainage-time relationships. It is useful in predicting the hydraulic conductivity and total volume of drainage from soil columns.

SUPPORTED BY U.S. Dept. of Agriculture

2.1153, ADVANCED WASTEWATER TREATMENT USING POWDERED ACTIVATED CARBON IN RECIRCULATING SLURRY CONTACTOR-CLARIFIERS

C.F. GARLAND, Infilco Incorporated, *Tucson, Arizona* 85703

The objective of this project is to determine the process and operating parameters for adsorption of dissolved impurities from the secondary effluent of a municipal activated sludge plant by powdered activated carbon in two stages of continuously recirculating slurry contactor-clarifiers. The proposed work includes: 1. Preliminary laboratory investigations to evaluate three different commercial grades of powdered activated carbon will be performed during the procurement and construction periods (10 weeks). Carbon coagulation studies, adsorption isotherm studies, and adsorption rate studies will determine which activated carbon will be used in the subsequent field operations. 2. A 10-20,000 gal/day, two stage countercurrent, continuously recirculating contactor-clarifier will be constructed and evaluated during continuous operation for a twelve-week period. The independent process variables of flow rate, activated carbon feed rate, and slurry solids inventories will be investigated over ranges sufficient to determine the optimum combination for removal of adsorbable substances as determined by COD measurements. A brief study will be made of a single-stage contacting system.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

2.1154, TUCSON WASTEWATER RECLAMATION PROJECT

P. BEERMANN, Tucson City Government, *Tucson, Arizona* 85701

The project objectives are to demonstrate the chemical, biological, and virological safety, and the aesthetic acceptability of including renovated wastewater as a dependable and substantial portion of the future Tucson water supply and to determine what species of fish will live and provide the optimum production and growth rate in renovated wastewater. The renovated water will be supplied from a pilot scale spreading basin - horizontal flow filtration facility and experimental ponds.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1155, TECHNICAL, ECONOMIC & LEGAL ASPECTS IN THE EXCHANGE OF SEWAGE EFFLUENT FOR IRRIGATION WATER FOR MUNICIPAL USE (TUCSON)

C.B. CLUFF, Univ. of Arizona, Water Resources Research Ctr., *Tucson, Arizona* 85721

This proposed investigation is designed to study the concept of exchange of sewage effluent in the Tucson area for irrigation water, as a management tool. This proposed exchange should accomplish the following: 1. Increase available municipal supplies by transferring water from agricultural use to municipal use with a minimum economic loss to the agro-industrial complex. 2. Provide a method whereby high quality water now being used for irrigation can be used for municipal use, with sewage effluent characteristically high in plant nutrients being substituted for agricultural use. 3. Reduce the pollution potential of sewage effluent by using natural processes occurring in the soil profile during normal irrigation application.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1156, TURFGRASS MANAGEMENT-USE OF RECLAIMED WASTE WATER - USE OF TURF AND ORNAMENTALS
G.S. GREENE, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-0206-4164-107)

OBJECTIVE: Study use of reclaimed waste water, including excess surface run-off, industrial waste and sanitary sewage; study use of turf and ornamental plants in public parks and golf courses; test water irrigation techniques.

APPROACH: Not provided.

PROGRESS: This project is being conducted in connection with the Environmental Modification Facility under the general direction of Dr. Richard Dassander. It is located on an 84 acre site at the Tucson International Airport, and includes the development of an urban park and recreation area containing a 16 acre lake complex, a small golf course and other attendant features. Its primary purpose is to provide research and demonstration of such facilities in an arid region, using only industrial waste water and flood runoff without utilization of ground water resources. Preliminary design work has been completed. No new work has been done this year, since funds for construction and capital improvements have not been available. The work of construction will necessarily precede the start of research and demonstration.

SUPPORTED BY Arizona State Government

2.1157, A UNIFIED APPROACH TO WATER, FOOD AND POWER IN A COASTAL DESERT COMMUNITY
C.N. HODGES, Univ. of Arizona, Inst. of Atmospheric Research, *Tucson, Arizona* 85721

The University of Arizona is developing a combination system for providing power, water and food. The system is designed for use, initially at least, in a coastal desert area.

Power is generated by a diesel-electric set. Waste energy from the diesel engine is utilized to heat seawater for a humidification desalination plant. The waste seawater from the desalination plant is used to provide the temperature and humidity control for a closed- environment greenhouse. Carbon dioxide from the diesel engine exhaust is used in the closed greenhouse to accelerate plant growth.

Various experimental components of the system have been constructed and tested at the Environmental Research Laboratory, Tucson, Arizona. A pilot facility has been developed at Puerto Penasco, Sonora, Mexico, in cooperation with the University of Sonora. A larger facility is under construction in Abu Dhabi, Arabian Gulf.

SUPPORTED BY Abu Dhabi Government

2.1158, GROUNDWATER RECHARGE AND QUALITY TRANSFORMATIONS DURING THE INITIATION AND MANAGEMENT OF A NEW STABILIZATION LAGOON
G.V. JOHNSON, Univ. of Arizona, Water Resources Research Ctr., *Tucson, Arizona* 85721

The overall objectives of the proposed study are, (1) to obtain field data on the interrelationships between seepage losses, groundwater recharge and associated water quality transformations, during the initiation of a new, raw sewage stabilization lagoon near Tucson, Arizona, and (2) to obtain information under controlled conditions on the effectiveness of turfgrasses to utilize N in stabilization lagoon effluent.

Existing research facilities located in or near the lagoon include PVC water sampling wells and access wells, used in conjunction with a recording neutron probe. Background information on water quality, water levels, etc. will be obtained prior to initiating the lagoon. During filling, seepage rates will be calculated and samples of effluent, pond water and ground water will be procured for chemical analysis. Water content profiles in access wells will characterize the growth and lateral spread of subsurface mounds in the stratified sediments underlying the lagoon. The natural sealing potential of benthic deposit will be studied, together with the effect of a benthic layer on quality transformations during seepage.

N-uptake by turfgrasses will be studied on 12 instrumented lysimeters. Three turfgrasses will be evaluated in four replications. Two of the replicates of each turf will be irrigated with effluent from the lagoon site and two will be irrigated with well water, supplemented with nitrogen equivalent to the concentration in effluent. Turf utilization of effluent N will be assessed by laboratory analysis of the clippings and soil solution samples from various depths in the lysimeter.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1159, REMOVAL OF PHOSPHATE AND SECONDARY B.O.D. FROM TERTIARY TREATED WASTEWATER BY AQUATIC ANIMALS
C.D. ZIEBELL, Univ. of Arizona, Water Resources Research Ctr., *Tucson, Arizona* 85721

The purpose of the proposed research is to test the practicability and methodology of phosphate removal from reclaimed wastewater by aquatic animals with subsequent harvest of these animals for a useful purpose.

Phosphate removal by present sewage treatment methods rarely is sufficient to prevent stimulation of undesirable algae growths. Rank algae growths are a secondary source for biochemical oxygen demand, they reduce the value of boating and fishing lakes and increase the difficulty of pumping reclaimed wastewater into permeable underground strata.

Project investigations will include: 1. Replicated experiments to measure rate of removal of algae and organic ooze (and incorporated phosphate) by selected fish and mollusks. 2. Experimental units at least 1000 gallons or larger depending on applicability. 3. Chemical analysis of water, bottom ooze and fish to evaluate degree of phosphate removal.

Data will be evaluated for practical application in sewage lagoons and reclaimed wastewater ponds with respect to recreation and domestic usage.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1160, HEAT AND MOISTURE CONDUCTION IN UNSATURATED SOILS
R.E. BABCOCK, Univ. of Arkansas, Water Resources Research Ctr., *Fayetteville, Arkansas* 72701

The object of this study is to solve the second-order, partial differential equations describing heat and moisture conduction in unsaturated soils. The set of initial and boundary conditions are those applicable to the process of simultaneously employing subsurface irrigation while disposing of nuclear reactor thermal waste water. The equations will be solved numerically in a piecewise manner using the 'leap frog' method. The analysis will be restricted to two dimensional conduction in a semi-infinite slab with a constant line source existing in the corner of the slab. Operations research methods will be applied to the model in order to schedule lateral spacing and irrigation flow rates for optimum plant growth.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1161, WATER AND WASTE WATER PURIFICATION
D.E. WEISS, Comm. Sci. & Indus. Res. Org., *Melbourne, Victoria, Australia*

The main effort has been the development of an ion exchange process of desalination ('Sirotherm') which uses hot water for generation of the resins. Now that resins with adequate physical properties have been devised, in association with local industry, work is proceeding on pilot-plant studies of the process.

In collaboration with the Australian Mineral Development Laboratory, an Asahi-type (Boby C1) continuous ion-exchange pilot plant has been successfully operated for partial demineralisation with almost theoretical consumption of acid and a lime slurry as chemical regenerants.

Work is proceeding on the use of finely divided, magnetic resins in other water treatment processes. Work has also begun on the removal of ammonia and nitrate from effluents.

SUPPORTED BY Australian Government

2.1162, REDUCING POLLUTION FROM POTATO AND ROOT VEGETABLE PEELING
A.H. BROWN, U.S. Dept. of Agriculture, Western Utilization Res. Div., *Albany, California* 94710 (W3-4-104)

OBJECTIVE: Devise peeling methods for potatoes and root vegetables which keep peeling residues separate from liquid effluent, to minimize pollution.

APPROACH: Modify present non-mechanical treatments such as lye or steam for softening or loosening the skin of tubers and root vegetables, leaving them as dry as possible. Devise new treatments as needed. Determine optimum concentrations, contact time, and temperatures. Develop mechanical methods for removal of softened tissue with a minimum of water. Evaluate solid peel residues for feed or other uses.

PROGRESS: Advice and guidance were provided for pilot and commercial scale extensions of our new dry caustic potato peeling method. A 5,000 lb. per hour dry caustic peeling system was installed in the Western Farmers Association plant, Aberdeen, Idaho, to test the commercial feasibility of the process. The pilot system was installed in parallel with a conventional lye peeler. The Potato Processors of Idaho Association cooperated in operation and evalution of the system. Results showed that the dry caustic peeling system not only eliminated the peel waste from the plant effluent, but it also resulted in lower lye consumption and lower peel losses. Lye consumption for the dry caustic peeling system was less than half of that used for the conventional peeler. Peel losses were reduced by about 30%. A 60,000 lb. per hour dry caustic peeling system has been placed in operation in Grand Forks, North Dakota. This plant is financed in part by the Federal Water Pollution Control Administration. Data collected from this installation will be made available to all potato processors. Field tests of the dry caustic peeling process were also made at two sweetpotato canneries. The process parameters must be slightly modified for sweetpotatoes, but the basic process developed for white potatoes can be applied to sweetpotatoes.

SUPPORTED BY U.S. Dept. of Agriculture

2.1163, EXPLORATORY STUDIES ON DISPOSING OF OR RECLAIMING FOOD PROCESSING WASTES
R.P. GRAHAM, U.S. Dept. of Agriculture, Western Utilization Res. Div., *Albany, California* 94710 (W3-1-150)

OBJECTIVE: Minimize pollution of land, waters and atmosphere from sources associated with food processing.

APPROACH: Study desalting of lye-peeling wash waters, including means for recovering salt or caustic. Reduce oxygen demand of liquid fruit-cannery wastes by enhanced oxidation of organic solutes. Reclaim water and brines by treatment of liquid effluents.

PROGRESS: Reclamation of olive storage brines is under study on a pilot scale in a project carried out by the National Canners Association and sponsored by the olive industry and the Federal Water Pollution Control Administration. Olives have been stored since harvest in salt brine reclaimed by passage through an activated carbon column. Although only half the normal storage period has passed, the olives are in satisfactory condition at present. Carbon treatment does not, however, remove a substantial amount of organic material from the brine. Further tests will be needed to determine how many times the brine can be reused. Meanwhile, dialysis and reverse osmosis are being investigated for removal of organics from the brine; present indications are that 75- 80% removal is feasible.

SUPPORTED BY U.S. Dept. of Agriculture

2.1164, A STUDY OF THE REMOVAL OF CARBONACEOUS, NITROGENOUS AND PHOSPHORUS MATERIALS FROM CONCENTRATED PROCESS WASTE STREAMS
H.F. LUDWIG, Engineering Science Inc., *Arcadia, California* 91006

This work is a laboratory evaluation of potential digester supernatant treatment processes. The study will include the characterization of process waste streams, the summarization and assessment of treatment technology and design and performance criteria for components of a treatment system.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1165, REDUCTION OF SALT CONTENT OF FOOD PROCESSING LIQUID WASTE EFFLUENT
J.W. RALLS, Natl. Canners Association, *Berkeley, California* 94710

1. Modification of an existing pilot ion-exchange unit from operation with brackish water to operation with olive processing waters. 2. Operation of the unit at a rate equivalent to 10,000 gallons of effluent per day while the effects in changes in influent composition on the unit performance are evaluated. 3. Investigation of the following variation in influent composition; salt content, pH, organic content, and suspended solids content. 4. Investigation of the effect of operation at different influent flow rates on the composition of purified column effluent and regeneration requirements. Investigate the highest sodium chloride concentration attainable in the regenerant effluent. 5. Operation for a sufficiently long period of continous use to develop cost factors for scale-up design. 6. Preparation of a comprehensive final report.

Project will initiate in fiscal 1970 and terminate in fiscal 1971. Current Project Period: January 1, 1970 to December 31, 1970.

2.1166, DRY CAUSTIC PEELING OF TREE FRUIT TO REDUCE LIQUID WASTE VOLUME AND STRENGTH
J.W. RALLS, Natl. Canners Association, *Berkeley, California* 94710

1. To fabricate demonstration scale peel removing equipment for caustic treated apricots, peaches and pears. 2. To install the equipment in a commercial fruit cannery. 3. To make modifications to commercial scale equipment used to treat tree fruit with sodium hydroxide solutions which will provide material for testing and developing the peel removal equipment. 4. To determine the most useful operational conditions for peel removal from apricots, peaches and pears. 5. To evaluate the quality of dry-caustic peeled tree fruit in experimental packs of unfinished product. 6. To determine the changes in COD and suspended solids content of rinse waters and clean-up waters from dry-caustic peeling of tree fruit. 7. To determine the final product yield increase resulting from the use of dry-caustic peeling of tree fruit. 8. To develop sufficient operational experience with dry-caustic peeling of tree-fruit to design a full-scale commercial unit.

Project will initiate in fiscal 1970 and terminate in fiscal 1971: Current Project Period March 30, 1970 to December 31, 1970.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1167, ENTERIC VIRUS REMOVAL FROM SEWAGE STABILIZATION PONDS
R.C. COOPER, Univ. of California, School of Public Health, *Berkeley, California* 94720

In this study, it is proposed to investigate the ability of stabilization pond treatment systems to remove enteric viruses from sewage.

Studies will involve the determination of the mechanisms and the degree and rate of virus removal in laboratory model, pilot, and full- scale pond treatment systems. Virus removal efficiency will be related to the overall efficiency of the pond treatment systems as measured in terms of various treatment parameters.

It is believed that the determination of the mechanisms and the efficiency of enteric virus removal by sewage stabilization ponds will be a significant contribution to the evaluation of the potential hazard of virus transmission by water reclaimed from sewage.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.1168, REMOVAL OF OIL FROM AQUEOUS WASTES BY FLOTATION

S.L. GOREN, Univ. of California, School of Chemistry, *Berkeley, California* 94720

A number of aqueous wastes carry micron and submicron droplets of emulsified oils which may affect the quality of the water into which these wastes are discharged. The proposed research is a theoretical and experimental study of air flotation applied to the removal of emulsified oils from aqueous waste. The objectives are to gain understanding of the mechanisms involved in flotation and to establish the degree and rate of clarification as functions of droplet size, bubble size, fluid and surface properties, chemical environment and other relevant parameters. Such information is necessary for the rational design and scale-up of air flotation devices for use in the treatment of aqueous wastes either alone or in combination with other treatment procedures.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1169, FILTRATION OF AQUEOUS EFFLUENTS CARRYING EMULSIFIED OILS

S.L. GOREN, Univ. of California, Graduate School, *Berkeley, California* 94720

A number of aqueous wastes carry micron and submicron droplets of emulsified oils which may affect the quality of the water into which these wastes are discharged. A promising method of separating such emulsions cheaply and throughly is to promote coalescence of the dispersed phase by passing the stream through a fibrous mat.

We are studying the coalescence of aqueous emulsions by fibrous media with the aim of elucidating the mechanisms involved and establishing the effectiveness of coalescence as a function of such variables as drop size, fiber size, mat geometry, fluid and surface properties, flow rate, etc. Our previous work has emphasized hydrodynamic factors. Current emphasis is on the role of the chemical composition of the stream, especially electrolyte type and concentration, which control double layer repulsive forces opposing coalescence. Emulsions well characterized as to drop size are passed through mats made from uniform diameter fibers, and the extent of coalescence is determined from measurements of turbidity and/or drop size distributions made with a Coulter counter before and after the mats. Pressure drop is also measured.

In addition to the purification of aqueous wastes containing emulsified oils, some of the results may be of importance in the filtration of solid wastes and in the improvement of water quality by percolation through soils.

SUPPORTED BY University of California - Berkeley, Cal.

2.1170, KINETICS OF ALGAL SYSTEMS IN WASTE TREATMENT

W.J. OSWALD, Univ. of California, School of Engineering, *Berkeley, California* 94720

The objectives of this research are: (1) To study the kinetics of algal and algal-bacterial symbiotics systems in biological waste treatment in relation to variables of substrate concentration (primarily, carbon nitrogen, and phosphorus sources), light exposure, cell concentrations, and applied turbulence on both a laboratory and on an outdoor pilot plant scale. (2) To develop a kinetic model that would incorporate the above variables, and make it possible to establish design parameters with which can be made the rational evaluation and prediction needed in utilizing algal and algal-bacterial systems in biological waste treatment, i.e., in primary, secondary, and tertiary (algae nutrient removal) waste water treatment. (3) Using the kinetic approach, to rationally develop criteria and parameters for use in the design of systems for accomplishing maximum removal of nutrients through assimilation by algae or algal-bacterial biomasses and bringing about maximum photosynthetic production of oxygen, thereby increasing the efficiency of the system, and hence reducing their areal and volumetric requiremets in practical applications. (4) Finally, through the development of a rational kinetic model for algal systems, (a) to provide a basis for a more adequate exchange and a clearer interpretation of data on waste treatment and field studies involving such systems than is presently possible, and (b) to arrive at a common denominator in the exchange of information with other scientific groups engaged in studies on systems involving algae.

2.1171, DRAIN DESIGN FOR NITRATE REDUCTION IN GROUND WATER

L.S. WILLARDSON, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Brawley, California* 92227

Research at the Southwestern Irrigation Field Station of the Agricultural Research Service in the Imperial Valley of California has shown that natural processes in the soil may be used to remove nitrates from ground water by reduction to nitrogen gas. More research information is needed on the degree and process of removal of nitrates from ground water moving into subsurface drainage systems. Research has also shown that soil conditions related to the reduction of nitrates are also related to iron and manganese clogging of tile drains. This study is undertaken with the following objectives: (1) to determine the effect of tile line submergence on the reduction of nitrate-nitrogen in ground water; (2) to determine the effect of surface application of organic matter on nitrate in ground water; (3) to determine the effect of tile drain submergence and surface application of organic matter on the movement of soluble iron and manganese in the soil.

On a full scale drainage system located in the San Joaquin Valley near Firebaugh, California, sampling equipment will be installed which will take moisture samples from the soil above and below the water table and in the vicinity of the drains. Platinum electrodes will be installed to measure redox potential throughout the soil. Soil samples will be obtained at various times to determine changes due to treatments. Tile lines for draining the field will be installed at various depths so that they can be submerged.

From water samples obtained from the tile lines and the soil, destruction of nitrates by natural conditions in the soil will be determined. The movement of iron and manganese in the soil toward the tile lines will be determined from the samples.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.1172, A STUDY OF A PROCESS FOR PHOSPHATE REMOVAL FROM WATER SUPPLIES USING LANTHANUM PRECIPITATION

H.L. RECHT, North Amer. Rockwell Corp., *Canoga Park, California* 91304

A laboratory investigation of the steps of a new process for phosphate removal from waste water will be performed. This process involves lanthanum precipitation of the phosphate followed by an alkali lanthanum recovery cycle. The purpose of the proposed program is to assess the technical feasibility of the process.

The speed and completeness of phosphate removal, and of each of the other process steps, as well as the extent of lanthanum and other reagent losses, will be determined parametrically in batch laboratory test using both pure solutions and sample water obtained from local treatment plants. From the results of the laboratory investigation, the technical feasibility of the process and an initial estimate of possible process economics may be determined. The results will also serve as a basis for design of an integrated laboratory process demonstration unit, which in turn would provide design data for an actual process demonstration pilot plant.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1173, PARAMETRIC STUDY OF THE KINETICS OF PRECIPITATION AND NATURE OF THE PRECIPITATE OBTAINED IN PHOSPHATE REMOVAL USING IRON AND ALUMINUM SALT

H.L. RECHT, North Amer. Rockwell Corp., *Canoga Park, California* 91304

2. WATER QUALITY

The rate of precipitate formation and the physical nature, chemical composition, and solubility of precipitates of phosphate with iron and aluminum under various conditions encountered in wastewater treatment will be investigated. Parameters to be studied include phosphate composition and concentration; pH; T.D.S.; precipitate formation; and stand time, temperature, and degree of agitation of solution during precipitate formation. Tests will be performed on pure solutions, synthetic wastewater effluents, and with secondary effluent. Results of experimental work will be used to explain the difference between predicted theoretical phosphate removals and actual removals, to identify and explain the mode of action of wastewater components contributing to the difference, and to suggest improved techniques for obtaining more complete phosphate removal by these chemical precipitation methods.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1174, ROLE OF SOLIDS IN COMBINED SEWAGE POLLUTION

D.L. FEUERSTEIN, Aerojet General Corporation, *El Monte, California* 91734

The program will establish the characteristics of combined sewage that are of significance with respect to solids separation operations and will investigate the feasibility of applying these operations for reduction of pollution from combined sewage overflows. The program consists of the collection and analysis of representative samples from the heterogeneous combined sewage and the conduct of laboratory studies to assess the impact of solids on disinfection practices. Sampling methods provide for determination of gross particle size distribution by screens in situ; thus actual effects of screening on particle coalescence and disintegration, solids separation and retention, and flow disturbance will be integrated into the results.

The sampling program will be performed in San Francisco, Calif.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1175, RENOVATION OF MUNICIPAL WASTEWATER BY REVERSE OSMOSIS SYSTEMS

D.L. FEUERSTEIN, Aerojet General Corporation, *El Monte, California* 91734

To perform laboratory-scale investigations to enhance and extend existing knowledge of the reverse osmosis process to waste water renovation applications and to determine operating parameters and relations required for system evaluation and optimization, as set out herein.

Laboratory-scale studies shall be performed using several grades of municipal waste water representing a broad spectrum of effluent qualities.

Except where noted and where necessary to the conduct of this program, flat membrane tests cells shall be utilized.

The laboratory-scale studies shall consist of three separate series of tests designed to elucidate and quantify for the reverse osmosis process the general performance, the effect of suspended solids on performance, and the membrane degradation by suspect compounds.

A mathematical model will also be developed to express the effect of above variables on process performance.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1176, NUTRIENT REMOVAL FROM AGRICULTURAL WASTE WATER

L.A. BECK, State Dept. of Water Resources, *Fresno, California* 93723

The project objective is to develop a practical biological treatment method for the removal of nutrients, essentially nitrate nitrogen, from agricultural subsurface drainage waters. The method of treatment that is being investigated is algal biomass production and harvesting. The nutrients are converted into algal cell material and removed with the cells.

Pilot scale growth units are being operated to optimize the parameters that affect algal growth. The parameters under investigation are nutrient addition, depth, detention time, mixing and climatic conditions.

Pilot scale separation units are being operated to determine the efficiency and economy of various harvesting techniques.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1177, EFFECT OF PHOSPHORUS REMOVAL PROCESSES ON ALGAL GROWTH

J.W. SCHERFIG, Univ. of California, School of Engineering, *Irvine, California* 92664

Increasing eutrophication of surface waters combined with a growing need for recreational water areas necessitate greater concern for removal of biostimulants including the classic nutrients from treated waste water. Major emphasis has been on methods for reducing the phosphorus and nitrogen content in effluents by combinations of chemical and biological processes.

There is however, little scientific evidence indicating that the efficiency of a treatment process in terms of the removal of biostimulants, can be measured only by the degree of phosphorus or nitrogen removal. Organic compounds acting as growth stimulants (such as vitamins) may be produced in significant quantities in traditional biological waste treatment processes.

Because of the complex and little understood phenomena related to algae blooms, the efficiency of current and proposed phosphate removal processes must be evaluated with respect to the removal of all biostimulants. The research proposed will seek to evaluate the individual steps in a sequence of treatment processes on the direct basis of algal growth in their effluents. It is believed that such information will provide a more rational basis for design of waste water treatment plants.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1178, A STUDY OF THE EFFECT OF ULTRASONIC ENERGY ON WASTE WATER

R. ROD, Amer. Process Equipment Corp., *Los Angeles, California* 90045

To prepare a report covering a study of the effect of ultrasonic energy on three characteristics of waste water, namely; disinfection, ammonia nitrogen content and refractory organic content. In each of the three areas of interest, the feed water shall be processed through two different air-operated ultrasonic atomizers, one operating at 50 KHz and the other at 100 KHz. In addition, an ultrasonic atomizing nozzle energized by an electro-restrictive transdoer-horn assembly operating at a frequency of 20 KHz shall be evaluated.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1179, ANTELOPE VALLEY WASTE WATER RECLAMATION FACILITY

J.A. LAMBIE, Los Angeles Co. Government, *Los Angeles, California*

The objective of this project is to demonstrate how waste waters can be reclaimed and utilized for agricultural, industrial, and aquatic recreational purposes. Tertiary treatment facilities will be used to produce the desired quality of effluent. These facilities will include oxidation ponds, chemical treatment, flocculation, clarification and filtration.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1180, TERTIARY TREATMENT IN THE PURIFICATION OF WASTE WATER

A.F. BUSH, Univ. of California, School of Engineering, *Los Angeles, California* 90024

Tertiary treatment process using trickling filter and clay coagulation to remove nitrates, phosphates, and biological contaminants from waste water is recommended in order to improve the prospects for wide use of reclaimed supplies.

As population density increases waste disposal must be oriented toward cleaner water with eventual use of reclaimed water rather than disposal.

Modern sewage treatment, like the septic tank, has duplicated many of the natural processes of waste stabilization. The aerobic conditions in the trickling filter and activated sludge systems have improved the process of biodegradation and effec-

tively destroyed the proteins, carbohydrates and fats. The water is then disposed of on spreading grounds, or into stream or oceans.

One of the advantages of soil percolation is that the water is purified by passing through it. The question arises whether a system can be developed which will produce all the results of the natural soil in a water purification process. It is a well established fact that clay in the soil profile removes phosphate and detergent.

It is now proposed that such results might be produced or closely approximated by a sequence of steps in which the trickling filter, followed by clay and alum flocculation unit and sand filter becomes the tertiary step following the algae pond (which in turn follows the activated sludge treatment).

2.1181, EDDY DIFFUSION AND BACTERIAL REDUCTION IN WASTE FIELDS

J.E. FOXWORTHY, Univ. of Southern California, Allan Hancock Foundation, *Los Angeles, California* 90007

The principal objectives of the proposed work are: 1. To further demonstrate the applicability of previously proposed continuous volume source diffusion models to the dispersion of conservation tracer dye and bacteria within surface waste fields in the sea. 2. To ascertain the effect of the type of submarine outfall on the rate of dispersion of tracer dye and bacteria. 3. To determine, under field conditions, the rates of disappearance of coliform and Fecal Streptococcal Group bacteria. 4. To investigate the effect of vertical mixing combined with radiant energy (sunlight) on bacterial disappearance in surface waste fields.

2.1183, FURTHER STUDIES OF INFILTRATION

J.B. FRANZINI, Stanford University, School of Engineering, *Palo Alto, California* 94305

Several aspects of unsteady and unsaturated flow in soils are under analytic and experimental investigation. Numerical procedures for analyzing moisture movement in soils have been developed for both one- dimensional and two-dimensional flow. The impedance of infiltration by pressure build-up of trapped air has been investigated. The effect of an applied pressure on horizontal flow in soils has been examined.

Future work will include an investigation of two-dimensional flow with a variety of impermeable barrier configurations. This work should lead to a better understanding of soil moisture movement which has many important applications such as: infiltration and its effect on runoff, the operation of underground drainage fields, the disposal of waste water through surface spreading, groundwater recharge, and other environmental problems.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1184, NITRIFICATION AT LOW TEMPERATURE

P.L. MCCARTY, Stanford University, School of Engineering, *Palo Alto, California* 94305

The object of this proposal is to develop a process for the efficient nitrification of effluents from municipal wastewater treatment plants. This is a necessary first step in the biological removal of ammonia nitrogen which may result in eutrophication, or excessive oxygen demand in receiving waters. The proposed process, termed the submerged filter, is to operate at wastewater temperatures from 5 degrees to 25 degrees C. The system has demonstrated effectiveness for efficient biological solids capture, especially where biological solids production is low and long generation times are encountered. Waste oxygenation using pure oxygen or other efficient methods of aeration will be required. The study will determine required detention times and operating procedures for efficient operations.

This project will begin on June 1, 1970 and is expected to be completed on May 31, 1972.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1185, MYCOLOGICAL PHENOMENA IN SEWAGE SPREADING BASINS

J.E. MCKEE, Calif. Inst. of Technology, Graduate School, *Pasadena, California* 91109

It is the general objective of this project to investigate the occurrence, concentration, and significance of various species of fungi in a well-ripened soil system that has been, and will continue to be, dosed daily with two feet of highly oxidized effluent from an activated- sludge plant handling municipal wastewater. Within this general objective, it is a specific aim to determine the role of major fungal species in biochemical degradation. Insofar as possible, reaction rates as well as pathways will be investigated. Special attention will be given to synergism among fungi and bacteria.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1186, BIOLOGICAL REMOVAL OF NITRATE ION ON BEDS OF ACTIVATED CARBON OR SAND

A.N. MASSE, Los Angeles Co. San. Dist. 21, *Pomona, California*

It has been discovered that denitrifying bacteria can be made to flourish on beds of granular media and that these bacteria can reduce the oxidized inorganic nitrogen forms to gaseous nitrogen. Methanol is added to the feed stream to serve as a food source to the bacteria. About 1 milligram of nitrate-nitrogen is reduced by 2 milligrams of methanol. NO3-N can be reduced to less than 1 mg/l by addition of the proper amount of methanol. Studies have been underway using both activated carbon and sand as the media. Contact times less than 10 minutes have proven adequate. The media must be backwashed frequently, but backwashing does not disturb the denitrifying properties of the media. Other studies are in progress to determine the suitability of waste products in place of the methanol.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1187, EXTENDED AERATION WASTEWATER TREATMENT SYSTEM FOR NAVAL ADVANCED BASES

J.P. COSENZA, U.S. Navy, Civil Engineering Lab., *Port Hueneme, California*

Technical Objective: Develop a packaged sewage treatment system that has the capability to effectively and economically treat all wastewaters from a 1,000-man naval advanced base. This development will provide improved wastewater treatment facilities in the ABFC (Advanced Base Functional Component) system.

SUPPORTED BY U.S. Dept. of Defense - Navy

2.1188, VACUUM WASTEWATER COLLECTION SYSTEMS FOR NAVAL ADVANCED BASES

C.R. HOFFMAN, U.S. Navy, Civil Engineering Lab., *Port Hueneme, California*

Technical Objective: Develop a vacuum waste water collection system for worldwide naval advanced base application.

SUPPORTED BY U.S. Dept. of Defense - Navy

2.1189, ECOLOGICAL AND PHYSIOLOGICAL IMPLICATIONS OF GREENBELT IRRIGATION

J.R. GOODIN, Univ. of California, School of Agriculture, *Riverside, California* 92502

The proposed research involves utilization of reclaimed municipal sewage effluent to irrigate a greenbelt for fire protection, recreation, groundwater recharge, improved wildlife habitat, and

increased forage production for livestock. The ecological and physiological implications of applying unusual quantities of water and nutrients to Mediterranean- type vegetation in attempting to bring about these benefits will be a prime consideration.

The Maloney Canyon project area is located near Lake Arrowhead in the San Bernardino Mountains. Reclaimed sewage effluent goes through final settling in basins located at the upper level of the project area. We propose to construct an irrigation system, experimental in design, with a main line extending approximately two miles from the effluent ponds along natural contours so that all water flow will be gravitational. Gate valves along this main will control individual replications for irrigation treatments, allowing the application of 1, 2, and 4 inches of supplementary water each week.

In addition to ecological changes brought about by the new environment, we propose to study the imposition of this changed environment upon introduced grasses, trees, and shrubs which may have fire protection, recreational, and wildlife value.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1190, TREATMENT OF PEAK WET WEATHER WASTEWATER FLOWS, AND RATE CONTROL OF ALL WASTEWATER DISCHARGES TO INTERCEPTOR SEWERS
J.A. VOEGTLE, Rohnert Park City Government, *Rohnert Park, California* 94928

Problem - The abandonment of existing wastewater treatment facilities and their connection to regional facilities is often economically infeasible due to the high cost of large interceptors. The problem is aggravated for combined collection systems or systems with excessive infiltration. The problem of treating peak wet flow at the regional facility is also perpetuated unless upstream remedial action is taken.

Plan of procedure - It is proposed that by utilizing a sedimentation - surge facility at the local plant, the underflow, throughout the year, can be controlled to discharge to the interceptor sewer at a rate slightly in excess of average dry weather flow. Existing plant facilities may be utilized as storage and treatment facilities for peak wet weather flow rate.

Techniques and Special materials - It is proposed that a sedimentation basin of broad dimensions (earth embankments with lining) be designed utilizing a hydraulic system of sludge and scum collection, to provide the controlled underflow rate at periods of peak wet weather flow. At normal flow rate the sedimentation basin (provided with aeration) can act as a conventional flow equalization (surge) facility.

2.1192, ECONOMIC AND INSTITUTIONAL ANALYSIS OF A WASTE WATER RECLAMATION AND REUSE PROJECT
H.O. BANKS, Leeds Hill & Jewett Inc., *San Francisco, California* (C-1912)

The objectives of the investigation are to develop concepts and methodology for the economic and financial evaluation of waste water reclamation and reuse as a source of supplemental water supply; to evaluate the financial impact of reclamation on the waste disposal system and to formulate the institutional arrangements necessary to make a reclamation and reuse system work.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1193, BOD, SOLIDS AND NUTRIENT REMOVAL FROM SECONDARY EFFLUENT BY FOAM FRACTIONATION
F. BELICK, San Jose City Government, *San Jose, California*

The objective of this project is to demonstrate the effective removal of secondary effluent solids, Biochemical Oxygen Demand, and nutrients such as nitrates and phosphates by a Foam Fractionation System, to be located at the San Jose - Santa Clara Water Pollution Control Plant. The aim is also to determine full-scale design and operating criteria in order to comply with required BOD and solids reduction and to attain optimum phosphate and nitrate removal. The successful demonstration of the System will provide one of the first systems that will economically remove solids; BOD, and nutrients from a waste water facility in one continuous process. Such a system would be applicable to a wide range of waste discharge volumes.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1194, THE IMPACT OF MUNICIPAL SEWERAGE CHARGES
J.A. JOHNSON, Mcmaster University, *Hamilton, Ontario, Canada*

The chief objective of the study is to describe the consequences of employing different types of sewerage charges. The study is divided into four parts. In part one the current position of sewerage charges are described. This description will be based on an analysis of mail questionnaires completed by approximately 2,000 municipalities. The relationship between size of municipality and factors like types of charge, proportion of sewerage costs covered, and proportion of businesses included in the sewerage system will be given special attention. The second part of the study is an evaluation of sewerage charges according to generally accepted tax criteria. The third part of study attempts to estimate the costs to various industries of employing different charges. This involves allocating costs under different sewerage formulas, among the industrial, commerical and residential categories and then within the industrial category. In part four, the impact of sewerage changes on industrial waste practices is investigated. An attempt is made to measure the responsiveness of business to different types of changes.

2.1195, WATER TREATMENT BY REVERSE OSMOSIS METHOD
A. PAKALNINS, Mcgill University, School of Engineering, *Montreal, Quebec, Canada*

(a) Proposed Research: To develop 1. a membrane with high yield characteristics, suitable for fresh water treatment; 2. a water treatment unit on a pilot plant scale.

(b) Objective: To investigate the technical and economic aspects of such a unit; and its applicability to reclamation and waste treatment.

SUPPORTED BY Canadian Government - Ottawa

2.1196, ECONOMIC FEASIBILITY OF PRODUCING DEPOLLUTANTS FROM AGRICULTURAL & INDUSTRIAL WASTE PRODUCTS TO USE IN WATER PURIFICATION (ABBREV)
J.W. PARLOUR, Univ. of Manitoba, *Winnipeg, Manitoba, Canada*

It would seem that a significant contribution to the conservation of water quality could be made by research into means whereby certain waste products (agricultural and industrial) might be utilized to provide a product or products which could in turn be employed in reducing present and future levels of water pollution.

Research is at present in progress in the Department of Food Science, University of Manitoba, under the direction of Dr. R. A. Gallop to investigate the conversion of certain agricultural solid wastes such as fibrous residues from grains, oilseeds, and food processing crops (e.g. cull potatoes) into potentially useful forms of activated charcoal. The possible conversion of waste paper, cardboard and other materials into this product is also being considered.

Activated charcoal is an extremely efficient de-pollutant and is essentially permanent in that it can be recycled with only a marginal loss of potency at each 'regeneration'. One of the possible future uses of this product which this study could investigate would be the efficient filtration of human and industrial effluent which might otherwise enter and pollute natural water resources, i.e. lakes and rivers, and underground water supplies.

Any large scale projects for the possible future production of de- pollutants from waste products must be based upon estimates of (1) likely costs of collection and processing of waste products and the actual costs of production, and (2) the benefits which might result from both the removal of waste products to produce a useful product and the employment of this product in subsequent reduction of environmental contamination as a result of large scale applications of the product.

It is recognized that the removal of certain waste products and their subsequent conversion to useful (but not necessarily economically profitable) products which can find application in the reduction of pollution may have definite social benefits which may not be readily defined in terms of dollars and cents. These social costs and benefits will also have to be considered in any evaluation procedure.

SUPPORTED BY University of Manitoba

2.1197, EVALUATION OF TREATMENT FOR URBAN WASTEWATER REUSE

K.D. LINSTEDT, Univ. of Colorado, School of Engineering, *Boulder, Colorado* 80302

The idea of renovation of wastewater for direct reuse applications has recently become of great interest to officials in the City of Denver. This interest has developed in large part because of the high cost associated with water development by transmountain diversion as it is practiced in this area. The successive use of water in the Denver Metropolitan area offers a method of significantly extending the available appropriated supplies.

The objective of the proposed project is to utilize the pilot plant developed in the first phase of this study to evaluate the technical feasibility of several treatment processes for renovating secondary effluent from the Metro Denver Sewage Treatment Plant. Specifically, efficiency data will be developed on the processes of biological nitrification, wastewater coagulation, and filtration as they are affected by variations in wastewater characteristics. The quality and cost data collected in this study will be useful in defining economic uses for renovated wastewater from the Metro Denver Waste Treatment Plant.

The project commenced June 1, 1969 and is planned for completion May 31, 1972.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1198, PRACTICALITY OF CHLORINATING ALGAE-LADEN EFFLUENTS FROM STABILIZATION PONDS

S.E. SCHULTZ, U.S. Air Force, Frank J. Seiler Res. Lab., *Colorado Springs, Colorado* 80840

Technical Objective: AF function - environmental support of base operations (sewage treatment). Deficiency - means of disinfecting sewage stabilization ponds having high organic loading at air bases required by the Air Mobility Plan. Research - determine the disinfecting power of chlorine and its compounds in algae-laden sewage pond effluents. How research contributes - establishes criteria for disinfecting pond effluent by chlorination and establishes testing procedures to measure the effectiveness of disinfection. The objective of this research is to investigate the effectiveness of chlorination for disinfecting algae-laden pond effluents prior to release. Existing techniques for determining the concentration of indicator organisms may require modification due to high algae content in effluent water. Results of the research will establish design criteria for disinfecting stabilization pond effluent by chlorination and establish testing procedures to measure the completeness of disinfection. This is required so the effluent of stabilization ponds may be released without hazard in areas where the Air Mobility Plan is in effect such as the sea environs.

2.1199, CONCENTRATION OF SUGAR BEET WASTES FOR ECONOMIC TREATMENT WITH BIOLOGICAL SYSTEMS

J.H. FISCHER, Beet Sugar Development Found., *Fort Collins, Colorado* 80521

The project is one phase of research to find an economic chemical or biological system to treat high volumes of sugar beet factory waste. One or more successful processes are necessary to satisfy effluent standards in States where sugar beets are processed.

The objective of the project is to concentrate sugar beet factory wastes by chemical precipitation and reuse of the decanted solution in a closed recirculation system. The excess water accumulated during the operation will be treated by anaerobic and/or aerobic processes to remove BOD prior to discharge. The bioactivity will be studied concurrently.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1200, NAVY ENVIRONMENT - THE MICROBIOLOGY OF THE MIDDLE SALT LAGOON AS RELATED TO SEWAGE DISPOSAL

W.L. BOYD, Colorado State University, School of Veterinary Medicine, *Fort Collins, Colorado* 80521 (N00014-67-A-0299-0015)

Technical Objective: Naval shore facilities, and in particular the Naval Arctic Research Laboratory, require knowledge of the effects of their sewage disposal on the environment in order to plan sewage treatment facilities most efficiently. The objective is to obtain and analyze biological data in order to assess the value of a large lagoon as a settling pond for sewage in the arctic environment.

SUPPORTED BY U.S. Dept. of Defense - Navy

2.1201, COMBINED COOLING AND BIO-TREATMENT OF BEET-SUGAR FACTORY CONDENSER WATER EFFLUENT

G.O. LOF, Colorado State University, Environmental Resources Center, *Fort Collins, Colorado* 80521

The objective is to establish the feasibility of reducing thermal and organic pollution from beet-sugar factories by cooling towers in a closed system in which biological oxidation of sugras and other organics is induced and maintained.

The primary procedure will be laboratory determination on actual and synthetic samples of beet-sugar condenser water effluents under various conditions of termperature, concentration, recirculation rate, separation of sludges, etc. After batch experiments have yielded the necessary data, a small-scale flow apparatus will be assembled and will be operated to determine the extent to which the primary data can be applied in practical design.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1202, THE MECHANISMS OF WASTE WATER TREATMENT AT LOW TEMPERATURE

S.M. MORRISON, Colorado State University, Environmental Resources Center, *Fort Collins, Colorado* 80521

The primary purpose of the study is to identify and evaluate the biological, chemical, and physical factors that affect waste water treatment in areas and communities with prolonged periods of low temperature. This information, unknown at present, is essential to provide the criteria for the ultimate objective of waste water treatment plant design for cities at higher altitude in Colorado, as well as cities at high latitudes of the United States.

2. WATER QUALITY

The study will consist of three phases: (a) the evaluation of the biological, chemical and physical factors, (b) laboratory bench top treatment systems, and (c) the development of design criteria to incorporate new information developed under (a) and (b).

Under Phase (a), the following studies will be initiated: 1) Isolation, identification, modification, and adaptation of sewage treatment microorganisms to the cold environment; 2) Determine the optimal microbial flora for waste digestion at temperatures between 0 degrees - minus 20 degrees C; 3) Modification of the waste water as a microbial substrate to provide optimal digestion rates; and 4) Determine action of chlorine or other final disinfectant agents on potential pathogens at low temperatures.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1203, WASTE WATER DISPOSAL SYSTEMS FOR DEVELOPING UNSEWERED AREAS

R. LAAK, Univ. of Connecticut, School of Engineering, *Storrs, Connecticut* 06268

The present septic tank leaching field or seepage bed method of waste water disposal restricts development in the State of Connecticut. New methods must be developed to increase septic tank leaching fields' service life.

It is proposed to develop a backwashable leaching field that can be cleaned in place and to provide improved drainage from the seepage bed with less land area than with current methods. In addition, the suitability of soil for leaching areas will be investigated in order to achieve greater reliability in predicting the soil's capacity to accept waste effluent.

The backwashable leaching field proposed consists of a synthetic fibre bag supported by a plastic corrugated wall. The moisture content of soils and their non-capillary pores appear to correlate to leaching field performance.

The project was started in 1970 and will be completed in 1972.

SUPPORTED BY Connecticut State Government

2.1204, AIR OXIDATION OF ORGANIC COMPOUNDS IN AQUEOUS SYSTEMS

D.W. SUNDSTROM, Univ. of Connecticut, School of Engineering, *Storrs, Connecticut* 06268

Organic compounds can be oxidized chemically in an aqueous system by heating under pressure in the presence of air. When applied to the disposal of aqueous wastes, the technique is referred to as wet oxidation. Under the usual operating conditions, the organic wastes are not completely destroyed during oxidation. The method is of particular interest since the wastes are removed by chemical rather than by biological action.

The purpose of the project is to determine the reaction kinetics of several organic compounds during wet oxidation. The rate and extent of oxidation of several organic compounds will be examined over a range of temperatures, pressures and concentrations. Since simultaneous mass transfer and chemical reaction occur during wet oxidation, the relative magnitudes of these rate processes will be established. Initial experiments will emphasize the destruction of an insoluble organic compound in a flow reactor. The results of this study should provide a better understanding of the wet oxidation process.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1205, INDIVIDUAL WASTE DISPOSAL SYSTEMS

W.C. WHEELER, Univ. of Connecticut, School of Agriculture, *Storrs, Connecticut* 06268

The objective of this study is to investigate oxygen and temperature levels in the disposal fields of individual septic systems and its effect on the over-all disposal system.

Experiments will be conducted to determine the effect of temperature and oxygen on the effluent leaving the septic tank with provisions to inject air into the drainage tile lines. The evaluation of these effects will be based upon field observations.

Both laboratory and field studies are planned. The field measurements will be made at selected locations in the state.

Instrumentation will include the use of multi-point recorders for temperature measurements, pH meter, dissolved oxygen analyzer, and the standard biological and sanitary engineering tests as an aid in the evaluation of the effluents of the tests.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1206, WATER QUALITY CONTROL WITH SYNTHETIC POLYMERIC FLOCCULANTS - EFFECT OF MG, CA, CU, & ZN IONS ON BACTERIA & ALGAE (ABBREV)

J.K. DIXON, Univ. of Connecticut, Graduate School, *Torrington, Connecticut* 06790

1. The control of the quality of water with synthetic polymeric flocculants has been studied in 1967-1968 and 1968-1969 under grants from the Institute. The practical value of these polymers for the flocculation of bacteria and algae has been investigated in detail, suggesting their use in flocculating, settling, and filtration of bacteria in sewage plant effluents and other polluted waters, as well as the treatment of inland lakes with polymeric flocculants for the removal of algal contamination. 2. The optimum characteristics of the polymers have been determined. Their molecular weights and ionic character has been somewhat established, and their effectiveness at different pH values has been examined. 3. The concentration of trace metals has been reported to be a factor in flocculation experiments with silica. It is proposed that Mg plus plus, Ca plus plus, Cu plus plus, and Zn plus plus be employed in varying concentrations in a study of the flocculation of algae and bacteria. The effect of these trace metals on the kinetics of flocculation would be studied at different pH values. 4. The results would be correlated with earlier work on flocculation of solids, including bacteria and algae, in sewage plant effluents, potable water supplies and other water systems, thus broadening basic understanding of the action and the practical application of synthetic polymers for water quality control.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1207, OILY WATER SEPARATOR

W. WILSON, A M F Incorporated, *Uncasville, Connecticut* 06382 (MA-4152)

Purpose: To develop an effective shipboard oil-water separation system as a means to prevent pollution of the seas by oil discharged with bilge and ballast water.

Description: A land-based pilot system was built and tested at the contractor's seawater test laboratory. Results were limited, and were significantly lower throughout than designed. The filters were modified to increase separation efficiency at higher flow rates.

Further investigations and tests examined effects of oil concentrations, oil viscosity, flow rates, differential pressure, temperature, and filter cleaning speed. It was found that oil concentration, mixture, flow rate and differential pressure across the filters are the major considerations in the separator development. A 600-800 gpm unit was designed during Phase II. Because of excessive physical size of the larger capacity unit, the 100 gpm laboratory system was packaged and final land-tested during Phase III to establish complete operating and performance characteristics.

The unit did not perform well when fed with finely dispersed oil but was effective, yet not totally satisfactory, when oil was injected downstream of the seawater circulation pump.

The contract expired 12-31-70. Final report will be available in September, 1971.

SUPPORTED BY U.S. Dept. of Commerce - Maritime Admin.

2.1208, TREATMENT OF BRASS MILL EFFLUENTS

O.P. CASE, Anaconda American Brass Co., *Waterbury, Connecticut* 06720

The brass industry is one of the principal industries in Connecticut affected by current efforts to reduce water pollution. Accordingly this project was undertaken on behalf of the whole industry. The project staff met regularly with an advisory committee made up of representatives from three other large brass companies.

The principal discharges requiring treatment are the spent pickle liquor and rinse water. Removal of dissolved copper is complicated by the presence of about the same concentration of chromium. In the process developed, the copper is removed by plating it out on scrap iron--so called 'cementation.' Then, the remaining liquid, which is highly acidic, is neutralized with lime causing the formation of a sludge. The sludge is removed in a clarifier and then partially dewatered in a centrifuge.

The variables affecting the efficiency of this process were studied in laboratory experiments and on a pilot plant basis. Parallel investigations were made of effluent sampling, copper recovery, oil removal and disposal, and the removal of carbon black from casting shop water. An effort was made to process the sludge into a product having intrinsic value, but no economically feasible process was found. The primary effluent resulting from the process was demonstrated as harmless to fish and the value of recovered copper represented a significant offset to the cost of the treatment.

The process for treating brass mill effluents developed in this project was described to representatives of brass companies from all over Connecticut at a special seminar held in October, 1969.

SUPPORTED BY Connecticut State Government

2.1209, INVESTIGATION OF AMPHIPATHIC WATER-SOLUBLE POLYMERS AS FLOCCULANTS AND FLOTATION AIDS IN DOMESTIC WASTEWATER TREATMENT
R.R. BROWN, Standard Brands Chem. Indus., *Dover, Delaware* 19901

New, commercially feasible, synthetic polyelectrolytes or nonionic polymers with improved flocculation ability for suspended matter in domestic wastewater will be synthesized and tested. The incorporation of surface active groups into the basic polymeric flocculant will be studied as a possible approach to enhancing the flocculating ability of polymers. Polymers will be analytically characterized as to composition, molecular weight, surface activity, charge type, density, and active group content for evaluation as flocculants and flotation aids in wastewater treatment.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1210, ROTATIONAL STABILITY IN DILUTE POLYMER SOLUTIONS
M.M. DENN, Univ. of Delaware, School of Engineering, *Newark, Delaware* 19711

The research is an investigation of the stability of rotation and parallel flow of dilute polymer solutions and the nature of resulting secondary motions. Theoretical and experimental studies suggest that the flow stability can be used as a means of determining rheological properties of systems too dilute for study by conventional measuring techniques. The ultimate goal is to obtain improved understanding of mechanisms of changes in mass and momentum transport in polymeric systems for application to one and two phase water treatment systems.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1211, THE CATALYTIC OXIDATION OF ORGANICS IN WASTEWATER
J.R. KATZER, Univ. of Delaware, School of Engineering, *Newark, Delaware* 19711

Many wastewater streams, particularly those originating in the chemical and petroleum industry, contain undesirable organic materials which degrade very slowly biologically and which thus must be removed from the water by other means. Catalytic oxidation, possibly preceded by a concentration step, represents a potential method of removing such materials which have not yet been studied. It is proposed to study the catalytic oxidation of organics in aqueous solution using phenol oxidation as a model reaction. The objective of the work is to determine the kinetics and mechanism of the catalytic phenol oxidation reaction in aqueous solution and thus to begin to develop a fundamental understanding of the mechanisms of reaction and modes of action of an oxidation catalyst in aqueous solution.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1212, ANAEROBIC TREATMENT OF STARCH WASTE-WATERS
G.P. RASMUSSEN, Univ. of Delaware, School of Engineering, *Newark, Delaware* 19711

The proposed research is a determination of the BOD and solids uptake of starch wastes on contact with digested solids, the subsequent concentration of the MLSS by sedimentation and flotationand finally a material balances and kinetics study of the concentrated starch waste digestion process.

The study would involve construction of both continuous batch fed, treatment processes consisting of a complete mixed contact stage, alternate sedimentation and flotation concentration stages and a final anaerobic digestion stabilization stage. In addition , the study will be conducted at various loading rates and detention times in order to assess the effect of these parameters upon treatment performance.

2.1213, ECONOMIC AND ENGINEERING ASPECTS OF WATER IN DELAWARE'S AGRI-BUSINESS INDUSTRY
R.C. SMITH, Univ. of Delaware, School of Agriculture, *Newark, Delaware* 19711

Delaware's agri-business industry is a major user of water. Wise and economic use of water for food processing and waste disposal requires long-range planning now for optimum development of water resources in the State.

Waste flow measurements and composite waste samples will be taken for vegetable and for poultry processing plants. The amount of recirculated water in each plant for each product will be estimated. The waste samples will be analyzed to determine the level of BOD COD, total suspended solids and pH.

Data will be obtained from each plant to determine the existing fixed and variable costs of water requirements, waste treatment and waste water disposal. The relationship between the cost of waste disposal, the method of disposal used and the level of waste in disposal water will be determined.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1214, ECONOMIC AND ENGINEERING ASPECTS OF WATER IN DELAWARE'S AGRI-BUSINESS INDUSTRY
R.C. SMITH, Univ. of Delaware, Agricultural Experiment Sta., *Newark, Delaware* 19711 (DEL00760)

OBJECTIVE: Determine the effect of product mix upon the level of waste and upon the efficiency of water utilization. Determine the gains that would accrue in the form of increased efficiency of water utilization and reduced waste flow per case from operating plants at maximum capacity rate.

APPROACH: Waste flow measurements and composite waste samples will be taken for vegetable and for poultry processing plants. The amount of recirculated water in each plant for each product will be estimated using the Bernouilli equation. Data will be obtained from each plant to determine the existing fixed and variable costs of water requirements, waste treatment and waste water disposal. These data will be analyzed to determine the level of waste associated with processing various products. The relationship between the cost of waste disposal, the method of disposal used and the level of waste in disposal water will be determined. The economics of recirculation of water will be determined.

PROGRESS: Water use and waste disposal data have been collected for Delaware poultry processing plants. Samples of waste water collected from various stations in the plants have been analyzed for BOD and COD. There is considerable variation in waste treatment by the various poultry plants. The level of BOD tends to vary from 400 to 1,000 parts per million in the main effluent from the plants. Several plants have added waste treatment facilities in order to reduce the strength of the waste as it enters a stream or municipal system.

2.1215, SORPTION BEHAVIOR OF ORGANIC PYROPOLYMERS IN AQUEOUS SOLUTION
S.D. BRUCK, Catholic University of America, School of Engineering, *Washington, District of Columbia* 20017

The investigation of the sorption behavior of organic pyropolymers is proposed with special reference to the removal of organic materials (including pesticides), radioactive substances and ions, such as NH4 plus, from secondary effluents. These pyropolymers can be readily prepared from commercially available heterocyclic/aromatic polyimides and, unlike activated carbons, are characterized by the presence of a large number of nitrogen and oxygen atoms, lesser quantities of hydrogen, and depending on the starting material, ionic groups. These properties, plus the fact that the microporosity of the pyropolymers can be altered by varying the preparative conditions and thermal treatment, make these systems attractive candidates for the study of the sorption- desorption processes and for the elucidation of the physico-chemical parameters that enhance these processes. Direct comparison will be possible between the sorption-desorption properties of the pyropolymers and those of activated carbons studied by other workers.

2.1216, STABILIZATION POND OPERATION IN TROPICAL AREAS
M.D. YOUNG, Gorgas Memorial Institute, *Washington, District of Columbia* 20006 (DADA17)

Technical Objective: Objective - to investigate and define - A. The roles of physical, chemical, and microbiological parameters in relation to operation of stabilization ponds in tropical areas with particular emphasis placed upon waste material, characteristics and loadings, dissolved oxygen, algae classification and production, and the relatively high intensity sunlight of tropical areas, B. The effects of various detention periods, water depths, and loading fluctuations upon the operation and performance of stabilization ponds in tropical areas, C. Maximum loading limits, in terms of 5-day, 20 degree C biochemical oxygen demand (BOD) in relation to design and operating parameters.

SUPPORTED BY U.S. Dept. of Defense - Army

2.1217, RECONDITIONING AND REUSE OF FOOD PROCESSING BRINES
W.A. MERCER, Natl. Canners Association, *Washington, District of Columbia* 20036

Briefly the proposal is to conduct a pilot scale study to determine the feasibility of re-using spent brines from storage and processing operations in olive packing by reconditioning the brine through a charcoal absorption and filtration column. The portable filter will be operated throughout the duration of the two year project at each of four locations in the California Central Valley area.

The supporting collection, reduction and analysis of data will be directed toward eliminating the present tie-in to municipal sewage system as well as lagoon systems used by olive processors and develop economic and effectiveness data for full scale development.

SUPPORTED BY U.S. Environ. Protect. Agency O.O.W.P

2.1218, INTEGRATED TREATMENT OF LIQUID WASTES FROM FOOD CANNING OPERATIONS
W.A. MERCER, Natl. Canners Association, *Washington, District of Columbia* 20036

The objectives of this proposal are as follows: (1) to determine the feasibility of employing a high rate trickling filter in the San Jose, California canning plant to treat strong organic wastes encountered in vegetable and fruit processing operations, which although low in volume (approx. 20% of total), contribute as much as 60% to the total BOD load. The filter will be 14 ft in diameter and 21.5 ft. high, employing synthetic media and operating in a range between 100 and 200 gpm. It will be subjected to variations in flow, pH control and nutrient addition to determine its optimum working parameters. (2) To determine the effectiveness of using an air flotation process with and without addition of flocculants in removing suspended solids prior to secondary treatment. (3) To evaluate the center discharge solids separation techniques and its effect on the total BOD content.

A study will also be made of the usage of edible acids as a bacteriostatic agent to prevent growth in recirculated flume water. Following the one year testing operation, it is proposed to select units to be incorporated in full scale plant operations for a further demonstration project. The reason for the low project cost is due to NCA already having on hand several pieces of equipment required to test these processes.

STATUS: Received worthwhile information on operation of units during last fall's processing operations. Will continue with evaluation of the various units this fall.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1219, IMPACT OF CHANGES IN TECHNOLOGY ON WATER USE
C. HOWE, Resources for the Future Inc., *Washington, District of Columbia* 20036

The objectives of the study is to determine the impact of future technological changes on water use. Alternative rates of water use by typical establishments in various sectors of the economy (e.g., residential, selected industrial, and agricultural) will be developed for several future dates as influenced by technological changes. This will be done under alternative assumptions regarding the incentives induced by (1) specific government policies (e.g., water quality standards, agricultural price policy, public water project reimbursement policy, etc.) and (2) incentives likely to occur independently of specific government policy.

Insofar as possible, water use rates will be specified in terms of rates of withdrawals, consumptive use and the disposal of water borne wastes.

The report on the investigation is nearing completion. The project was initiated in Fiscal Year 1969 and will be completed in fiscal year 1971.

SUPPORTED BY U.S. National Wtr. Comm. - Arlington, Va

2.1220, PRODUCTION OF WATER AND WASTEWATER TREATMENT EQUIPMENT
K.L. KOLLAR, U.S. Dept. of Commerce, Bureau of Domestic Commerce, *Washington, District of Columbia* 20230

Water Quality Management and Protection. A survey has been completed of some 180 manufacturing establishments engaged in the production of water and wastewater treatment equipment. The number and value of treatment equipment produced in 1968 and the production capacity for 24 major product categories will be published in a report 9/1970. Among the products the report will cover are chemical feed equipment, filtration equipment, sludge digestion and disposal equipment and package treatment plants.

SUPPORTED BY U.S. Dept. of Commerce - Bur. of Dom. Com.

2.1221, TERTIARY TREATMENT RESEARCH AT THE JOINT FWPCA DISTRICT OF COLUMBIA PILOT PLANT
D.F. BISHOP, U.S. Dist. of Columbia Govt., Dept. of Sanitary Engin., *Washington, District of Columbia*

The engineering research will provide design data and cost quality relationships for a combination of tertiary processes applied to the DC secondary influent. The research contributes to the engineering development of advanced waste treatment processes and specifically to the development of pollution control techniques for water sources such as the Potomac River. It includes evaluation of nutrient removal and wastewater renovation processes using the treatment series: chemical (lime, alum, or iron salts) clarification for phosphate and particulate removal, air

stripping for ammonia removal, pH controlled by decarbonation for removal of excess Ca , gravity filtration for final turbidity removal, granular carbon treatment for dissolved organic removal, and chlorination for product disinfection.

The pilot plant (100 gallons per day capacity) features automatic control systems which include measurement and control of: flow, pH conductivity, pressure and turbidity, and an automatic filter backwashing system. The filtration system also includes automatic differential pressure measurement through the length of filter media to permit evaluation of various media.

Chemical clarification is being evaluated first, with preliminary results: CaO dose - 250-350 mg/l; residual turbidity - 5-7 J.U.; residual phosphate - less than 0.5 mg/l.

The remaining processes will be added stepwise to the treatment series, following satisfactory development of the preceding processes.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1222, CHEMICAL SLUDGE DISPOSAL AND CHEMICAL RECOVERY AT THE JOINT FWPCA DISTRICT OF COLUMBIA PILOT PLANT

D.F. BISHOP, U.S. Dist. of Columbia Govt., Dept. of Sanitary Engin., *Washington, District of Columbia*

The research will provide engineering design data for the handling and disposal of chemical sludge products in the joint FWPCA District of Columbia tertiary treatment pilot plant. These sludges may include calcium carbonate, aluminum hydroxide, and ferric hydroxide sludges. It will also determine the feasibility of recalcining calcium carbonate sludges and removing lime for reuse in chemical clarification of wastewaters.

The research will contribute to the general development of techniques for ultimate disposal of sludge produced by advanced waste treatment process and specifically will attempt to improve the economics of lime clarification by recovery and reuse of the lime. The processes and the chemical sludge disposal system include sludge thickening, sludge dewatering (vacuum filtration, incineration and/or recalcination of the chemical sludge). The system features a pilot scale vacuum drum filter with continuous washing of the filter belt. Automatic weight of the dewatered sludge takes continuous feeding of cake to a 30-inch diameter, six-hearth furnace. The maximum furnace temperature is approximately 1900 degrees F with individual temperature control for each hearth.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1223, TREATMENT OF WATERCRAFT WASTES FROM SMALL VESSELS TO SHORE TREATMENT FACILITIES

H.G. QUASE, Underwater Storage Inc., *Washington, District of Columbia* 20036

The design, construction and operation of a pilot plant to show the feasibility of providing a facility for the collection, storage and disposal of waste from recreational watercraft.

An on-board holding tank was installed in each of ten boats for total impoundment of all effluent and for the connection to a dockside sewage collection system through a quick-connect coupling. Each boat is provided with a pump, tank and macerator. At dockside, each boat will pump directly into a piped collection system.

The dockside collection system is installed with a flexible hose connector at each ship for attachment to the respective boat. The collection system is installed for gravity flow to an underwater storage tank fabricated of synthetic rubber, impregnated with nylon fibers and fastened to the river bed by a system of patented anchors. The underwater storage tank will receive and hold the effluent for periodic discharge by an onshore pump station to sewage trucks for delivery to a sewage plant.

Flow meters are provided for recording daily and weekly waste flow. Samples of waste material leaving underwater storage tank are taken for laboratory analysis.

The facility will demonstrate that by the storage of watercraft waste, both on board and at dockside, discharge of sewage from boats into rivers will be eliminated.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1224, WATER RESOURCE PLANNING IN URBAN REDEVELOPMENT

B.J. WACHTER, Water Pollution Res. & Appl., *Washington, District of Columbia* 20036

The needs for integration of efforts in water resource planning have been clearly stated. The proposed research will explore the extent to which this integration occurs in planning water resources facilities in Urban redevelopment areas.

Step 1 - The determination of how urban redevelopment in the southwest District of Washington, D.C. has affected the patterns of water use and wastewater disposal and the basis by which these changes were anticipated in the design for water and sewer utility rennovation.

Step 2 - Analysis of the extent to which water resource planning was integrated with redevelopment plans - the timing, mechanics and institutional considerations involved in coordinating plans with agencies responsible for water supply, storm drainage, sewage disposal and pollution control.

Step 3 - Determination of the relationship between information developed in (1) and (2) with comparable data from a minimum of ten other redevelopment projects in other cities.

Step 4 - The development of a manual of guidelines for consideration in water resource planning as it applies to urban redevelopment.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1225, REVERSE OSMOSIS DEVELOPMENT FOR ACID MINE DRAINAGE CONVERSION

L.W. WEINBERGER, Zurn Environmental Engineers, *Washington, District of Columbia* 20037

The overall objective of this program is to determine the technical feasibility and economics of employing a reverse osmosis process for conversion of acid mine drainage to municipal and industrial water supplies. Primary emphasis in this program will be placed on field evaluations of reverse osmosis pilot plants and associated pretreatment equipment to develop design, operation and economic data for multimillion gallons per day acid mine conversion reverse osmosis plants.

The contractor will provide facilities, personnel and materials to conduct a field evaluation of reverse osmosis process for conversion of acid mine drainage to municipal and industrial water supplies. The program will be performed in three phases. The work will include, but not be limited to the following: (1) Phase I - Field Evaluation Tests at Norton, West Virginia - Analyze the field test data obtained under previous OSW contracts with the Fulf General Atomic 10,000 gpd spiral design reverse osmosis unit on acid mine drainage waters and determine alternate modes of equipment operation to obtain over 95% product recovery. (2) Phase II - Field Evaluation Test At Another OSW Designate - Operate the test equipment at the second site to verify the applicability of the operating parameters determined to be the most economic optimum at Norton, West Virginia. (3) Phase III - Preparation Of Cost Estimates - Based on information obtained in Phases I and II, prepare capital and operating cost estimates for conversion of acid mine drainage waters to municipal and industrial water supplies.

2.1227, SYSTEMS FOR TILE DRAIN SLUDGE CONTROL FOR CITRUS WITH HIGH WATER TABLE IN FLORIDA
D.V. CALVERT, Indian River Field Laboratory, *Fort Pierce, Florida* (FLA-RL-01478)

OBJECTIVE: Evaluate systems of soil modifications and tile installation in the prevention of sludging in tile drains. Evaluate the response of citrus rootstock-scion combinations to drainage systems and soil modifications. Develop prediction factors on drainage of flatwood soils.

APPROACH: This study is designed to evaluate some experimental soil management practices and drainage systems for preventing clogging of drain tiles in citrus groves planted on poorly drained soils. Twelve different citrus rootstock-scion combinations will be used as indicator plants for this evaluation. Three non-conventional grove practices will be tested singly and in various combinations: deep tillage and mixing of soil profile to a depth of 42 inches. Neutralization of the mixed soil profile with lime to a depth of 42 inches. Submergence of the tile drainage lines below the water table by maintaining water above the outlet ends of the tiles in the open perimeter ditch.

PROGRESS:

SUPPORTED BY Florida State Government - Tallahassee

2.1228, SYSTEMS FOR TILE DRAIN SLUDGE CONTROL FOR CITRUS WITH HIGH WATER TABLE IN FLORIDA
J.G. FISKELL, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-SL-01478)

OBJECTIVE: Evaluate selected systems of soil modification and tile installation for prevention of drain sludging and for growth of citrus rootstock-scions; predict drainage, sludge formation, and root viability in flatwood soils.

APPROACH: Modify acid, sandy flatwoods soils by profile mixing (42 in.) of spodic and clay layers, liming, and installation of tile drains with open and submerged outlets at 42 inches; grow six citrus rootstocks with two scion varieties on the area. Time-dependent observations of physical and chemical characteristics of soil and water will include sludge composition and formation, tile effluent flow and composition, three-dimensional distribution of soil-water potential, energy budget and water balance, and citrus rooting.

PROGRESS: Soil samples of pedons from the site for the field study at Fort Pierce were found to have most of the CEC and water-retention capacity in the spodic horizon and underlying clay. The spodic material was unusually dark, dense, and impermeable as well as highly acidic. Since deep mixing for tile drainage was to be a depth of 36 inches, it was calculated that 29 tons of lime were needed to maintain a pH above 6.5 for 20 years in the profile. This system for controlling sludging of tile drains is to be compared to deep mixing of acid soil and to shallow tillage. The equipment acquired within the department for this project has undergone tests. This included specific ion electrodes, continuous particle electrophoresis, and data acquisition system for the gamma-ray attenuation devices. Hydraulic conductivities and soil water characteristic curves were determined on undisturbed soil cores from pedons at the site.

SUPPORTED BY Florida State Government - Tallahassee

2.1229, SYSTEMS FOR TILE DRAIN SLUDGE CONTROL FOR CITRUS WITH HIGH WATER TABLE IN FLORIDA
J.M. MYERS, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-AG-01478)

OBJECTIVE: Measure the influence of sludge formation, drain efficiency and growth of citrus trees for submerged and vented outlets for subsurface drains.

APPROACH: Main plots will be 300 X 360 in size. Plots will be split into two parts and three drain lines 300 ft. in length and 60 ft. on centers will be installed in each split plot. Drain outlets from one half of the split plots will be submersed and the remainder will be vented to the atmosphere. Rate and time of outflow from the center line of each split plot will be measured and recorded. Measurements will be made to depth of water table for each of the drainage treatments. Response will also be measured in terms of chemical content of drain effluent, quantity of sludge formation, growth of plants, and fruit yield.

PROGRESS: Precipitation of ferrous sulfide sludge in and around drain lines in certain flatwood soils has rendered the drains ineffective in a relatively short period of time. Sustained economical citrus production on these soils is dependent upon effective profile drainage and water table control. Under this project, two approaches will be investigated as means of preventing the clogging of drain lines. One will be to neutralize the soil profile by mixing lime in the soil above the drain line. This should immobilize the iron in solution and greatly reduce its movement toward the drain lines. The other approach will be to install the drain lines in a manner that they must function below the water table. This will create an anerobic environment in and around the tile line. Under this regime, ferrous iron and sulfides will not be precipitated or oxidized and will leave the system in solution. A tract of land at the Indian River Field Laboratory is being developed for these and other studies relating to citrus production on flatwood soils. The perimeter ditch, dikes, roadways and part of the deep plowing - mixing has been completed. All other components of the experimental layout, with the exception of the irrigation system, have been designed. Construction on the facility will continue during the year. Tentatively planting time has been set for the fall of 1970.

2.1230, INDUSTRIAL COMPLEX OF AL KHARDJ
UNKNOWN, Sogreah, *Grenoble, France*

Construction of an installation for treatment of water from the industrial complex of Al Khardj. (flash evaporation, cooling, and demineralization by mobile bed exchange of ions.)

SUPPORTED BY Thomson Houston Company - Manurhin, Arabia

2.1231, IMPROVED EQUIPMENT AND OPERATING METHODS FOR POULTRY PROCESSING TO REDUCE WATER REQUIREMENTS
R.E. CHILDS, U.S. Dept. of Agriculture, Transportation & Facil. Div., *Athens, Georgia* 30604 (TF2-115A)

OBJECTIVE: Reduce quantity of water being used to process poultry through equipment and process modifications and redesign facilities to permit water reuse where potable quality is not required.

APPROACH: Determine water demand for principal processing steps in typical commercial plants. Redesign water dispensing and run-off facilities to permit a lower operating volume. Develop and test equipment for reconditioning water for reuse in operations that do not require potable quality. Prepare recommendations and guidelines for modifying equipment and process designs that reduce water use requirements without creating hazards to product quality and minimize facility and equipment modification.

PROGRESS: Investigations of water use rates were continued in selected case study poultry processing plants to determine the quantity of water used for various processes, pieces of equipment, and overall plant operation. Measuring devices and pressure gauges were installed on water supply lines to bird washers in three case study plants. Basic data collected on bird washers currently in use include bacteria counts before and after washing, water pickup in bird washer, and volume of water used at various pressure levels. An experimental bird washer that allows an infinite number of nozzle positions and pressure adjustments was designed and constructed. Interchanging various types and sizes of nozzles made possible the study of the effects of water pressure, water flow rates, and nozzle types and position on bacteria removal and water pickup of an eviscerated broiler carcass.

SUPPORTED BY U.S. Dept. of Agriculture

2.1232, MICROBIAL TRANSFORMATION OF POULTRY LITTER AND ITS RELATION TO WATER POLLUTION
J.E. GIDDENS, Univ. of Georgia, School of Agriculture, *Athens, Georgia* 30601

The proposed research plan involves laboratory, greenhouse and field investigations directed at determining how microbial changes in poultry litter may influence the pollution of ground and runoff water. The breakdown products of the litter, especially ammonia and nitrates and the relationship of ammonia to nitrifiers and coliform bacteria will be determined.

Laboratory investigation will include; (1) Determination of microbial population of poultry litter at various stages of decomposition. (2) Analysis for ammonia at various stages and relationship of changes in chemical properties, especially ammonia accumulation to changes in nitrifiers, coliform bacteria and others.

Field and greenhouse experiments will show the effect of methods of litter application on volatile ammonia losses and movement of organic and inorganic constituents by surface and percolating water.

2.1233, ABSORPTION OF CHROMIUM BY CLAYS
T.F. CRAFT, Georgia Inst. of Technology, Engineering Experiment Station, *Atlanta, Georgia* 30332

The effectiveness of various clays and clay materials in the removal of chromium from dilute solution is to be evaluated. Chromium can be removed effectively from concentrated solutions such as certain industrial wastes, but the methods used are not satisfactory for treatment of dilute solutions. Specialized treatment methods are not usually available at municipal water treatment plants. Clay is stocked by many plants or is readily available and could be utilized in emergency situations if it reduces significantly the concentration of dissolved chromium.

Clays will be exposed to dilute chromium solutions and the equilibria and kinetics of sorption will be studied. Analysis of both the liquid and solid phases of the systems will be neutron activation.

SUPPORTED BY Georgia Institute of Technology

2.1234, WASTE TREATMENT AND ANALYSIS FOR THE CITY OF MACON, GEORGIA
R.S. INGOLS, Georgia Inst. of Technology, Engineering Experiment Station, *Atlanta, Georgia* 30332

The City of Macon has a major outfall sewer discharging into the Ocmulgee River without treatment. Directly adjacent to the outfall are two major industries also discharging untreated process waste water. While the city's waste water can be treated readily the chemical character and strength of the waste water from the Georgia Kraft Company and Armstrong Incorporated are not readily treated separately. Laboratory scale experiments have indicated that the three waste waters can be successfully treated after mixing.

A pilot plant has been developed for studying the size of a treatment plant required and for choosing the best technique of disposing of the byproduct sludges. The activated sludge process is being used in the pilot plant operation. The need for added mineral nutrients will be studied as well as possible sensor use for possible computer control.

Part of the study will involve information necessary to develop an equitable base for charging the industries for the cost of treating their waste water.

SUPPORTED BY Macon City Government - Georgia

2.1235, INTERACTION OF WATER WITH ORGANIC SPECIES
C.L. LIOTTA, Georgia Inst. of Technology, Water Resources Center, *Atlanta, Georgia* 30332

The objectives of this research are to determine the enthalpies (delta H), entropies (delta S), volumes (delta V) heat capacities (delta Cp) of ionization and dissolution in water of a series of representative organic acids and bases (phenols, carboxylic acids, thiols, amines and pyridines). These thermodynamic data have been shown to be useful in the ellucidation of the structure of water and the understanding of the nature of the interaction of water with charged and uncharged organic species. The free energies of ionization and dissolution will be determined from pKa, solubility and vapor pressure measurements. The corresponding enthalpy and heat capacity changes will be derived from high precision solution calorimetry data. Entropy changes may be calculated from the Gibbs relationship. The volume changes on ionization and dissolution will be calculated from density data derived from a high precision magnetic flow densitometer. The thermodynamic data derived from the above measurements will provide a basis for engineering calculations for the development of future designs for waste treatment projects and water contamination control.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1236, THE FINITE ELEMENT METHOD IN FLUID MECHANICS
P.G. MAYER, Georgia Inst. of Technology, School of Civil Engineering, *Atlanta, Georgia* 30332

The finite element method is a powerful analytical tool in solving engineering problems. The present study is undertaken to explore the applicability of this method to hydraulic engineering.

Successful solutions have to be found in steady saturated subsurface flows. The application is to be extended to time-dependent problems. Its immediate usefulness may be in problems involving heat dissipation and the disposal of biologically or chemically degradable liquid wastes.

SUPPORTED BY Georgia Institute of Technology

2.1237, MEASUREMENT OF ACTIVE BIOMASS CONCENTRATIONS IN BIOLOGICAL WASTE TREATMENT PROCESSES
F.G. POHLAND, Georgia Inst. of Technology, School of Civil Engineering, *Atlanta, Georgia* 30332

The purpose of the proposed research is to define the applicability and limitations of the dehydrogenase test for measurement of the active biomass used during treatment of domestic and industrial wastewaters. The specific objectives of the project are: (a) to study the effects of nutritional deficiencies and varying the organic content of wastewaters on the dehydrogenase activities of biological sludges, (b) to study the relationship between the active biomass concentrations and dehydrogenase activities of biological sludges undergoing endogenous metabolism; and (c) to develop a laboratory procedure for correlating dehydrogenase activities with the active biomass concentrations of biological sludges obtained from prototype domestic and industrial treatment processes.

The research effort will be divided into four parts including batch and continuous flow studies with pure and heterogeneous cultures. Pure culture studies will be conducted with E. coli and P. aeruginosa whereas the mixed cultures used will be derived from conventional wastewater treatment processes. Special complete mix batch and continuous flow reactors will be employed with selected substrates. Correlation of dehydrogenase activity with active biomass concentration will be obtained by standard plate and Coulter Counter enumeration, solids determinations, and enzymatic assays for dehydrogenase and substrate concentrations. The research results should provide a more reliable procedure for measurement of active biomass in both the process culture and recycle streams of conventional wastewater treatment processes including limits of its applicability to process design and control under the influence of changing environmental stresses.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.1238, TREATMENT OF SELECTED INTERNAL KRAFT MILL WASTES IN COOLING TOWERS
R.B. ESTRIDGE, Georgia Kraft Company, *Rome, Georgia* 30161

The objectives of this project are to determine the technical and economic feasibility of using cooling towers to reduce BOD

and heat content of kraft mill wastes and to reduce water usage in kraft mills. Studies will be carried out on both a pilot scale cooling tower and a large scale cooling tower.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1239, POLLUTION AND REUSE OF WASTEWATER EFFLUENTS AND STORMWATER IN HAWAII

L.S. LAU, Univ. of Hawaii, Water Resources Research Ctr., *Honolulu, Hawaii* 96822

The proposed research will determine the physical, chemical, and microbiological characteristics of the wastewater effluents and stormwater runoff from representative areas on Oahu, Hawaii. Further, it is proposed to relate the characterization to the Hawaii Water Quality Standards, to determine treatment required, and to evaluate suitability for reuse such as irrigation and artifical recharge.

The stormwater study will be conducted in representative land-use areas, such as, prime agricultural, residential, and industrial. Both the yields of stormwater from storm drains and streams will be studied. The wastewater effluents will be sampled from existing treatment facilities, including primary treatment plants and secondary treatment plants using activated sludge, trickling filter, and extended aeration processes. The quality constituents under study will reflect the concern in the Hawaii Water Quality Standards. All sampling will be conducted over a 12-month period. Wastewater effluents will be studied in f.y. 1970 followed by stormwater study for industrial and residential areas in F.Y. 1971, and by stormwater study for agricultural areas in F.Y. 1972.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1240, HYDROLOGY OF SUBSURFACE WASTE DISPOSAL - NATIONAL REACTOR TESTING STATION, IDAHO

J.T. BARRACLOUGH, U.S. Dept. of the Interior, Geological Survey, *Idaho Falls, Idaho* 83401

Objectives of this project are to acquire information on the geohydrologic and geochemical environment of the National Reactor Testing Station, requiring a study of the composition and structure of the earth materials underlying the plain, the inventory and continued evaluation of the water resources, the dynamics of the hydrologic cycle, and relevant geochemical processes. This information will help to determine within the environment the concentration of any increment of aqueous waste disposed and to define it qualitatively in time and place.

Attempts will be made to determine the direction and rates of vertical and lateral ground water movement within the basalt aquifer system, movement and dispersion of radioactive wastes, the volume of regional ground water movement and storage, and to apply the techniques of radioactive dating of the quaternary basalt and Tertiary rocks exposed in the area to the solution of structural problem significant in the geohydrology of the Station.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.1241, THE FEASIBILITY OF REUSE OF CHLORINATED SEWAGE EFFLUENT FOR FERTILIZATION AND IRRIGATION IN IDAHO

R.E. WILLIAMS, Univ. of Idaho, Graduate School, *Moscow, Idaho* 83843

The objective of this study is the evaluation of the feasibility of statewide reuse of sewage effluent. The steps to be taken consist of: 1. Location of communities in Idaho producing sufficient volumes of effluent to merit construction. 2. Determination of average annual volume of effluent of reuse facilities produced by each community -- minimum usable volume will have to be determined during the course of the study. 3. Determination of type of treatment employed by each community. 4. Determination of type and thickness of soils and geologic formations in each community. 5. Determination of distance from each community to irrigated crop land or to a forested area which might receive effluent. 6. Determination of types of crop grown in each irrigated area. 7. Determination of type of irrigation system employed in each area. 8. Estimation of cost of introducing sewage effluent from each locality into the existing irrigation system. 9. Estimation of cost of chlorination of effluent. 10. An analysis of existing devices in each locality which may be used for the monitoring of the quality of waters moving downward toward the ground-water table. 11. Determination of distance from ground surface to ground-water table in each locality. 12. When possible an interpretation of the direction of movement of ground water at each locality. 13. Determination of annual volume of phosphate and nitrate currently applied to the irrigated land in each locality investigated -- the volume of effluent required to duplicate this application rate can subsequently be estimated.

Once these data have been collected and analyzed, it will be possible to define those areas in Idaho wherein the addition of sewage effluent to streams can be eliminated and safely and beneficially applied as fertilizer and irrigation waters to crop or forest lands.

2.1242, STUDY OF METHODS FOR REDUCING WATER POLLUTION FROM STORM SEWER AND COMBINATION DISCHARGES THROUGH DEFINED PUBLIC WORKS PRACTICES

R.H. SULLIVAN, Amer. Public Works Assn., *Chicago, Illinois* 60637

Pollution of storm water in urban areas is a result of contact with features which can be controlled to some degree by man. This study is designed to identify the relative importance of features which may contribute to the pollution such as litter, air pollution, chemicals used for control of ice and snow, and pesticides. In addition operation and maintenance practices for combined sewer systems will be investigated to determine means of reducing pollution from overflow.

Public Works practices will be reviewed and procedures outlined which would affect a reduction in storm water pollution.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1243, ARMOUR INDUSTRIAL CHEMICAL SECONDARY WASTEWATER TREATMENT

E.F. HARP, Armour & Company, *Chicago, Illinois* 60611

The waste water from Armour Industrial Chemical Co.'s plant consists of a mixture of fatty acids and nitrogen derivatives of fatty acids such as nitriles; primary, secondary and tertiary amines; diamines; quaternary salts; and ethoxylated compounds. The pollutants are in part dissolved and emulsified and cannot be completely removed by a primary clarifier which is currently in use. Laboratory tests by Hydroscience, Inc. have indicated that aerobic biological treatment of the effluent from the clarifier is effective in reducing the COD, BOD, and hexane solubles of the waste stream. A pilot operation is currently being conducted to demonstrate the effectiveness of biological treatment on a larger scale and over a prolonged period of time to determine the effect of changes in flow rate and composition. The effectiveness of the secondary treatment is determined by measuring hexane solubles and the goal is to get down to 100 ppm or less in order to satisfy the Metropolitan Sanitary District of Chicago which has jurisdiction over the effluent leaving the plant.

If the pilot operation is successful, then a full scale aerated biological treatment system will be built to handle the entire effluent flow from the primary clarifier and a one year demonstration will be conducted under this grant.

2.1244, WHITE WATER CLARIFICATION AND REUSE

E.G. FOCHTMAN, I I T Research Institute, *Chicago, Illinois* 60616

Work is directed toward the determination of preferred methods of using retention aids in the paperboard process. Flocculation of cellulose fibers is being monitored by electrokinetic measurements. The many retention aids which are currently commercially available are being evaluated to determine their cost-effectiveness and the conditions for optimum use.

SUPPORTED BY Boxboard Research & Development Assn.

2.1245, PHOTOLYSIS MECHANISMS FOR POLLUTION ABATEMENT
L.C. KINNEY, IIT Research Institute, *Chicago, Illinois* 60616

To determine the feasibility of oxidizing the soluble organic materials in wastewater by contacting the water with photoreactive materials. The photoreactive materials for this application would be those capable of producing active oxidizing species upon exposure to sunlight or the light from inexpensive artificial sources.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1246, AMMONIA STRIPPING MATHEMATICAL MODEL FOR WASTE WATER TREATMENT
R.H. SNOW, IIT Research Institute, *Chicago, Illinois* 60616

To develop a mathematical model of air stripping of ammonia from waster water. Variables to be considered are: pH, post-precipitation, operating temperature ranges, distribution of capital and operating costs. The model will be written in a FORTRAN language applicable to an IBM 360/65 computer.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

2.1247, USE OF COAGULATION IN THE FLOTATION OF WASTEWATER
C.F. GURNHAM, Illinois Inst. of Technology, School of Engineering, *Chicago, Illinois* 60616

'Gross flotation' is the removal from a water medium of all species of particulate matter, including oily droplets, by attachment to the particles of freshly nucleated gas bubbles, followed by gravity separation and skimming. This process is currently in use for the treatment of industrial and municipal wastewaters, and serves to remove suspended matter including much that is not removable by the more conventional operations of primary treatment. Along with the suspended matter removal, the biochemical oxygen demand and other parameters of stream pollution are simultaneously reduced.

The process of gross flotation would be more widely used, to the benefit of the nation's waterways, if some of the present operating difficulties were better understood and could be removed, and if the operating efficiency of the process could be improved. The use of chemical coagulation in conjunction with gross flotation is an obvious means for improvement. Some waste treatment facilities have successfully employed this technique; other attempts have failed completely. Recycle ratio is undoubtedly a significant variable; zero recycle gives the maximum yield of bubbles and the opportunity for nucleation on the dispersed particles, but damages or destroys the coagulant floc by the necessity of passing it through a pump and other constrictions. Increasing recycle ratios can eliminate the latter problem, and may still produce an adequate bubble yield. Nucleation, however, is an essential and little understood aspect. The hypothesis of time lag in nucleation and of a possible very significant distinction between nucleation in homogeneous and heterogeneous fluid media are to be investigated in the project.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1248, FEASIBILITY OF SUBSURFACE LIQUID-WASTE DISPOSAL IN PENNSYLVANIA
N. RUDD, Geoengineering Labs. Inc., *Mount Vernon, Illinois* 62864

To provide: (1) a comprehensive review of the principles involved in subsurface liquid-waste disposal and possible effects upon the rock/fluid system; (2) a review of available techniques for site selection, control, and monitoring; and (3) a study of the regional geology of Pennsylvania drawing attention to factors favoring or inhibiting the development of disposal facilities. The study is intended primarily to provide a background for non-geological personnel concerned with liquid-waste-disposal operations.

The study was based on extensive review of pertinent literature, investigation of governmental and industrial records, and conventional sources of regional geological information.

SUPPORTED BY Pennsylvania State Government

2.1249, LOWER COST PROCESS FOR REFINING SOYBEAN OIL WITH REDUCTION OF WATER POLLUTION
R.A. EISENHAUER, U.S. Dept. of Agriculture, Northern Utilization Res. Div., *Peoria, Illinois* 61604 (N4-2-120)

OBJECTIVE: Develop a lower cost process for refining soybean oil and reduce stream pollution by minimizing refinery waste.

APPROACH: Investigate various types of ion-exchange resins as to particle size, type of functional group ion-exchange capacity, and ease and cost of regeneration, and relate these factors to effectiveness of sodium ion removal from a refined soybean oil. Determine variables such as feed material, regenerants, water rinses, wastes, operating temperature, and methods of analysis. Study both batch and continuous countercurrent processes. Determine if heat bleaching, which occurs during deodorization, can be made adequate to produce high-quality salad oil. Scale up the most promising process to pilot-plant size and make cost analyses.

PROGRESS: Water-recycle washing of alkali-refined, unwashed soybean oil was further investigated in a vertical rotating disc, countercurrent contactor, and in a cocurrent mixer and centrifuge with about equally satisfactory alkali reduction in both types of equipment. The cocurrent mixer-centrifuge is the type of system employed in commercial refineries for washing alkali-refined vegetable oils. Therefore, with only the addition of ion-exchange equipment and accessories, washing equipment now in use can be converted to water- recycle operation with the expectation of satisfactory results in terms of adequate sodium removal and complete recycle and reuse of wash water.

SUPPORTED BY U.S. Dept. of Agriculture

2.1250, BIOLOGICAL ASPECTS OF TERTIARY PONDS
R.L. EVANS, State Water Survey, *Urbana, Illinois* 61801

Tertiary ponds of relatively short detention periods (2-5 days) have successfully demonstrated their value in improving the effluent from secondary units of sewage treatment works. Field observations of a 23-acre pond complex, with depths varying from 10-16 feet receiving treated sewage at an average flow of 2.5 mgd revealed the major biological organisms, other than bacteria, to be protozoa. An investigation has been undertaken to monitor the phytoplankton population in the ponds and associated environmental conditions for an 18-month period.

SUPPORTED BY Illinois State Government - Springfield

2.1251, DIATOM REMOVAL BY FLOCCULATION
R.L. EVANS, State Water Survey, *Urbana, Illinois* 61801

Plankton examinations suggest the principal forms of algae in Peoria Lake (on Illinois River) are diatoms. Studies indicate that some of the abudant genera are those associated with sand filter clogging. An existing water treatment plant pumping 5 mgd from Peoria Lake provided a means for determining the removal efficiency of plankton in a clarifier preceded by a flocculation unit. A bench study is under way for the purpose of gaining some insight into the relationship of alum dosages and plankton removal as well as the effects of other additives such as potassium permanganate.

SUPPORTED BY Illinois State Government - Springfield

2.1252, NUTRIENT REMOVAL IN A WATER TREATMENT PLANT
R.L. EVANS, State Water Survey, *Urbana, Illinois* 61801

The Illinois River with a total phosphorus concentration ranging from 0.5 - 3.0 mg/l (as P) serves as a source of water for the city of Peoria. Treatment units consisting principally of a flocculator, clarifiers, and sand filters produce potable water. The

uses of chemical coagulants, filtration, and biological stripping have been demonstrated as possible avenues for phosphorus removal. This study involves the collection and analyses of water samples for the purpose of determining the extent of phosphorous and ammonia-N removal as well as changes in COD, BOD, total residue, and others and the role each treatment unit contributes to such removal or changes in concentration.

SUPPORTED BY Illinois State Government - Springfield

2.1253, WATER TREATMENT PLANT WASTES
R.L. EVANS, State Water Survey, *Urbana, Illinois* 61801

A study is under way to determine the effect, if any, that wastes generated by water treatment plants may have on potential or existing water supply sources, as well as other legitimate users of water. An effort has been made on a statewide basis to determine 1) existing methods of water treatment wastes disposal; 2) types and quantities of waste generated per unit quantity of water treated; and 3) chemical, physical, and biological characteristics of the wastes.

That phase of the project involving classification units and water softening is complete. Current efforts are devoted to investigating municipal ion-exchange units involving principally brine wastes.

SUPPORTED BY Illinois State Government - Springfield

2.1254, PILOT SCALE INVESTIGATIONS OF WELL RECHARGE USING CORED SAMPLES
H.F. SMITH, State Water Survey, *Urbana, Illinois* 61801

Purpose of this study is to determine the feasibility of recharging treated sewage effluent into the Cambrian-Ordovician (deep sandstone) aquifer in northeastern Illinois.

The physical, chemical, and biological factors affecting rates at which the effluent can be injected into the aquifer are being investigated. The effectiveness of the filtering action of the aquifer is being studied. Methods of further treatment of secondary or tertiary treated sewage effluent are being investigated so that effluent can be successfully used to recharge the aquifer system. Some success was had in maintaining constant recharge rates at constant heads through sandstone cores.

One objective of further study will be to maintain constant recharge rates for longer periods of time.

SUPPORTED BY Illinois State Government - Springfield

2.1255, THICKENING AND DEWATERING OF WATER TREATMENT SLUDGE
R.I. DICK, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

Laboratory and full scale plant investigations are being conducted to develop operational parameters for a gravity thickener to yield optimum volume reduction and solids concentration. Further dewatering investigations have involved the use of various polyelectrolytes to improve the filterability of the softening-clarification sludge by an existing vacuum coilfilter.

SUPPORTED BY Decatur City Government - Illinois

2.1256, MECHANISMS OF SLUDGE THICKENING
R.I. DICK, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

It is proposed to continue previous work which has shown present criteria for evaluating the solids loading capabilities of settling tanks to be inadequate when applied to activated sludge because of their failure to consider the rheological properties of the material. Attempts will be made to define the fundamental mechanisms which control the behavior of the sludge. The techniques for examining the thickening properties of activated sludge will be extended to other suspensions which are troublesome in water and wastewater treatment because of their failure to consolidate into compact masses. Results of laboratory batch settling tests will be compared to the performance of continuous processes in the laboratory and the field. Knowledge of the basic properties of the suspensions will be employed to evaluate possible chemical physical or biological processes or alterations of conventional processes which might improve the effectiveness of sludge thickening. Rational bases of design of the thickening portion of settling basins, as suggested by results of the fundamental studies, will be proposed.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1257, UPTAKE AND RELEASE OF SOLUBLE ORTHOPHOSPHATE BY ACTIVATED SLUDGE
R.S. ENGELBRECHT, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

A laboratory study of the effectiveness of the activated sludge process to remove phosphorus from liquid wastes has been carried out. The overall objective of the investigation was to examine the parameters that are involved in optimizing the uptake of soluble orthophosphate, and minimizing the release of soluble orthophosphate by activated sludge mixed liquor suspended solids. The variables considered were temperature, pH, food to microorganisms (F/M) ratio, contact time, aeration rate, concentrations of orthophosphate, dissolved oxygen, and degree of mixing.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1258, NEW MICROBIAL INDICATOR OF WASTE-WATER CHLORINATION EFFICIENCY
R.S. ENGELBRECHT, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

The primary objective of this research is to find a suitable and reliable indicator of the destruction of enteric pathogens by chlorine and to develop a simple and rapid means of determining the numbers of such an indicator in chlorinated wastewater effluents. Screening by chlorinating effluents from several types of present-day wastewater treatment facilities will be employed initially to provide isolates which are chlorine resistant. Media and growth conditions will be varied so as not to eliminate from consideration organisms of high chlorine resistance which may fail to proliferate under commonly used growth conditions. The chlorine resistance of successful isolates will then be studied in detail under controlled laboratory conditions both in pure and mixed cultures and under varying concentration and different chemical species of chlorine. When acceptable chlorine resistance of several organisms has been established, these will be compared to the resistance of selected enteric pathogens as well as coliform bacteria, the presently accepted indicator organism. At the same time rapid and simple means of quantitative detection of the proposed indicator will be developed.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1259, CHLORINATION OF WASTE WATER EFFLUENTS
R.S. ENGELBRECHT, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

The objective of this study was to investigate the effect of a chlorinated waste effluent on the bacteria population of a small, receiving stream. The effluent from the activated sludge treatment plant at Paxton, Illinois, discharges into a small stream which was sampled above and below the outfall. Effluent and the steam samples were analyzed for total coliform, fecal coliform, and enterococcus bacteria in the absence of and during chlorination of the waste effluent.

SUPPORTED BY University of Iilinois

2.1260, BIOMASS PRODUCTION FOR THE IMPROVEMENT OF THE QUALITY OF FOOD PROCESSING PLANT EFFLUENTS
Z.J. ORDAL, Univ. of Illinois, School of Agriculture, *Urbana, Illinois* 61801

The main objective of the proposed research is to develop a system for the improvement of the quality of food processing plant effluents. The thesis is that if the carbon to nitrogen ratio of the raw wastewater is properly adjusted, conditions can be

established which will produce a maximum biomass. Removal of the biomass will yield an effluent low in organic matter and low in nitrogen and the associated eutrophic elements. A composite wastewater from a dairy processing plant will be evaluated.

The laboratory investigation will include the following: 1. Develop an inocula by batch culture studies. 2. Evaluate a continuous culture system based on: a. The nutritional requirements for maximum biomass production. b. Manometric techniques for the determination of operational parameters. c. Modification of the system to determine practical operating parameters. 3. Removal of the biomass and analysis of the supernatant fluid (effluent) for BOD, COD, pH, N, P, and K.

Further studies will involve the evaluation of the biomass for its value as a feed supplement.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1261, RECLAMATION OF ENERGY FROM ORGANIC REFUSE

J.T. PFEFFER, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

The study is currently investigating the energy yield from anaerobic fermentation of organic refuse from systems operating at 35 degrees C. The systems are receiving shredded domestic refuse at loadings of 0.1 and 0.2 lbs volatile solids per cubic feet per day. The retention time is controlled by varying the solids content of the slurry from 5 percent to 40 percent. Efficiency of conversion is measured by the quantity of gas generated and the degree of solids destruction. Also the stability and dewatering characteristics of the residue is being evaluated.

Conversion of the organic carbon to methane by anaerobic fermentation is widely used in the treatment of waste sludges from wastewater treatment plants. This conversion reclaims a significant portion of the energy of this waste material as well as reduces the quantity of the solids by converting them to the gaseous end product.

The technology of anaerobic fermentation has advanced greatly in the past decade. These systems can be loaded at high loading rates and achieve nearly complete conversion of the organic solids to gases if the retention time is sufficiently long. The water content of the feed slurry markedly affects the size of the reactors required to obtain the degree of conversion desired. Since organic solid wastes have a low water content in comparison to wastewater sludges that are currently used in these systems, it will be possible to obtain the desired conversion without the need for excessively large reactors.

2.1262, EFFECT OF CHLORINATION ON CILIATE PROTOZOA AND THEIR ROLE AS A BARRIER TO STREAM POLLUTION

E.B. SMALL, Univ of Illinois, Graduate School, *Urbana, Illinois* 61801

This investigation will study two significant relationships of the ciliate protozoa present in a heavily, biologically polluted portion of the Saline Ditch in Champaign County, Illinois. One relationship is the role played by the ciliates as a natural barrier to the biological pollutants of the Champaign-Urban sewage effluent. To be investigated here will be (1) the nature of the ciliate flocculating process and (2) the chemical and physical factors (e.g. dissolved oxygen and temperature) which may control the density of the protozoan population. The second relationship is the effect, either direct or indirect, that chlorine in various representative dilutions may have upon the protozoan populations. In the laboratory, field samples of controlled temperature circulating growth chambers where the ciliate population as well as temperature, dissolved oxygen and other factors will be monitored by electronic sensors and time lapse microcinematography. These results will be compared to the chlorine effects noted when this chemical sterilant is added to the effluent.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1263, COMPETITIVE ADSORPTION IN THE REMOVAL OF ORGANIC POLLUTANTS FROM AQUEOUS SOLUTION

V.L. SNOEYINK, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

This research involves a study of the competitive interactions of adsorbates in multi-solute systems on the extent of adsorption of these adsorbates. The adsorbent of interest is activated carbon. Bi-solute, batch systems will be used. Parameters of interest include molecular size and configuration, charge and type of molecule. The objective of this research is to develop a model which can be used to predict the competitive effects.

SUPPORTED BY University of Illinois

2.1264, DISINFECTION OF SEWAGE EFFLUENTS

F.W. SOLLO, Univ. of Illinois, State Water Survey Division, *Urbana, Illinois* 61802

A study is being made of the effectiveness of bromine as a disinfectant for treated sewage effluents under varied conditions of temperature, pH, and bromine concentration in parallel with a study with chlorine as the disinfectant. Disinfection is being measured in terms of coliform, fecal coliform, and total bacterial numbers.

In addition, two streams receiving treated effluents, one chlorinated and the other to be chlorinated in the near future, are being surveyed to determine the effect of chlorination on both bacterial counts and general stream chemistry.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1265, EAST CHICAGO TREATMENT LAGOON

C. LEAHU, East Chicago Sanitary District, *East Chicago, Indiana*

The project will evaluate the effectiveness of treating combined sewer overflows in a very deep detention basin having aerobic and anaerobic levels of treatment. The aerobic treatment is accomplished by large oxygen transfer units suspended on surface of basin waters.

The major features of this project are: 1. One 20-acre, 40-foot deep, 200 million-gallon capacity detention basin. 2. Nine 50-HP, oxygen transfer units. 3. 2500 lineal-feet of prestressed concrete pressure pipe, 84 inches in diameter. 4. Chlorination equipment necessary for treating effluent from detention basin. 5. Necessary water quality and quantity monitoring equipment. 6. Necessary evaluation required to meet demonstration program objectives.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1266, MICROBIAL INTERACTIONS IN WASTE TREATMENT SYSTEMS

D.J. KIRSCH, Purdue University, School of Engineering, *Lafayette, Indiana* 47907

The growth and metabolic activity of methane-producing bacteria grown in association with both selected pure and mixed cultures of predominant bacterial types isolated from anaerobic digesters are being evaluated. A simulated mixed culture digestion system is being used; it employs semi-permeable membranes to effect physical separation of the cultures under investigation.

2.1267, EFFECTS OF DOMESTIC POLLUTION ABATEMENT ON A EUTROPHIC LAKE

M.W. TENNEY, Univ. of Notre Dame, School of Engineering, *Notre Dame, Indiana* 46556

The primary objective of this project is to demonstrate changes in a eutrophic lake following complete removal of all domestic pollution. Project results will then be used as a basis for suggesting possible external manipulation of the lake that may accelerate or promote beneficial natural changes. Initial studies will

include physical, chemical and biological studies of the existing source of pollution and lake conditions. After removal of the source of pollution the same studies will continue on the lake basin.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1268, REMOVAL OF ORGANIC AND EUTROPHYING POLLUTANTS BY COMBINED CHEMICAL AND BIOLOGICAL TREATMENT

M.W. TENNEY, Univ. of Notre Dame, School of Engineering, *Notre Dame, Indiana* 46556

The object of this project is to demonstrate by pilot plant techniques the operational feasibility and economic aspects of a combined biological and chemical treatment scheme for the removal of organic, nitrogenous and phosphatic pollutants from industrial and municipal wastewater. The project was started in fiscal year 1968 and it is anticipated that it will be completed in fiscal year 1970.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1269, AMES DESIGN PARAMETERS

E.R. BAUMANN, Iowa State University, School of Engineering, *Ames, Iowa* 50010

Over the years the City of Ames and the Sanitary Engineering Section of the Engineering Research Institute have cooperated in conducting a number of full-scale studies at the Ames water treatment and water pollution control plants. Studies of the sand filters and treatment processes at the water treatment plant built in 1928 permitted the expansion of plant capcity from 2.6 to 8.0 mgd with a savings of more than $1,000,000 in construction costs.

The City of Ames is scheduled to put into operation an expanded water pollution control facility by 1972. This study is evaluating the design parameters which should be used for the expansion of the pollution control plant. The location of the City of Ames on a relatively small river, which is periodically dry poses design considerations similar to those encountered frequently in Iowa. The evaluation of the design parameters for a pollution control plant at Ames will provide a basis for evaluation of many similar plants in the state.

SUPPORTED BY Ames City Government - Iowa

2.1270, DEVELOPMENT OF PULSATING ADSORPTION FILTER FOR TERTIARY TREATMENT OF WASTE WATERS

R.L. JOHNSON, Iowa State University, School of Engineering, *Ames, Iowa* 50010

In the near future, many of the effluents from conventional sewage treatment facilities will need further tertiary treatment to reduce the organic pollution load entering our waterways. The proposed research will determine the design and operating parameters for a new type of tertiary treatment process, first through laboratory scale investigations using synthetic sewage and second by pilot plant operation of the process on actual secondary sewage plant effluent.

The new process will utilize the adsorption phenomenon of the organic materials onto sand, coal and other media, with the adsorption providing a concentration effect. This concentration of the organic material in the presence of oxygen and biological life allows further bio-degradation of the organic material. The air supply to the process provides the required oxygen for the biological life as well as the pulsating effect needed to prevent clogging of the media beds.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1271, TREATMENT OF AQUEOUS AGRICULTURAL WASTES FOR CLEAN WATER AND FOR MICROBIAL PROTEIN PRODUCTION

G.T. TSAO, Iowa State University, School of Engineering, *Ames, Iowa* 50010

The present proposal concerns a study of a biological engineering process for treating extremely high BOD (biological oxygen demand), heavily contaminated, aqueous agricultural wastes to produce microbial cells, in an unusual culturing vessel known as the Waldhof fermentor. Because of their content of surface active agents, agricultural wastes usually foam excessively when bubbled with air for oxygen supply. Ordinary sparger-agitator type of culturing vessels cannot be used for this purpose due to the high antifoaming demand. The Waldhof fermentor actually makes a virtue of extreme foaming properties and accomplishes high degree of aeration by making use of foam which has a large air- liquid contacting interface. The foam is continuously recycled in the system.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1272, LIMNOLOGICAL INVENTORY OF IOWA LAKES AND STREAMS

UNKNOWN, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01564)

Progress: Major emphasis was placed on studies of tertiary treatment ponds for the improvement of water quality in the effluent of municipal waste treatment plants. In a series of four ponds at Ames, Iowa it was found that during the warm months of the year, such ponds were effective in reducing concentrations of ammonia, inorganic phosphorus and nitrates. In addition by stocking channel catfish in the four ponds, it was found that the ability of the effluent to support fish populations was improved by passage through the ponds and that a profitable harvest of fish for restocking could be obtained from the last two ponds in the series. A graduate thesis was completed on the limnology of DeSoto Bend Lake. It was found that the prevalent lake bottom material was sand. Lake water levels appeared to be dependent on the ground water level and the Missouri River water levels. Intermittent thermal stratification occurred in the summer. The bottom fauna consisted mainly of chironomids and oligochaetes, and that the higher aquatic vegetation had increased over the past nine years but comprised only 1% of the total lake surface area.

SUPPORTED BY Iowa State Government - Des Moines

2.1273, CRITERIA FOR WASTE-DISPOSAL SITES IN THE KANSAS RIVER VALLEY

P.L. HILPMAN, Univ. of Kansas, State Geological Survey, *Lawrence, Kansas* 66044

Will honor any reasonable request for further information. To determine geologic criteria essential to establishment of standards for the evaluation of applications for waste-disposal sites in the Kansas River Valley.

To prepare a series of factor maps of water-table depth, water- table fluctuation, locations of deep Pleistocene channels in alluvium, areas of high scour potential, and quality of water. Sets of observation wells will be established locally to allow qualitative and quantitative analysis of ground water. Natural and man-made changes in the regimen of some parts of the Kansas River will be monitored to try to predict water-level fluctuations and erosion potentials. A sub- project will include a feasibility study of nearby upland sites as alternatives to waste disposal in valley alluvium.

SUPPORTED BY Kansas State Government - Topeka

2.1274, CATTLE FEEDLOT WASTE WATER TREATMENT

R.E. MCKINNEY, Univ. of Kansas, School of Engineering, *Lawrence, Kansas* 66044

This project is concerned with a combined anaerobic-aerobic treatment of cattle manure washed from a feedlot by rain. The liquid runoff is collected in an anaerobic lagoon where it is partially decomposed. The liquid displaced from the anaerobic unit is treated aerobically to remove the remaining BOD. The treated material must be discharged onto fields.

This project has supported two students a year.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1275, USE OF LIME-SODA ASH SLUDGE FOR THE TREATMENT OF MUNICIPAL WASTEWATER
W.J. OBRIEN, Univ. of Kansas, School of Engineering, *Lawrence, Kansas* 66044

The objectives of this research are to analyze the excess sludge produced by the lime-soda ash water softening process used in the municipal water treatment plant at Lawrence, Kansas, and to determine the effectiveness of this material as a precipitant for wastewater.

The water softening sludge will be added to the primary sedimentation basin in the municipal wastewater treatment plant to determine the level of phosphate and suspended solids removal that can be obtained at a pH of 9.5 in the sedimentation basin. Final disposal methods for the mixture of biodegradable organic matter and chemical sludge produced at the wastewater treatment plant will also be investigated.

Both laboratory and plant scale tests will be conducted. An economic evaluation of the process will also be prepared.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1276, EXPERIMENTAL OPTIMIZATION OF STEP AERATION WASTE TREATMENT SYSTEMS
L.E. ERICKSON, Kansas State University, School of Engineering, *Manhattan, Kansas* 66502

This proposal is for an experimental investigation of the optimum hydraulic regime for the step aeration biological waste treatment process. Experimental research will be conducted to verify experimentally the available theoretical results on the optimum hydraulic regime for biological waste treatment systems. The important parameters in the mathematical models will be experimentally measured and the correspondence of the models with experimental observations will be examined. Experimental search procedures will be used to experimentally determine the optimum hydraulic regime. The results will be compared with the optimum predicted by the mathematical models.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1277, OPTIMAL DESIGN OF WASTE TREATMENT SYSTEMS
L.T. FAN, Kansas State University, School of Engineering, *Manhattan, Kansas* 66502

The purpose of this investigation is to extend research related to an ongoing research program OPTIMAL DESIGN OF WASTE TREATMENT SYSTEMS which has been supported by FWPCA since June of 1967 (FWPCA Grant No. 01141-01 and Grant No. 1WP-01141-02). The primary objective of the ongoing research program has been and still is to develop optimal designs for a variety of waste treatment systems and to establish methods for designing optimal systems. More specifically, the program involves analysis, optimization, and process design studies of both conventional and modified activated sludge processes, anaerobic digestion processes and entire treatment systems.

The proposed investigation can be roughly classified into the following several areas, namely, Simulation and Optimization of Subsystems and Components of the Wastewater Treatment System, Experimental Verification of the Results of Optimal Design Studies, Experimental Optimization of the Activated Sludge Waste Treatment System, and Simulation and Optimization of the Entire Wastewater Treatment System. Efforts will be made to account for the effects of mixing and the dynamics caused by flow rate and concentration transients in the feed stream in this analysis. Sensitivity analysis will be used to focus attention upon the most important design variables. It is anticipated that the newly proposed work will be started in June 1970 and be completed in two years.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1278, BIOLOGICAL TREATMENT OF BEEF ANIMAL WASTES TO REDUCE WATER POLLUTION
R.I. LIPPER, Kansas State University, School of Engineering, *Manhattan, Kansas* 66502

Water pollution resulting from cattle feeding operations could be reduced greatly if cattle were reared in confinement on concrete so that wastes could be readily collected for biological treatment. Poultry and swine producers have already demonstrated that confinement rearing is practical on a large scale. Confinement systems for beef production are being investigated. This research proposes to evaluate two systems for the biological treatment of beef cattle wastes. A recirculating oxidation ditch will be operated under a slotted floor for pens holding twenty beef animals in an open front shed. Another shed with capacity for twenty animals will have a solid concrete floor. Manure from the second shed will be pushed into a waste collection hopper at weekly intervals. Waste from the hopper will be fed into a mixed, anaerobic treatment system. Total and volatile solids, BOD and COD will be determined for material fed to each system. The efficiencies and operating characteristics will be determined for each system. The adaptability of the system to cattle management schemes will be evaluated.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1279, PILOT PLANT DEMONSTRATION OF A LIME-BIOLOGICAL TREATMENT PHOSPHORUS REMOVAL SYSTEM
L.A. SCHMID, Kansas State University, School of Engineering, *Manhattan, Kansas* 66502

The economical removal of phosphates from domestic wastewaters is a problem facing many municipalities as water quality regulations in many areas of the country now specify 80 percent or better removal of phosphate.

Laboratory research has shown that a process of lime treatment followed by biological treatment may be quite economical. Raw wastewater is first coagulated with lime and settled. The supernatant, with reduced BOD and phosphate concentration, is then subjected to a high rate, complete mix activated sludge process. Microbial metabolism of the remaining organic load results in near complete conversion of the remaining phosphate into settleable cell mass.

A pilot plant of approximately 20,000 gallons per day is to be constructed to demonstrate the process and to develop design criteria, establish operational procedures, and to determine further the economics and limitations of the system.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1280, THE MECHANICS OF SEDIMENT REMOVAL FROM ALLUVIAL STREAMS
B.J. BARFIELD, Univ. of Kentucky, Agricultural Experiment Sta., *Lexington, Kentucky* 40506 (KY00119)

OBJECTIVE: Develop a mathematical model relating sediment concentration to stream flow parameters and use the model to design sediment removal structures.

APPROACH: Existing theories of turbulent diffusion will be utilized in developing a model of sediment movement as related to stream flow parameters. This model will be used in the design of sediment removal structures.

PROGRESS: Research during the year 1969 has been limited to completion of research apparatus for studying sediment movement in streams. This apparatus includes a 40 foot hydraulic research flume with an adjacent sump for storing water, a deionizer for providing high quality water, a calibrating tank for calibrating velocity probes. The facility is essentially complete and calibration is presently being accomplished.

SUPPORTED BY U.S. Dept. of Agriculture

2.1281, A FEASIBILITY STUDY OF ULTRAFILTRATION AND ELECTROPHORETIC DIALYSIS FOR RECOVERY OF VIRUSES IN WASTE AND OTHER WATERS
B.H. SWEET, Gulf South Research Institute, *Baton Rouge, Louisiana*

The objectives of this grant are to evaluate and determine the feasibility of utilizing the newer ultrafiltration techniques (reverse osmosis) with selective membranes alone or in combination with electrofiltration dialysis in concentrating and detecting viruses in waste and other waters.

Towards that end, a quantitative model system will be established using polio virus diluted in water or an appropriate diluent. This diluted virus will be subjected to concentration procedures utilizing various selective cellulosic asymmetric membranes, and employing hydrostatic or osmotic pressure gradients. Both static and continuous flow systems will be analyzed using modifications of the membrane pressure cells developed by Blatt.

The physical and biological parameters, effectiveness, and limitations of the system will be evaluated.

Studies will be initiated to evaluate the electrophoretic dialyzer- concentrator (Canalco) as a method of concentration and detection of polio virus which has been diluted in water. In addition, the procedure will be evaluated as a second step viral concentration procedure following the primary selective ultrafiltration step.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1282, PREVENTING LANDFILL LEACHATE CONTAMINATION OF WATER

E.J. WREN, Gulf South Research Institute, *Baton Rouge, Louisiana*

The objective of the proposed research is to develop materials or combinations of materials that will effectively serve as sealants for containment of leachates within sanitary landfills. This research will be conducted under conditions of high water tables, high temperatures, and some 60 inches of rainfall per year.

A survey of the availability of low cost industrial waste by-products will be made. Initial screening for permeability of promising materials will be done in our polymer chemistry laboratory in order to delete unsuitable products from further study. Materials which appear promising will then be tested in laboratory scale sanitary landfills. Sealant materials which pass this evaluation will then be tested in pilot field cells.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.1283, NONAQUEOUS TREATMENTS TO IMPROVE FABRIC PROPERTIES AND REDUCE WATER POLLUTION

T.A. CALAMARI, U.S. Dept. of Agriculture, Southern Utilization Res. Div., *New Orleans, Louisiana* 70119 (S2-1-374)

OBJECTIVE: Reduce stream pollution from cotton textile finishing plant effluents by developing nonaqueous scouring and mercerizing processes that also enhance the physical and smooth-drying properties of resin-treated fabrics.

APPROACH: Develop nonaqueous textile processes which will reduce stream pollution and also maximize smooth-drying appearance of resin- treated cotton fabrics. Use nonaqueous solvents in fabric preparation to minimize finishing plant effluent and also to prevent hydrogen bonding in fabrics. Investigate warp compaction as a method of relieving stresses and strains in fabrics. Employ steaming techniques and mercerizing solvents to remove undesirable creases. Apply polymers from aqueous and nonaqueous solvents to control deposition sites. Study combination of the above.

PROGRESS: The statistical experimental design for the project has been developed, six bales of cotton obtained from commercial sources, and one lot of experimental yarn processed. The 12/1 yarn has been given 18 different polymer treatments, and knitted into fabrics. The knit fabrics will be tested for dimensional stability and the permanence of the polymer film on the yarns. A conference was held with officials of the Department of Interior, Water Pollution Control Division, on water pollution problems due to textile processing. Technical literature and test methods were also obtained which will aid in guiding this research on minimizing stream pollution from textile sizing materials.

SUPPORTED BY U.S. Dept. of Agriculture

2.1284, WARP SIZES THAT AVOID STREAM POLLUTION AND IMPROVE DURABLE-PRESS FABRICS

I.T. LOFTON, U.S. Dept. of Agriculture, Southern Utilization Res. Div., *New Orleans, Louisiana* 70119 (S2-1-376)

OBJECTIVE: Develop warp-size formulations and slashing echniques that eliminate stream pollution and produce improved oven and knit durable-press fabrics.

APPROACH: Develop specific warp size formulations and slashing techniques for cotton yarns for producing woven and knit fabrics with improved durable-press properties using polymeric materials having durable and/or nondurable properties to produce both temporary and permanent coatings on cotton yarns. Select formulas showing the best results. Slash sufficient yardages of warp yarns and evaluate weaving and knitting efficiency. Chemically finish and evaluate durable-press fabrics produced from these yarns for specific end uses.

PROGRESS:

2.1285, EFFECT OF ANIMAL WASTES APPLIED TO SOILS ON SURFACE AND GROUND WATER SYSTEMS

F.E. HUTCHINSON, Univ. of Maine, School of Agriculture, *Orono, Maine* 04473

The vertical and lateral movement of nitrate and phosphate anions through soils will be studied in both the greenhouse and field following repeated applications of varying rates of poultry manure. The soils used will be selected to give a coarse-textured glacial outwash and a medium-textured glacial till.

In the greenhouse the soils will be placed in leaching columns where water samples can be removed at various depths to determine the vertical movement of the anions following manure application. The manure will be applied at varying rates and frequencies.

In the field, manure will be applied at varying rates to plots established on the two soils and the lateral as well as the vertical movement of nitrate and phosphate will be measured by sampling with tension lysimeters. At the glacial till site a small pond will be established down-slope from the plots to determine contamination of contiguous surface waters.

Data from controlled conditions (greenhouse) and field conditions will be correlated for practical application in the establishment of maximum loading rates for animals wastes applied to these types of soil. The proposed duration of this project is FY 1971 & 72.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1286, UNDERGROUND DISPOSAL OF LIQUID WASTES IN BRACKISH WATER FORMATIONS, MARYLAND

E.G. OTTON, U.S. Dept. of the Interior, Geological Survey, *Baltimore, Maryland* 21204

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of Maryland.

Purpose: To appraise some factors to be considered by governmental regulatory agencies in evaluating proposals for subsurface disposal of wastes.

Methods: The factors bearing on the feasibility of underground disposal in terms of geologic units which might be used, the methods used in underground disposal and the hydrologic conditions which govern the feasibility of underground disposal will be reviewed and evaluated. A preliminary estimate will be made of the chemical character of water in the geologic units which appear to offer promise as disposal reservoirs.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.1287, AGRICULTURAL PROCESSING PLANT WASTE WATER ACCOMMODATION BY FORAGES AND SOIL

J.H. AXLEY, Univ. of Maryland, School of Agriculture, *College Park, Maryland* 20742

Waste water from agricultural processing plants should be reactified before being dumped into the nearest stream. The processing of such water by classical procedure is a costly operation. In fact, such costs can at times be ruinous to the processor. One of the systems that operates with a minimum of cost and usually meets health requirements in the purification of water is the waste water sprinkler irrigation of soils. Here the soil and plant work as a team in the filtering off and removing from the waste water the undesirable material it carries. Fourteen forages will be studied under applications of effluent from a chicken processing plant.

The forages will be harvested usually 5 or more times a year and yields will be recorded. The plants will be analyzed for N, P, K and possibly other waste contaminants. The composition of the percolating water at 6, 12, and 36 inch depths in the soil will be determined under at least 3 legumes and 3 non-leguminous plants. Finally, as this is a study of a system of water purification the role of the plant and the soil as a means of removing and eliminating nitrogen from the soil solution found at the 3 foot depth will be studied with laboratory and field trials. Soil amelioration will also be investigated.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1288, POLLUTION LOADS IN PERCOLATE WATER FROM SURFACE SPREAD SWINE WASTES

H.L. BRODIE, Univ. of Maryland, School of Agriculture, *College Park, Maryland* 20742

One method of swine waste disposal is the spreading of the waste on the soil surface. Ground water contamination may result from unstable organic matter, excess nitrates, phosphates and other chemicals found in the waste. Utilizing a trench lysimeter, percolate water samples will be removed from vegetated plots to which solid and/or liquid swine wastes are applied. Waste application will be taken during the summer months. Percolate samples will be taken throughout the year. Percolate water and applied effluent will be analyzed for COD, N, P, Cl, Ca, E. Coli and Salmonella. The expected duration of the project is two years.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1289, EFFECTS OF ECONOMIC DEVELOPMENT UPON WATER RESOURCES

J.H. CUMBERLAND, Univ. of Maryland, Graduate School, *College Park, Maryland* 20740

This is a proposal to undertake research intended to provide improved data for water resource quality analysis and management. Recently published data on industrial wastes would be added as coefficients to tested economic models in order to permit measuring the specific effects upon water quality generated by each different industry as a function of the level of economic activity of that industry. This extension of economic models to include environmental pollution coefficients is intended to identify present and projected future water pollution abatement priorities and to identify opportunities for constructive use of waste through improved technology and practice.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1290, TREATMENT OF LIQUID WASTE FROM FOOD PROCESSING PLANTS

A. KRAMER, Univ. of Maryland, School of Agriculture, *College Park, Maryland* 20742

Incoming water, waste effluent, and liquid in the waste disposal systems of six commercial food processing plants will be analyzed for total solids, organic matter, certain cations and anions, pH, gases, and pesticide residues. On the basis of analytical findings, recommendations will be made on the most efficient means of water reuse before discharge, and studies will be conducted on possibilities of neutralizing, salting-out and otherwise eliminating deleterious materials from water in the plant for possible reuse, or from effluent to be collected as solids before entering the waste disposal system or direct release onto land or streams. Minimizing off-odors from waste accumulations will also be considered.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1291, DISPOSAL OF WASTE FROM SWINE FEEDING FLOORS TO MINIMIZE OR ELIMINATE STREAM POLLUTION

W.F. SCHWIESOW, Univ. of Maryland, School of Agriculture, *College Park, Maryland* 20742

A septic tank system will be constructed for disposal of wastes from a swine feeding floor to prevent effluent from such floors polluting streams. The effectiveness of such a system will be evaluated for its ability to reduce the biochemical oxygen demand (BOD) of such wastes and to dispose of the wastes by distribution through an underground tile disposal field. Data to be collected will include sludge buildup in the tanks and the gradients of distribution through the soil and the gradients of BOD reduction. The effectiveness of the septic tank and underground disposal system will be compared to that of a lagoon for which three years' operation history is available and which will be continued in service.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1292, DEVELOPMENT AND DEMONSTRATION OF METHODS FOR TREATMENT OF DAIRY FARM WASTEWATERS

D.S. KAPPE, H.L. Mills Brookl. Dairy Farm, *Hagerstown, Maryland* 21740

The object of this project is to develop and demonstrate a wastewater treatment system for satisfactorily treating animal wastes and runoff from dairy cattle holding areas, beef cattle feedlots, and similar places that have a reasonable first cost, low operating expense, and minimal maintenance requirements. Under the project program, an experimental treatment facility will be designed for the study and demonstration of various treatment methods or schemes. This facility will be constructed on the grounds of an operational dairy and will receive for treatment animal wastes and storm water runoff from a cattle holding area as well as wastewaters from a milking parlor and a milk processing and bottling plant. Altogether, six methods of treatment will be evaluated and demonstrated with the facility, all based on biological processes. Complete records on relevant dairy operations will be kept and appropriate wastewater analyses will be performed to provide sufficient data to evaluate the effectiveness of each method of treatment investigated. In addition, facility construction, operation, and maintenance costs will be compiled and a cost analysis of the treatment system will be made. The project was initiated in December 1969 and will continue until September 1972.

2.1293, BIODEGRADABILITY OF TNT

J.M. ROSEN, U.S. Navy, Ordnance Laboratory, *Silver Spring, Maryland* 20910

Technical Objective: Investigate the feasibility of microbiological means of counteracting water pollution from explosive facilities.

SUPPORTED BY U.S. Dept. of Defense - Navy

2.1294, REVERSE OSMOSIS TREATMENT OF WASTEWATERS

R.T. SKRINDE, Univ. of Massachusetts, School of Engineering, *Amherst, Massachusetts* 01002

Removal of pollutants from water by reverse osmosis has great potential as a new, efficient, and economically feasible method of wastewater treatment. The process has been investigated primarily as a method of desalination of sea water, and only recently has any attempt been made to apply reverse osmosis to the treatment of municipal and industrial wastewaters.

The purpose of this research is to obtain data needed to evaluate and apply reverse osmosis as a process for the treatment of wastewaters. In particular, an improved understanding of the mechanism of separating organic materials from water is essential to development of more suitable membranes and better geometric design of reverse osmosis cells.

The objectives of this study are to: a. Obtain data essential to development of design parameters, including data on liquid diffusion rates, efficiency of separating organic pollutants, and cell operating characteristics for presently-available membranes utilizing waters containing selected organic and inorganic chemicals. b. Apply the above data in developing membrane separation techniques for advanced treatment of organic industrial wastes and municipal sewage. In addition to the development of membranes and cells specific to wastewater treatment, this phase of the investigation will consider systems in which reverse osmosis

may be utilized in conjunction with such chemical additives as activated carbon and polyelectrolyte coagulant aids. The systems developed will be tested on municipal sewages and industrial wastes.

2.1296, STUDIES IN FOAM SEPARATION AND RELATED TECHNIQUES
B.L. KARGER, Northeastern University, Graduate School, *Boston, Massachusetts* 02115

The distribution factors of several metal ions have been measured as a fuction of HCL concentration for a foam separation process. Measurements have been performed on a recycling batch foaming apparatus. Using a cationic surfactant, hexadecyltrimethylammonium bromide, maxima in distribution factors have been obtained at IN HCL for Hg and 8N HCL for Fe. Thus, by adding controlled amounts of HCL selective removals of metallic species can be achieved. It is also worth pointing out that distribution factors have been measured as low as 10 to the minus 12th power M metal ion concentration, and results indicate that foam separation techniques are effective at this level. These studies can be of value in deciding conditions necessary for use of foam separation techniques as in-plant clean-up procedures for industrial wastes. Studies are also underway in examining the extraction mechanism involved in solvent sublimation. The results of this study will be presented at a later date.

2.1299, MATHEMATICAL MODEL OF THE ELECTRODIALYSIS PROCESS FOR ADVANCED WASTE TREATMENT
J.D. SMITH, Process Research Incorporated, *Cambridge, Massachusetts* 02142

The objective of this contract is to develop a mathematical model of the electrodialysis process for use in preliminary design and simulation of wastewater treatment processes.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1300, SELECTIVE NITRATE AND PHOSPHATE REMOVAL
J.D. SMITH, Process Research Incorporated, *Cambridge, Massachusetts* 02142

The objectives of this proposed research program are: 1. To investigate an ion exchange membrane system for selective removal of nitrates and phosphates. 2. To determine the initial feasibility of this system. 3. To develop a preliminary design rationale for the proposed system, and 4. To estimate the potential effectiveness and economics of such a system in waste water nutrient removal applications.

A laboratory scale nitrate and phosphate removal system, using exchange membranes will be constructed. Nitrate and phosphate transport rates will be determined with this system, using commercially available anion exchange membranes. Parameters which will be examined will include: 1. Driving force, or chemical affinity. 2. Concentrations. 3. Flow velocity, and 4. Membrane type.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1301, COMMUNITY ADOPTION OF WATER RECYCLING SYSTEMS
R. KASPERSON, Clark University, Graduate School, *Worcester, Massachusetts* 01610

Within the last decade, research has demonstrated that recycling of reclaimed wastewater is a technological feasible and an economical viable alternative in the provision of domestic water supply. With the projected demand for water expected to exceed supply by the year 2000, especially for many of our large metropolitan areas, the alternative of recycling can contribute significantly toward alleviating the scarcity of water. To date, very few communities have chosen to develop a recycling system. And, in most places planning for improved urban water supplies, recycling is virtually absent from the discussion of alternatives. However, discussions of future water supply problems assume a widespread adoption of recycling.

Identification of the potential problems and prospects of community adoption of recycling systems constitutes the focus of this research project. The role of information and perception, and the type of political structure will be analyzed as they relate to the adoption process. An intensive study of eight cities, each concerned with the immediate provision of water supply, will be completed focusing upon: 1) the type of political framework in which water supply planning is formulated; 2) the perception of the range of choice and attitudes toward recycling by consumers, public officials, consulting engineers, and public health officials, and the bases for the identified perceptions; and, 3) the formulation of opportunities directed toward the encouragement of the consideration of water recycling systems.

2.1302, PILOT-SCALE STUDY OF IMPROVED PHOSPHATE REMOVAL BY MODIFIED ACTIVATED SLUDGE PROCESS
G. REMUS, Detroit City Government, *Detroit, Michigan*

The primary objective of this project is to determine the most suitable and economically feasible treatment process for the continuous removal of at least 80 per cent of soluble phosphates from the wastewater of a large municipality. The process must also be compatible with treatment for removing a high percentage of suspended solids, phenols, oils, and bacteria, and reducing BOD.

By resticting the supply of phosphates to Lake Erie, the growth of algae in the Lake may be slowed and the life of the Lake lengthened.

The most promising tests will be subjected to large-scale pilot plant studies to determine their suitability for use in large treatment plants. Of importance will be the follow-through on sludge disposal to determine the adequacy of sludge thickening, dewatering, and incinerating devices for delivering the phosphates taken up by the sludge, and to keep them from the plant effluent.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1303, THE CHARACTERIZATION OF SOLUBLE PHOSPHORUS COMPOUNDS IN BIOLOGICAL WASTE TREATMENT PROCESSES

F.M. DITRI, Michigan State University, School of Engineering, *East Lansing, Michigan* 48823

The soluble phosphorus compounds existing in waste flows through the treatment plant are usually considered to be in the form of organic phosphates and simple or condensed forms of the oxyanion, while these complex compounds such as the hydroxyphosphates, hydroxyapatites and apatities, which may be present, are generally considered. Furthermore, data on the hydroysis transformation of these complex phosphorus compounds in an activated sludge environment are not known with any certainty. Since the trend in waste water renovation today is clearly toward tertiary treatment the influence of these complex phosphorus compounds needs to be established since the solubilities of several of these compounds are normally exceeded several-fold in the process stream.

This proposed research will be directed toward the in situ qualitative and quantitative identification of the soluble phosphorus compounds existing in the process streams of prototype units of the activated sludge processes. The various forms of phosphorus in a filtered sample of the waste water will be separated on thin-layer chromatographic plates and the respective concentrations determined by optical scanning of the thin-layer plates with a densitometer.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1304, THE RATE OF NITROGEN AND PHOSPHORUS STRIPPING FROM SEWAGE LAGOONS BY AQUATIC ANGIOSPERMS

C.D. MCNABB, Michigan State University, Graduate School, *East Lansing, Michigan* 48823

Stripping of nitrogen and phosphorus from organic effluents or from sections of stream overburdened with these plant nutrients continues to be a major problem in relation to degradation of the aquatic environment. While practical physio-chemical processes for use in treatment facilities have recently been improved to a degree, significant quantities of these elements are consistently discharged through installations of the most modern design to lakes and streams. It has been obvious to ecologists for decades that the harvest of primary producers would remove nutrients and a nuisance from eutrophic habitats, and possibly result in an economic gain from the harvest. Some impressive efforts have been expended to identify the most efficient system for the harvest of planktonic species of algae. Little effort has been applied to the aquatic angiosperms for the same end.

The objective of this research is to determine the rate at which nitrogen and phosphorus are removed by selected species of aquatic angiosperms from water in sewage oxidation ponds during different seasons of the year. Species of Cabomba, Ceratophyllum, Myriophyllum, and Ranunculus will be used. Groups of each type of plant will be acclimated to a pre-absorption physiological state in laboratory troughs. Light and temperature regimes close to those of the season in a nearby sewage oxidation pond will be maintained in the troughs. Concentrations of nitrogen and phosphorus in the tissues of experimental lots of plants will be fixed by controlled bleeding of medium into the troughs. Lots will be submerged for varying periods of time in the sewage pond. Tissue analyses will be made upon removal, and time- related changes in the levels of the nutrients determined. Environmental parameters will be monitored in the laboratory and field. Project begun in fiscal year 1969; to be completed in fiscal year 1970.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1305, AN EXPERIMENTAL PROGRAM ON WATER QUALITY MANAGEMENT

UNKNOWN, Michigan State University, Graduate School, *East Lansing, Michigan* 48823

Michigan State is planning to develop a series of lakes and ponds stocked with aquatic plants and fish to serve as 'living filters' for sewage effluent. Some of the water in various stages of purification, will feed areas planted with trees, grass, crops, and garden plants. Most of it will be retained in the system and allowed to replenish the water table, which has dropped 200 feet since 1945.

Part of the 300-acre area will be used as a public park, with boating, fishing, and other recreational facilities. Research and training will be carried out in hydrology, biology, argonomy, fish culture, and other sciences, and social and economic studies undertaken to evaluate the effectiveness of the system for community water quality management.

SUPPORTED BY Rockefeller Foundation - New York, N.Y.

2.1306, HYDROLOGY OF RIVER-BASED RECREATION

G.E. HENDRICKSON, U.S. Dept. of the Interior, Geological Survey, *Lansing, Michigan* 48933

Purpose:- This research is part of the program of water resources investigations conducted by the U.S. Geological Survey in cooperation with the State of Michigan. To analyze the hydrologic factors related to use of cold-water rivers in a glacial terrain, to provide guidelines for assessing the potential recreational value of such rivers, and to determine how development by man in the watersheds affects the recreational value of the streams.

Methods: On the basis of streamflow and water quality records, geology, topography, and amount of development, select representative rivers in northern Michigan, assemble information regarding streamflow characteristics, stream morphology, water temperature, ground-water levels, and areas of ground-water discharge. Obtain information on recreational potential of rivers, including fish populations and present and future use for fishing, boating, and camping. Interpret relationships of recreational uses to hydrology of the watershed. In developed watersheds obtain information on surface and ground water withdrawals, disposal of sewage and other wastes, regulation by dams, and indirect controls by timber-cutting and other changes in land use in the watersheds. Report on relationships of characteristics of streamflow, water quality, and stream morphology to river-based recreation.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.1307, DEMONSTRATION OF THE RECONDITION AND RE-USE OF ORGANICALLY CONTAMINATED BRINES FROM CHEMICAL PROCESS INDUSTRIES

C.J. PINAMONT, Dow Chemical Company, *Midland, Michigan* 48640

Project objectives and description of work: 1) Develop and demonstrate a charcoal adsorption process for the treatment of process wastewater from a phenol manufacturing plant. 2) Demonstrate the requirements for by-product recovery from the subject wastewater, which will include the net recovery of both organic and inorganic. Phenol and acetic acid will be removed from a sodium chloride brine. 3) Demonstrate wastewater re-use on an engineering scale. Process will recondition 100 gpm of wastewater. 4) Research and develop methods for a) the regeneration of adsorption materials to be used in the proposed process, and b) establishing requirements and limitations on the use of the renovated brine wastewater for chlorine-caustic production.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1308, PHOSPHATE REMOVAL BY BIOLOGICAL PROCESS

T.L. HENNESSEY, Trenton City Government, *Trenton, Michigan* 48183

2. WATER QUALITY

The purpose of this project is to develop a modified form of the activated sludge processes in which soluable phosphates are removed by natural biological processes from waste water and contained in the sludge withdrawn from the treating units. Phosphates will be removed from the liquid discharged from sludge dewatering either chemically or physically. Pilot plant operation shall establish the design criteria for the new secondary plant to be put into operation by November 1, 1970.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1309, PILOT PLANT INSTALLATION FOR USE OF FUNGI IMPERFECTI ON VEGETABLE WASTES

W.R. BROSZ, Green Giant Company, *Le Sueur, Minnesota* 56058

The use of fungi imperfecti for the treatment of liquid waste streams from the vegetable processing industry has been investigated by North Star Research and Development Institute in the laboratory. They have been successful in reducing starch waste with a B.O.D. of 3,200 down to 40 ppm. in a twenty hour residence time by continuous fermentation with successful removal of mycelium.

The presently proposed program is aimed at determining whether the effectiveness of fungi imperfecti can be realized in a pilot scale installation at a plant site. It is proposed that two 7,500 gallon aerated systems be tried. One would be an aerated lagoon and the other an aerated ditch. These would be installed at Green Giant's corn and pea processing plant at Glencoe, Minnesota. Data and observations will be gathered to assure that a stable fermentation cycle is achieved, to establish suitable start-up procedures, to compare fungi imperfecti with uninoculated aerated lagoons (to be installed and operated by Green Giant), to determine the usefulness of lagooned wastes as feed to the fermentation, and to aid in subsequent scale up. Other objectives are to further study aeration requirements, to determine the effects of flow patterns on the success of the fermentation, and to study filtration and drying problems.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1310, DEMONSTRATION OF THE CHANNEL AERATION PROCESS IN TREATMENT OF SEWAGE

H. BAUER, State Dept. of Health, *Minneapolis, Minnesota* 55414

The purpose of the project is to demonstrate the efficiency of the channel aeration process of sewage treatment on the removal of plant nutrients such as phosphate and bound nitrogen, and the removal of Salmonella and enterovirus from the incoming sewage. The effect of the treated effluent on algae and other aquatic plant growth in the receiving lake will be studied.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1311, FLOCCULATION AND CLARIFICATION OF MINERAL SUSPENSIONS

I. IWASAKI, Univ. of Minnesota, School of Mineral Engin., *Minneapolis, Minnesota* 55455

The clarification of the plant effluents from mineral processing operations is becoming a major concern of the iron ore industry of Minnesota. In a recent test program on flocculation and clarification of iron ore slimes and taconite tailings using lime and starch as flocculants, a complex relationship among pH, calcium ion and starch concentrations, size distributions, and flocculation, clarification and filtration behavior has been noted. Not only for efficient utilization of the flocculating agents on the settling and clarification of the mineral suspensions, but also for minimizing the pollution of the effluent by these reagents, it is desirable to formulate the nature and extent of their adsorption and to correlate with the flocculation and clarification behavior of some pure minerals and their mixtures of interest to the iron ore industry. Quartz and goethite of several different size distributions have been chosen for the investigation. The surface properties in the presence of these flocculants are being studied using the streaming potential technique to provide further insight into the flocculation behavior of these minerals. Different types of polymeric flocculants are also being included to study the effect of their chemical constitution.

The project commenced on January 1, 1969 and will be completed on September 30, 1970.

2.1312, NITRIFICATION AND DENITRIFICATION OF WASTE WATER

W.K. JOHNSON, Univ. of Minnesota, School of Engineering, *Minneapolis, Minnesota* 55414

The objective of this project is to conduct small-scale continuous flow pilot plant investigations to investigate nitrification in the activated sludge process and denitrification for the purpose of removing nitrogen from wastewaters. Several flow patterns will be investigated including a staged operation with nitrification and denitrification used alternately. A synthetic milk waste will be used as the raw waste feed to the pilot plants. No results of the investigations are available at this time. It is planned that larger scale demonstration plant tests using domestic sewage will also be conducted during the coming year.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1313, REMOVAL OF COLLOIDAL MATTER FROM WASTE WATER

W.J. MAIER, Univ. of Minnesota, School of Engineering, *Minneapolis, Minnesota* 55414

This research program is designed to provide a more basic understanding of the removal and metabolism of organic colloids from waste waters as a result of biological activity. The experimental work is set up to obtain information on both the mechanism and the rates of removal of various organic colloids. The program covers a broad range of operating variables. Experiments are being carried out in two types of reactors; the film flow reactor simulates conditions where mass transfer is a rate limiting factor whereas the well mixed reactor approaches conditions where mass transfer is rapid and metabolism is the rate limiting factor. A variety of colloidal substrates is being tested over a broad range of operating conditions, namely, protein, starch and lipid.

The final objective is to develop theoretically sound rate equations to describe the effects of process variables on the rates of removal of various organic colloids. This information is to be used in correlating and interpreting plant test data and day to day variations in conventional biological treatment processes.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1314, TREATMENT OF WASTES USING PEAT, AND PEAT IN COMBINATION WITH SOIL

R.S. FARNHAM, Univ. of Minnesota, School of Agriculture, *Saint Paul, Minnesota* 55101

To study the adsorption phenomenon of peat and peat-sod mixtures, both in the field and laboratory. The object is to reduce phosphates and organic loading of waste water.

The mechanics of the filtering process are being studied as well as addition of chemicals to increase efficiency of the phosphate and B.O.D. reduction by using peat.

Work is being done both at the laboratories of the University of Minnesota and in the field in St. Louis County, Minnesota, at Wilderness Valley Farms, Zim; Sewage Disposal Plant, Virginia, Minnesota. The first year of this project started April 1, 1969. Work to be completed by March, 1971.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

2.1315, EFFICIENCY AND ECONOMY OF POLYMERIC SEWAGE CLARIFICATION

K.D. LARSON, South St. Paul Sew. Disp. Com., *South Saint Paul, Minnesota* 55075

The project objectives are to determine the increased purification attainable by treating industrial wastes (packing house), sanitary sewage, combined sanitary sewage and storm waters or combinations of such wastes with polyelectrolytes and floc 'weighting agents.' Design parameters for the degree of treatment to be expected will be established on the combined city sewage

and industrial wastes, on the city wastes for both 'dry weather' and 'wet weather' flows, and on the industrial wastes separately. Physical and chemical characteristics of the sludge obtained as a result of this treatment procedure will be established.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1316, FORAGE CROP IRRIGATION WITH OXIDATION POND EFFLUENT
J.B. ALLEN, Mississippi St. University, School of Agriculture, *State College, Mississippi* 39762

This study will investigate the feasibility of using oxidation pond effluent for the irrigation of high yielding forage crops in Mississippi. The objectives are: 1. To determine the practicality of disposing of oxidation pond effluent through irrigation of forage crops. 2. To investigate the effect of oxidation pond effluent on forage crop yields. 3. To determine the effect of oxidation pond effluent on soil nutrients and on runoff water from the plots.

The field study will be carried out using effluent from a one acre oxidation pond which serves a residential area. A series of test plots will be prepared for furrow irrigation and planted in a high yielding sudan grass-sorghum hybrid. Various amounts of oxidation pond effluent and ordinary lake water will be applied to the plots. The weight and quality of the forage from each plot will be determined. At various times during the growing season the effluent from the oxidation pond and the storm runoff from the test plots will be analyzed for BOD, coliform bacteria, nitrogen, and phosphorous. The ground water level at the test plot area will be monitored.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1317, POLLUTION EFFECTS DETERMINATION
L.R. BROWN, Mississippi St. University, Inst. for Space Env. Sci. Eng., *State College, Mississippi* 39762

The purpose of this effort will be to evaluate the effect of RP-1 and trichloroethylene on the stabilization of sewage, and to relate these findings to the operation of sewage lagoons in terms of their effect on the efficiency of operation.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

2.1318, EVALUATION OF CURRENT TECHNIQUES OF NUTRIENT REMOVAL FROM WASTE WATERS
A. SHINDALA, Mississippi St. University, School of Engineering, *State College, Mississippi* 39762

As a result of an extensive research program, techniques for removing a high fraction of nutrients, mainly nitrogen and phosphorus, from waste effluents have already been developed. However, such information is so widely scattered through the literature that it is not readily available to those concerned with the problem.

The main objective of the proposed study is to compile and evaluate the available information on current techniques for removing nutrients from waste waters with emphasis on type of treatment (physical, chemical, biological or any combinations); economics (capital and operating costs); efficiencies; and applications.

The goals of the proposed study will be achieved through a comprehensive search of the literature, questionnaires and personal interviews with scientists, engineers and other investigators.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1319, ORGANIC WASTES AS A MEANS OF ACCELERATING RECOVERY OF ACID STRIP-MINE LAKES
D.L. KING, Univ. of Missouri, School of Engineering, *Columbia, Missouri* 65202

This proposed research is aimed at evaluating the potential for accelerating recovery of acid strip-mine lakes by the addition of waste organics such as domestic sewage sludges and animal manures. Specifically, this study plan calls for determination of the rate of formation of bicarbonate--carbonate alkalinity in acid strip-mine lakes by carbon dioxide release associated with bacterial utilization of organic wastes. The establishment of such a carbonate buffer system is required to provide the available carbon source necessary to support significant amounts of algal production as well as to neutralize the mineral acidity common to such lakes.

This study will be conducted in laboratory microcosms of acid mine water to which varying amounts of raw sewage sludge will be added. Measurement paramaters to evaluate the rate of recovery are inorganic and organic carbon content, titrametric buffer determinations, pH, and chlorophyll content.

Results of this study will allow calculation of the amount of organic waste which should be added to acid strip-mine lakes to yield a significant degree of recovery.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1320, RESEARCH INITIATION - LAKE POLLUTION BY INTERNALLY PRODUCED ORGANICS
J.T. NOVAK, Univ. of Missouri, School of Engineering, *Columbia, Missouri* 65202

The failure of man to control his natural environment is due to a lack of understanding of the complex systems which govern this environment. It is the purpose of this research to seek further insight into some of the relationships which govern plant productivity in lakes. Such information must be used as the basis for waste treatment plant design if the environment is to be most beneficially managed. In this study the production rate and identification of complex acidic organic materials produced as intermediates during anaerobic degradation of algae materials is to be determined. These degradation intermediates can effect productivity by two methods, increasing the concentration of nutrients in solution and increasing the availability of these nutrients for plant use. Identification of soluble organic constituents produced during anerobic metabolism will comprise a major portion of this study. The molecular weights, acidity and chemical composition of these organics will be determined.

SUPPORTED BY U.S. National Science Foundation

2.1321, AN INVESTIGATION OF LIGHT-CATALYZED CHLORINE FOR TREATMENT OF WASTE WATER
A.F. MEINERS, Midwest Research Institute, *Kansas City, Missouri* 64110

The purpose of the study is to investigate the effect of light on rate and extent of chlorine oxidation of a variety of organic materials typical of those found in waste water and representative samples of effluent from biological treatment plants; to determine the capabilities of light-catalyzed chlorine oxidation and to make an economic analysis of the feasibility of such treatment.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1322, WATER GEOCHEMISTRY OF MINING AND MILLING RETENTION PONDS IN THE 'NEW LEAD BELT' OF SE MISSOURI
E.A. BOLTER, Univ. of Missouri, School of Science, *Rolla, Missouri* 65401

The proposed research plan involves laboratory and field investigations directed at the determination of the removal processes of heavy metals from the waters of mining and milling retention ponds. The main approach in the investigation is to determine if the heavy metals are removed from the water as (a) precipitates, such as sulfides or carbonates, (b) by adsorption on clay minerals or (c) by uptake through organic matter, such as algae. In addition, the influence of organic flotation agents used in the milling processes on the transport of particulate matter will be investigated.

Field investigations: Water samples, samples of particulate matter and of organic material will be collected at several points in the ponds and at the outflow. The amount of particulate matter leaving the ponds will be determined. The retention time of the ponds will be investigated.

Laboratory investigations: The heavy metal content of pond water, suspended particulate matter and organic material will be determined by atomic absorption spectrophotometry. The mineralogy of particulate matter in the ponds will be determined

by X-ray analysis. The influence of organic flotation agents on the suspension time of particulate matter will be investigated.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1323, THE USE OF ANAEROBIC FILTERS FOR THE RENOVATION OF ACIDIC WASTEWATERS
R.H. CLARK, Univ. of Missouri, School of Engineering, *Rolla, Missouri* 65401

The research proposed would investigate the use of anaerobic filters as a means of treating acidic wastewaters which are organically polluted. Laboratory completely mixed biological reactors are to be used to determine the steady state pH tolerance of anaerobic digestion using various typical acidified wastes and waste constitutents. Predictive and design equations for anaerobic filters treating these acidic wastes will be developed and then tested using laboratory anaerobic filters. Design and operational procedures and recommendations will be formulated during the final phase.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1324, A NEW APPROACH FOR WATER RECLAMATION - COMPLETE TREATMENT OF WASTE WATER BY PHYSICO-CHEMICAL PROCESSES
J.C. HUANG, Univ. of Missouri, Environmental Health Res Ctr, *Rolla, Missouri* 65401

The purpose of this research project is to investigate the applicability of using advanced physico-chemical processes for the complete treatment of primary effluents for reuse applications of several selected waste waters, ranging from regular domestic sewage to high strength, nonbiodegradable industrial waste. Particular emphasis will be placed on the evaluation of the treatment efficiency and performance characteristics in the operation of each process for various types of waste.

The proposed waste treatment scheme will include chemical coagulation and clarification, filtration, and carbon adsorption. Laboratory-scale units will be constructed for the operation of each treatment stage. Treatment efficiency will be determined on the basis of removals of organic materials, suspended solids, turbidity, phosphorus, nitrogen, and bacteria from waste waters.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1325, USE OF DOMESTIC WASTE GLASS FOR URBAN PAVING
W.R. MALISCH, Univ. of Missouri, School of Engineering, *Rolla, Missouri* 65401

Laboratory and field studies have been used to investigate the possible utilization of waste glass as aggregate in asphaltic paving mixtures. Mixtures satisfying standard paving design criteria have been designed using penetration grade asphalts and aggregates. Bonding of asphalt and glass in the presence of water can be greatly improved by the addition of hydrated lime to the mixture.

Glass asphalt mixtures can be placed and compacted using conventional construction equipment. Initial skid resistance for the field installation has been adequate but tests are continuing to assess long term changes in skid resistance.

2.1326, REMOVAL OF PHOSPHATES BY SORPTION ON ACTIVATED ALUMINA
K. PURUSHOTHAMAN, Univ. of Missouri, School of Engineering, *Rolla, Missouri* 65401

The proposed research is a laboratory investigation of the sorption method of removing phosphates from water using activated alumina, and its specific objectives are to evaluate the capacity of the activated alumina to sorb phosphates in the presence of other ions and to determine the effect of ionic concentration on the efficiency of the process. Studies will be conducted using three types of phosphate containing test water, deionized water, tap water, and secondary sewage treatment plant effluent. Jar tests and column studies will be made to determine the sorptive capacity of activated alumina under equilibrium conditions to evaluate phosphate removal under varying phosphate concentration, ionic strength, feed flow rate, and alumina bed depth, and to investigate the feasibility of regeneration of the used alumina.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1327, EFFECT OF SURFACTANT MICELLES ON METAL ION REMOVAL BY FLOTATION FROM METALLURGICAL WASTEWATER
R.L. VENABLE, Univ. of Missouri, Water Resources Research Ctr., *Rolla, Missouri* 65401

Pollution of our water resources is now recognized as a pressing national problem. Among the serious contaminants are heavy metal ions such as copper, nickel, zinc, and lead. The proposed work will be a fundamental study of a possible way of removing such metal ions from dilute aqueous solutions by flotation with surfactants. The behavior of heavy metal ions in the presence of surfactants is complex and little work has been done to elucidate this complex behavior.

It is proposed to determine the state of solution of metal ions at various surfactant concentrations by a combination of turbidity and surface tension measurements. This is necessary to an understanding of the flotation process because the flotation characteristics of free heavy metal-surfactant molecules would be expected to be different from that of such molecules when they are incorporated into the interior of aggregates of surfactant molecules called micelles, which would be still different from the flotation characteristics of precipitated heavy metal-surfactant particles.

As a further aid to understanding the flotation process, efforts will be made to disintegrate surfactant micelles to fragments with bursts of ultrasonic energy and observe the effects of this disintegration on the efficiency of flotation.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1328, REMOVAL OF METAL IONS BY FLOTATION WITH SURFACTANTS
R.L. VENABLE, Univ. of Missouri, Graduate School, *Rolla, Missouri* 65401

The nation's water resources are rapidly becoming seriously polluted and some of the very toxic contaminants are metal ions. If a way of removing these metal ions from solution could be developed which is more economical than present treatment methods, the technique would have potential as a means of reducing this pollution. The proposed study would be a fundamental investigation of the method called ion flotation which utilizes solutions of surface active agents or surfactants and which has potential as an economical treatment procedure.

The objectives of the proposed work are to make ion flotation studies on ions not previously investigated. The studies will attempt to determine what type of surfactant is most effective and what conditions of pH, surfactant concentration, and temperature are necessary for the method to be effective. An additional objective will be to study the effects of addition of surfactant on the state of solution and availability for flotation of the metal ions. These studies are to be correlated with the flotation studies as an aid to understanding the results obtained there.

2.1329, LIME-LIMESTONE NEUTRALIZATION OF ACID MINE DRAINAGE
L.G. KOEHRSEN, Peabody Coal Company, *Saint Louis, Missouri* 63102

This research project consists of the development of a full-scale plant for the neutralization of acid-mine drainage utilizing lime and limestone in series and in parallel. Interpretation of the operating data obtained in a manner that it may be utilized as a design basis at other locations where a neutralization facility is warranted.

The plan of operation includes research, design, construction and operation of a full-scale acid-mine drainage neutralization

plant for treating acidic discharges from the Will Scarlet Mine of Peabody Coal Company located near Carrier Mills, Illinois.

The immediate and long-range objectives of the proposed project include the following: 1. To add to current technology regarding techniques of neutralization of acid-mine drainage utilizing limestone alone and in combination with lime. 2. To design, construct and operate a full-scale neutralization plant to treat acidic discharges from the Will Scarlet Mine of Peabody Coal Compnay. 3. To develop through operation of the plant a workable and practical design of treatment units and techniques to optimize neutralization efficiency and minimize chemical and operating costs. 4. To extract design parameters from the operational data for application to efficient design of similar facilities at such locations where neutralization of acid-mine drainage is warranted. 5. To publish the background studies, operational information and final results in a form usable to all parties confronted with an acid-mine drainage problem.

This project was started during fiscal year 1969 and will be completed during fiscal year 1971.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1330, COLOR AND MINERAL REMOVAL FROM KRAFT BLEACH WASTES

R.L. SANKS, Montana State University, School of Engineering, *Bozeman, Montana* 59715

The purpose of project is to determine the economic potential of synthetic resins for the control of pollution from kraft bleach wastes particularly in reuse and recycle systems.

The optimum treatment system is expected to consist of lime precipitation followed by decolorization and partial demineralization with resins. Processes to be evaluated include sorption only and partial demineralization by the Duocat and Desal processes and possibly by the Sul-biSul process as well.

Date of completion is June 1972.

2.1331, MICROBIOLOGY OF ESTUARINE AND SHELLFISH POLLUTION

L.W. SLANETZ, Univ. of New Hampshire, School of Liberal Arts, *Durham, New Hampshire* 03824

Studies will be continued on the comparative efficiency of coliforms, fecal coliforms, fecal streptococci, and bacteriophages as indicators for the presence of salmonellae, enteric viruses, and other microbial pathogens in estuarine waters and shellfish. Sampling stations will be selected which meet sanitary standards for approved and conditionally approved shellfish growing areas. Attention will be given to procedures for the detection and use of bacteriophages as indicators of enteric virus contamination, and to methods for the enumeration or detection of salmonellae, pseudomonas, Vibrio parahemolyticus and other bacteria in estuarine water and shellfish. Emphasis will be given to factors which affect or procedures that may be effective for the decontamination or depuration of oysters and clams under controlled laboratory conditions using facilities in a new estuarine laboratory located next to the estuarine area under study. Naturally contaminated oysters and clams harvested from polluted areas and shellfish artificially contaminated with indicator bacteria, phages, salmonellae, and enteric viruses will be used for these studies. The efficiency of waste treatment plants for the elimination of indicator organisms and microbial pathogens in effluents discharged into estuarine waters and the impact of two new municipal treatment plants on the sanitary quality of these waters will be determined.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.1332, HYDROGRAPHY OF NEW YORK BIGHT IN RELATION TO OFFSHORE WASTE DISPOSAL

R.I. WICKLUND, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Highlands, New Jersey* 07732

Study the hydrography of the New York Bight with particular emphasis on conditions having a direct effect on the movements of waste disposal.

Measure and analyze temperature and salinity throughout the water column at 26 stations every two weeks, and release 300 sea bed drifters and drift bottles once a month.

Establish sta ons, utilizing sub-surface buoys, at six locations equipped with thermographs located at the bottom and in midwater. Supplemental buoy stations may be added to verify hypothesis developed from interpretation of regular station data.

Temperature, salinity, and density determinations to be plotted on horizontal and vertical profiles and drifter, current meter, and thermograph data processed and analyzed by computer techniques.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1333, RECLAMATION OF METAL VALUES FROM METAL-FINISHING WASTE TREATMENT SLUDGES

W.V. TURNER, Metal Finishers Foundation, *Montclair, New Jersey* 07043

The nature of the waterborne wastes produced in metal-finishing operations is such that complex and costly methods have been needed to prevent the pollution of water by toxic compounds used by this industry. The specific steps involved in the treatment of these wastes vary considerably from installation to installation. However, the general treatment consists of: (1) separation of grease and oil; (2) reduction of chromates; (3) oxidative destruction of cyanides; (4) neutralization and liquid-solid separation; and (5) disposal of the sludge. The metals initially present in the wastewaters are precipitated as hydroxides during the treatment operations. The metal- bearing sludes are difficult to handle and their final disposal often is the most troublesome and costly aspect of the treatment of metal- finishing wastes. These sludges are a potential source for pollution of surface and ground waters because of the highly reactive nature of the metal hydroxides which they contain.

Preliminary surveys indicate (1) that the removal of metals from these sludges may simplify disposal and diminish potential hazards, and (2) that the reclamation of these materials (nickel, copper, cadmium, etc.) may significantly reduce the net cost of sludge disposal. The current program is concerned with supplementing the existing information by specific and numerous in-plant studies, determining whether metal reclamation is as worthwhile as is now suspected, and evaluating processes that would be applicable to the recovery of these metals and/or to the improvement of disposal methods.

The program is being conducted at the Columbus Laboratories of Battelle Memorial Institute. It is anticipated that the work at Battelle will begin in November, 1970, and will be completed in January, 1972.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.1334, AN INVESTIGATION OF TECHNIQUES FOR THE REMOVAL OF CHROMIUM AND CYANIDES FROM ELECTROPLATING WASTES

W.V. TURNER, Metal Finishers Foundation, *Monclair, New Jersey* 07043

The Metal Finishers' Foundation will conduct a two-phase research and demonstration project on methods for economically treating cyanide and chromium wastes from small plating shops. Phase I will include (a) a 'State of the Art' review of recovery techniques, (b) accumulation of data on waste stream compositions, (c) selection of techniques for bench scale study and selection of extractants and complexing agents, (d) bench scale experimental investigation of selected techniques, and (e) evaluation of the test results and preparation of recommendations. This phase will require one year.

Phase II will consist of (a) the design of the process and the processing equipment, (b) acquisition and installation of the equipment in an electroplating plant, (c) operation of the demonstration plant to accumulate data, and (d) the evaluation of the data and preparation reports.

The work will be performed by subcontract to the Battelle Memorial Institute at Columbus, Ohio. Various treatment methods, including liquid-liquid extraction, ion flotation, and precipitate flotation, will be investigated and compared.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1335, PROCESS CONTROL MODEL FOR OXYGEN REGENERATION OF POLLUTED RIVERS
B. DAVIDSON, Rutgers the State University, School of Engineering, *New Brunswick, New Jersey* 08903

The proposed research plan involves the application of lumped and distributed parameter optimal control theory as a tool in the systems analysis of a new class of in situ treatment alternatives for polluted rivers and streams. The control variables are instream aeration, biochemical oxygen demand distribution, nuclear power plant cooling water distribution, and dilution water distribution from a reservoir. All controls are distributed continuously in space and time coordinates and optimized with respect to an objective function of the cost functional type with weighted energy constraints. For the lumped parameter cases, Pontryagin's Extremum Principle will be invoked, whereas for the distributed systems, a spatially discretized schema will be used in conjunction with Pontryagin's method in order to obtain optimal solutions.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1336, REMOVAL OF PHOSPHATE FROM WASTE WATER BY ALUMINUM AND IRON
P.H. HSU, Rutgers the State University, School of Agriculture, *New Brunswick, New Jersey* 08903

Results from previous studies indicate that the effectiveness of aluminum and iron to precipitate phosphate from solution drastically varied with experimental conditions. Three subjects will be covered in this proposed project to continue the investigation on the factors that govern the optimum conditions of phosphate precipitation: 1. Effect of order of mixing reactants on the precipitation of phosphate by aluminum; 2. Effect of Casuper2plus and Mgsuper2plus on the precipitation of phosphate by aluminum; and, 3. Aging of iron solution and its effect on the precipitation of pnosphate.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1337, THE ORGANIC CONCENTRATION GRADIENT IN AN AERATION COLUMN
B.T. KOWN, Rutgers the State University, School of Engineering, *New Brunswick, New Jersey* 08903

The proposed research is to investigate those chemical and physical factors, in addition to operational variables and equipment geometries, which influence the organic concentration gradient in the bulk solution of an air bubble column containing waste water. The objectives of the proposed research are to determine the factors influencing the gradient and to evaluate its possible application to the removal of the pollutants from waste water.

The initial phase of the proposed study will be concerned with the determination of the relationship between the nature of foams generated by rising air bubbles in a bubble column and the nature of the pollutants in the waste. The studies are to be made by batch equilibrium-type experiments.

The second phase of the study will involve laboratory studies of the organic concentration gradient which resulted from stripping action of the rising air bubbles and deposit of concentrated pollutants at the liquid level by ruptured air bubbles. Equipment geometries and operational variables which influence the equilibrium concentration gradient will be investigated.

The final phase of the study will be devoted to the evaluation of the possible application of the concentration gradient in the separation of organic pollutants from waste water. The application will be considered in two areas; one in which the pollutants are directly separated by removing the organic-rich-surface liquid, and the other in which the gradient is applied to improve the foam fractionation process.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1338, REMOVAL OF BOD AND NUTRIENTS BY BIOLOGICAL SLIMES
W.N. TORPEY, Rutgers the State University, Graduate School, *New Brunswick, New Jersey* 08903

To establish as completely as possible the maximum efficiency, basis for design, and economy of the biological rotating disc process. The system basically exploits the activity of the attached biological growths on closely specialized rotating discs alternately submerged in wastewater and exposed to air for high degree removal of organic matter and oxidation of ammonia nitrogen. When a series of such units are employed, sequential specialized populations become prevalent. The general approach is as follows: (a) to evaluate the effect of treatment efficiency of stressing the hydraulic and organic loads, (b) to define the relationship between the detention period, surface area concentration, and disc rotational velocity on the ability of the pilot plant to take loads without sacrificing treatment efficiency.

Pilot work performed at Jamaica Long Island Waste Treatment Plant.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1339, A CONCEPTUAL STUDY OF THE DISTRICT OF COLUMBIA BIOLOGICAL TREATMENT PILOT PLANT
J. ROSE, Burns & Roe Incorporated, *Oradell, New Jersey* 07649

To perform a study to develop the concept of the District of Columbia Biological Treatment Pilot Plant in accordance with the requirements set forth herein: I. Study Criteria A. Evaluate the process layout and hydraulic requirements of the two train (100,000 gpd per train) biological treatment pilot plant as described in the attached specification for installation at the District of Columbia Water Pollution Control Plant. B. Develop a sludge disposal system for the above pilot plant which includes: 1. Sludge dewatering systems a. vacuum filtration b. centrifugation c. experimental dewatering 2. Sludge incineration C. Prepare functional process layout for two larger pilot plants based on the design criteria and flexibility in above D. C. pilot plant and including disposal facilities for plant sized with: 1. Two nominal 250,000 gal per day treatment trains 2. Two nominal 500,000 gal per day treatment trains D. Furnish a cost estimate for the (100,000 gpd/train) pilot plant in A above.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1340, DEEPWATER PILOT PLANT ENGINEERING AND INTERCEPTOR FEASIBILITY STUDY
P.J. WEBBER, Delaware River Basin Comm., *Trenton, New Jersey*

Studies have indicated the potential economic, technical, and other advantages which can be realized from the construction of a single regional treatment facility at Deepwater, Salem County, New Jersey to solve the liquid wastewater treatment problems of 10 major industries, and the adjacent municipalities in Salem and Gloucester Counties along the Delaware River Estuary. Industrial wastes include pesticides, dyes, heavy metals, plastics, solvents phenols and other refractory chemicals.

A pilot plant is operative at the site of the regional facility to determine treatability characteristics, develop cost and design criteria for a full scale facility, test methods of secondary and advanced waste treatment and provide data to base on equitable cost apportionment system.

Wastes are being hauled by tank truck to the 50 gpm pilot plant. Currently, BOD removals are in excess of 90% and there are similar removals for heavy metals (as a result of a neutralization unit) and phenol.

SUPPORTED BY Delaware River Basin Comm. - Washington

2.1341, BRINE DISPOSAL DESIGN METHODOLOGY FOR ADVANCED WASTE TREATMENT
N.N. GUNAJI, New Mexico State University, School of Engineering, *Las Cruces, New Mexico* 88001

This investigation proposes to estimate reasonable limits of accuracy required for brine evaporation rates. It is also proposed to determine what effect the composition and concentrations of advanced waste treatment brines have on evaporation rates and pond design. Further, this research will be conducted to optimize the size and number of ponds necessary for effective disposal. The investigation will also clarify and evaluate methods for brine evaporation rate prediction, estimate accuracies, and recommend further refinements for predictve methods.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1342, PERFORMANCE OF INTERMITTENT SAND FILTERS
L.J. HETLING, State Dept. of Env. Conserv., *Albany, New York* 12205

To determine by controlled condition the extent to which grain size and uniformity coefficients affect the performance of intermittent sand filters.

Observation on the quality of influent to and effluent from the filters for a period of three months will yield valuable information which, coupled with a research of the literature, will afford sound conclusions in the following areas: 1) Affect of grain size and uniform coefficient upon the performance of the filters. 2) For any one filter media the affect of retention time upon performance. 3) The affect of filter use upon removal. 4) Removal of phosphorous and nitrogen by filter.

An extensive review of the literature has been made and a detailed experimental program set up. Construction of the experimental setup is expected to be completed by late spring of 1970 with the actual filter run being carried out during the summer.

SUPPORTED BY New York State Government - Albany

2.1343, TREATMENT NEEDED BY SEWAGE BEFORE INJECTION-WELL RECHARGE
L.J. HETLING, State Dept. of Health, *Albany, New York* 12208

A study to investigate the mechanism of clogging and its reduction to increase the recharge capacity of the injection well. Various methods of tertiary treatment were used (rapid sand filtration, diatomite filtration, carbon filtration), including degasification, chlorination and the application of bivalent ions, to produce an optimum effluent for injection.

The distance that various constitutents of sewage travel through saturated soil was also investigated by continual observations of the water quality in the observation wells. The project began in 1964 and was completed in mid 1969. The final project report has been received by the New York State Department of Health.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1344, DESIGN OF WASTEWATER TREATMENT SYSTEMS TO SATISFY EFFLUENT QUALITY REQUIREMENTS BASED ON INTENDED USE
A.W. LAWRENCE, Cornell University, School of Engineering, *Ithaca, New York* 14850

It is the objective of this study to have a 'fresh' look at wastewater treatment processes and systems in light of the growing interest in the reclamation of wastewaters as a 'new' source of water. This fresh look or reevaluation of wastewater treatment technology will be directed towards: 1) a review of the intended uses for reclaimed waste waters and determination of the quality requirements associated with each use.

2) a reevaluation of existing wastewater treatment processes and systems in the context of expected future performance criteria, i.e., effluent quality requirements.

3) examination of new processes or new combinations of existing processes in an effort to develop treatment methodology capable of satisfying effluent quality requirements which are not presently attainable.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1345, ADAPTATION BY MICROBIAL POPULATIONS
N.C. DONDERO, State University of New York, School of Agriculture, *Ithaca, New York* 14850

Selected experiments on enzyme adaptation and repression have been made with pure cultures and mixed populations of microorganims derived from activated sludge for the purpose of determining the physiological and nutritional homogeneity or heterogeneity of the populations transforming aromatic materials and other carbonaceous substrates.

The analysis of the populations have been made previously by enumeration and replica-plating on a series of substrates planned to show the capabilities of the population to utilize the substrates present and to reveal shifts in the microbial population when they occur.

Similar analyses will be made of the microbial populations in the processes of sewage treatment and a potable water impoundment.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1346, TERTIARY TREATMENT OF ANIMAL WASTE WATERS
R.C. LOEHR, State University of New York, School of Agriculture, *Ithaca, New York* 14850

The objectives of the project are to evaluate feasible processes applicable to the removal of nitrogen, phosphorus, and color from animal wastewaters, especially intermittent, concentrated wastewaters. The study shall investigate biological-chemical treatment alternatives in attempting to discover the most effective treatment processes for dairy cattle and poultry waste waters. The study is not restricted solely to 'tertiary' treatment processes.

The processes are to be evaluated on a laboratory scale and will include aerobic biological treatment, precipitation, ammonia removal, and nitrification-denitrification. The project will cover a two year period starting from May 1969.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1347, ADVANCED WASTE TREATMENT FOR WATER RECLAMATION AND REUSE BY INJECTION
H.J. SIMINS, Nassau Co. Dept. of Pub. Works, *Mineola, New York* 11501

Nassau County is committed to a long-range program to demonstrate the feasibility of using water reclaimed from sewage-plant effluent to increase the available ground-water resources.

The objective of the project is to conduct studies of advanced waste treatment processes and to demonstrate that the reclaimed secondary effluent is suitable for reuse and injection into underground aquifers. The project will provide operating data on advanced waste treatment processes and allow optimizing the economics of the process. It will also demonstrate the effectiveness and reliability of advanced waste treatment as a method of providing water for reuse from secondary treatment plant effluent.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1348, WINERY WASTEWATER - CHARACTERIZATION AND TREATMENT
E. HAYNES, Widmers Wine Cellars Inc., *Naples, New York* 14512

This project includes the design, construction, and operation of a wastewater treatment system at Widmer's Wine Cellers, Inc., in Naples, New York. The operation phase of this project will include sampling and testing of the pressing season and processing season wastewaters to characterize the winery wastewaters. In addition, the project will include a study of the effectiveness of an aerobic biological treatment process on this type of wastewater.

The long-term activated sludge treatment process will be utilized to treat the winery wastewater. The study of this system will include a determination of the effectiveness in the reduction of the organic content of the wastewater. In addition, the use of

identical parallel systems will allow study of the effect of varying the nutrient levels in the wastewater on the effectiveness of the biological system. Other design parameters, including pH, will be varied to determine their effect on the plant operation.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1349, COORDINATED MANAGEMENT AND DESIGN OF METROPOLITAN AREA WATER SUPPLY AND WASTE WATER DISPOSAL NETWORKS - A LINKED SYSTEMS ANALYSIS

L. ZOBLER, Columbia University, Undergraduate School, *New York, New York* 10027 (C-1629)

A linked systems analysis is to be made of the water supply system and the waste water disposal system of metropolitan areas. The nature of the connectivity entities will be specified. System parameters will be identified and manipulated. A computer simulation model will be constructed and the water resource of the total will be maximized by an optimizing method. The model will be tested with data for the New York Metropolitan Region.

2.1350, THE PRODUCTION AND USE OF ACTIVATED CARBON FOR WATER RENOVATION IN KRAFT PULP AND PAPER MILLS

W.G. TIMPE, Saint Regis Paper Company, *New York, New York* 10017

This program is aimed at water renovation and recycle in Kraft pulp and paper mills based on effluent treatment using activated carbon. The program is designed to establish a firm technical basis for designing Kraft pulp and paper mill systems with drastically reduced water pollution and fresh water consumption at reasonable cost.

The program is organized in two parts: Part I: Develop technical and economic data on the treatment of various Kraft mill effluents with activated carbon and demonstrate on a pilot scale treatment systems incorporating activated carbon in a Kraft mill environment. Part II: Demonstrate production and activation of a carbon char produced from black liquor as a by-product of a process for the recovery of pulping chemicals concurrently under development. Other mill-site raw materials for activated carbon production will be investigated. Determine the economics of mill site preparation of activated carbon.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1351, PHOSPHORUS REMOVAL IN THE ACTIVATED SLUDGE PLANT

T.E. BRENNER, Soap & Detergent Association, *New York, New York* 10022

The overall objective of this project is to determine the feasibility of removing phosphorus in an activated sludge plant treating domestic waste water through chemical precipitation with aluminum ion and utilizing only the existing aeration and settling units of the plant.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1352, METAL REMOVAL/RECOVERY FROM POLLUTED WATER BY COMPLEXATION WITH LINEAR POLYELECTROLYTES

H.H. JELLINEK, Clarkson College of Technology, School of Science, *Potsdam, New York* 13676

This project is based on the observation that a polyacid and a suitable polybase in the presence of a metal ion form a complex-sandwich insoluble in water. The metal ion can be removed from this complex by small amounts of mineral acid; thus it can be recovered as a fairly concentrated solution. It has been shown by the applicant and co- workers that the synthetic polymer system polymethacrylic acid- polyethylen-imine complexes over 90% by weight of the following metal ions from aqueous solution (10 to minus the 2nd power to 10 to minus the 4th power : Cu, Zn, Cd, Cr207, Ni, Co, Fe and 70% w/w of Mg and Pb. This method can thus be applied in principle, to removal and recovery of metals from polluted waters especially of rinse waters of the electroplating industry. However, such a synthetic system is not economical enough from a financial point of view. Hence research has been initiated for a natural polymer system of sufficient efficiency. This research has led to a fairly efficient system i.e. alginic acid and gelatine. The amounts of metals recovered by this system are not as good as those by the synthetic polymer system. % w/w Cu 72, Zn 38, Cd 34, Cr 50, Ni 20.

A very efficient polymer has been found suitable for practical application in polygalacturonic acid (fully hydrolysed pectinic acid). It has the advantage that the insoluble metal complexes are formed by using this polymer on its own. Once the metal has been leached from the complex, it can be used again and again. The following weight percentages of metals were precipitated with polygalacturonic acid: Cu 98%, Zn 77%, Cd 80%, Ni 69%. It can also complex with these metals in presence of plating solutions (CrO3 and H2SO4). Thus, eventually, many polymer systems will be available which are suitable for various situations. In principle, the method is also applicable for producing potable water and for desalination.

It is anticipated, that in the second year, many more suitable systems will be found which will be studied in detail and that a beginning will be made to test these systems on actual solutions obtained from the metal industries. Thus, a number of processes will be worked out in detail, which will be suitable in practice for various metal industries.

2.1353, MARINE DISPOSAL OF FINE-GRAINED WASTE SOLIDS

M.G. GROSS, State University of New York, Marine Sciences Res. Center, *Stony Brook, New York* 11790

The project seeks to evaluate the sources, composition, and environmental impact of major sources of fine-grained waste solids (nonfloatable) commonly dumped in the coastal waters of North America. The New York Metropolitan Region is the primary area of concern owing to the large volume of diverse wastes commonly dumped in nearby estuarine and coastal waters. Particular attention is given to sewage solids, dredged wastes, and certain industrial wastes. Samples collected at the sources are analyzed to determine the physical and chemical composition. Selected waste disposal sites have been selected for study to determine the amount and composition of the deposits accumulating in them. These include portions of New York harbor, one area in Western Long Island Sound, and two sites in the New York Bight. Water quality parameters and characteristics of the benthic organisms in the area of active waste disposal operations have been under investigation.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.1354, BIOLOGICAL TREATMENT OF ACID MINE WATER

P.A. RICE, Syracuse University, Research Institute, *Syracuse, New York* 13210

A three-year study is proposed to test the feasibility and to gather basic process data on the treatment of acid mine water in an anaerobic biological reactor containing the species Desulfovibrio desulfoxidans. If initial experiments demonstrate the feasibility of biological treatment, a set of parametric experiments will be carried out to determine the relationships between the amounts of hydrogen, sulfate, ferrous, and ferric ions removed and the process conditions. Appropriate mathematical models will be developed to describe the relationships between variables and to indicate the mechanisms controlling the removal rate of ions under various operating conditions. These models will be useful in reactor scale up and in understanding the basic mechanisms of sulfate reduction.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1355, CARBON COLUMN OPERATION IN WATER TREATMENT

C. TIEN, Syracuse University, Research Institute, *Syracuse, New York* 13210

The main objectives of this work are: 1. To carry out a detailed study of the operation of the granular activated carbon process in waste water treatment. In particular, the study will center on investigation of the three major functions of the carbon column in this type of application, namely, (A) the removal of total organic carbon, (B) the filtering of colloidal and suspended matter, and (C) the growth of micro-organisms within the column and the resulting biological action. 2. To investigate the interrelationship among these three main functions, the possibility of promoting or suppressing any given function, and the resultant effect on overall column operation and effectiveness. 3. To obtain a mathematical model describing the overall column operation. The desired mathematical description must be reasonably adequate, but must have a simplicity commensurate with the accuracy of the experimental data and also with the requirement that it must be readily utilizable by the design and operating engineer.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1356, IMPROVE POLLUTION CONTROL BY REUSE OF PAPER MACHINE PROCESS WATERS
G. WACHTER, Champion Papers Incorporated, *Canton, North Carolina* 28716

This project is directed toward demonstrating the complete reuse of paper-machine process waters by removing these materials as stream pollutants. It is part of a long-term program to develop a method for essentially closed water use systems. The project will include: 1. Recovery of all usable materials from paper-making process waters. This work involves modifications to existing and new systems to increase recovery of paper making materials. Process-water effluent from this system will go to the treatment system. 2. Treatment of excess process water to allow its reuse in place of fresh water, thus greatly reducing the quantity of fresh water required for paper making. Coagulating chemicals and precipitating processes will be used. 3. Disposal of sludge, generated in the treatment process, in a non-pollutional manner. 4. Any excess water flow returning to the stream will be of a quality that it will not contribute to stream pollution.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1357, TEXTILE WASTE REDUCTION THROUGH RECOVERY AND REUSE OF SYNTHETIC WARP SIZES
C.E. BRYAN, Univ. of North Carolina, Graduate School, *Raleigh, North Carolina* 27607

Analysis of the effluents from a number of textile finishing plants have shown that 45-70% of the pollution potential, as measured by 5-day B.O.D., can be attributed to the desizing wastes. The basis of most warp sizes is starch which is readily biodegradable.

In recent years certain water-soluble, synthetic polymers, such as sodium carboxymethyl cellulose (CMC) and polyvinyl alcohol (PVA), have been proposed as warp sizes with low B.O.D. but, because they are considerably more expensive than starch, their use has been limited.

The objective of the work proposed here it to investigate the recovery and reuse of the synthetic warp sizes with the aim of developing an economically attractive process for pollution control. (Starch cannot be recovered and reused because it is degraded in the desizing operation). A batch type of recovery will be examined first and then, if it is successful, attempts will be made to develop a continuous process. Conventional wet-processing apparatus, available in the pilot-plant of these laboratories, will be used with only limited modification.

If insurmountable difficulties arise in reusing the recovered materials, a more restricted goal will be disposal by another procedure, e.g., burning or burying.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1358, WATER POLLUTION REDUCTION THROUGH RECOVERY OF DESIZING WASTES
C.E. BRYAN, Univ. of North Carolina, Graduate School, *Raleigh, North Carolina* 27607

Surveys have shown that desizing wastes contribute 45-70% of the BOD5 of the effluents from the scouring, dyeing and finishing operations in cotton textile mills. The annual use of such sizes amounts to more than 300-million pounds. Starch is the predominant warp size by far. Certain synthetic warp sizes, particularly carboxymethyl cellulose (CMC) and polyvinyl alcohol (PVA), with low BOD5 have been introduced in recent years, however, and their use may be expected to increase. The long-term effect of these synthetic materials on stream pollution is unknown as yet. The proposed research includes, but is not limited, to the following: 1. To investigate processes for the recovery of desizing wastes in solid or concentrated form suitable for final disposal. The wastes studied will be those from fabrics sized with carboxymethyl cellulose (CMC), polyvinyl alcohol (PVA), and starch. 2. To investigate processes for the recovery of desizing wastes in reusable form. Reuse, as a size, of the desizing wastes from starch is not possible, of course, since starch is degraded during desizing. 3. To obtain more complete data on the biodegradation of the synthetic warp sizes, CMC and PVA. This study is expected to give information on the fate of these materials in biological treatment systems and in receiving streams.

The methods of recovery will involve evaporation, precipitation and other suitable processes.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1359, AN ECONOMIC STUDY OF MUNICIPAL SURCHARGES ON INDUSTRIAL WASTES
J.A. SEAGRAVES, Univ. of North Carolina, School of Agriculture, *Raleigh, North Carolina* 27607

We will develop an operational theory of industrial response to sewage surcharges given the alternatives of in-plant waste reduction, discharge to city and flow augmentation. Using this theory and samples of firms within industries across time periods we will use regression to estimate elasticities of industrial response to surcharges and changes in water rates. These results will be compared with those implied by budgeting studies of the costs of in-plant waste reduction. The gains to society associated with use of surcharges will be estimated and publications will be prepared explaining the likely response of selected industries to surcharges and the social benefits. The costs of different monitoring systems will also be estimated and compared with the benefits to society in the light of different alternatives.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1360, WATER BALANCE IN SEWAGE STABILIZATION LAGOONS
G.O. FOSSUM, North Dakota State University, State Water Resources Inst, *Fargo, North Dakota* 58102

This project proposes to conduct field investigations and laboratory analysis aimed at determining the water balance for a sewage stabilization pond containing an appreciable loading of organic industrial wastes. It is also intended to trace lateral movement of seepage from lagoons, and its effect on the adjacent water table.

The water balance is to be determined by measuring influent and precipitation by meters and rain gages and comparing with effluent, evaporation, and seepage. Quantity of effluent discharged will be measured and evaporation losses determined from evaporating pans. Infiltrometers will be used to determine seepage from the lagoon bottom.

Observation wells surrounding the lagoon at varying distances are to be used for sampling ground water for laboratory analysis. Correlation with natural ground water in the vicinity will give indications of pollution and ground water travel. These wells will also be used for water table observations.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1361, OPERATIONAL DEMONSTRATION OF OXIDATION DITCH METHOD OF WASTE TREATMENT
H.M. KANESHIGE, Ohio University, School of Engineering, *Athens, Ohio* 45701

2. WATER QUALITY

The project objectives are (1) to determine design criteria for the oxidation ditches based upon experimental and analytical evaluation of a currently available dual plant; (2) to determine most desirable operational procedures for obtaining maximum performance; and (3) to obtain an effectiveness comparison between the oxidation ditch and the lagoon methods of wastewater treatment.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1362, REUSE OF WATER, DALLAS PROJECT
J.D. WEEKS, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Cincinnati, Ohio* 45213

This project is designed to help set new drinking water standards when domestic sewage is the source of water. In addition, this project seeks to develop automatic monitors that will assure the continued safety of the effluent.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.1363, PROCESS DEVELOPMENT FOR REMOVAL OF NUTRIENT MATERIALS FROM WASTEWATERS
E.F. BARTH, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

Develop processes that more efficiently remove nutrient materials such as nitrogen, phosphorus, and sulfur from wastewater effluents; before discharge to receiving water.

Biological populations are controlled by process modifications which enhance desirable reactions. Chemical additives which can simultaneously be used with the biological flora are also investigated.

Nitrogen: Currently nitrification is being controlled by a two-stage biological treatment. Carbon is removed in a high-rate activated sludge system with high sludge wasting; the effluent enters a nitrification stage which contains an enriched culture of nitrifiers. The enriched culture is a result of the nature of the feed, and separate sludge recycle systems in the two-stage process.

Biological dentrification of the nitrified effluent is possible by passing the effluent through an anaerobic system and the addition of methyl alcohol to force use of the nitrate oxygen. Again the enriched culture approach with separate sludge recycle is used in this unit process.

Sulfur: The sulfur cycle is to be also be investigated in this integrated process.

Phosphorous: The efficiency of phosphorus removal by biological systems can be increased by adding chemicals that form slightly soluble phosphorus compounds directly to the biological reactor. Several compounds have been investigated and aluminum appears to be the most satisfactory for several reasons. The combination of biological activity with chemical supplements offers more consistent control than the biological system alone.

2.1364, CONTROL OF MINERAL CONSTITUENTS IN WASTE WATER BY ELECTRODIALYSIS
C.A. BRUNNER, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

Electrodialysis has been shown to be a technically feasible method for removing a sufficient amount of the inorganic dissolved solids from municipal waste water to restore it to a quality suitable for direct re- use. Although the process will work on biological-treated municipal waste water which still contains refractory organics, membrane fouling is a problem. Membrane fouling results in a decrease in the degree of mineralization during operation. This problem has been found to be due to the growth of microorganisms on the membranes. Disinfection methods are being studied to find one that is practical. Residual organics will be removed by carbon adsorption prior to electrodialysis. It is necessary to determine the economic feasibility of the process by operating a pilot-scale unit at a municipal waste treatment plant for a sufficient time to determine membrane life and operating costs. An electrodialysis stack has been constructed and is being operated for treating 50 gallons per minute of waste water. About 40 percent of the gross inorganic material (total dissolved solids) in the water is being removed. The fraction of the feed being used for concentrating and electrode streams is 0.086 or less. Appropriate pretreatment studies are being conducted . During the operation, the fractional removal of gross inorganics and selectivity of the removal process for various ions is being measured. Pilot work is being performed at Lebanon, Ohio.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1365, REMOVAL OF SUSPENDED SOLIDS AND PHOSPHATE FROM A SECONDARY EFFLUENT BY ALUM COAGULATION AND DUAL MEDIA FILTRATION
J.J. CONVERY, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

Clarification of secondary effluents has application in pollution control, direct reuse and as a pretreatment for other tertiary processes such as electrodialysis, reverse osmosis and ion exchange. Alum coagulation, sedimentation and dual media filtration remove essentially all of the suspended solids, phosphorus and BOD associated with the solids from a secondary effluent. The following operating conditions have been found to be optimum: 1. Overflow rate - 700 GPD/FT2. 2. Alum Dose - 300 mg/l. 3. Filter Media a) Anthracite - 18 in. of 1.4 mm b) Sand - 6 in. of 0.45 mm. 4. Filtration Rate - 4 GPM/FT2.

A flocculant aid such as activated silica is necessary to increase the strength of the alum floc and prevent the premature breakthrough of turbidity through the filters. A silica concentration of 3 mg/l as SiO2 is optimum. Filter runs averaged 17 hours for the above operating conditions. Operating costs based on a 10 MGD plant are estimated to be $0.08/1,000 gal.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1366, DISSOLVED INORGANIC REMOVAL--SELECTIVE ION AND ORGANIC REMOVAL BY ION EXCHANGE RESINS
R.A. DOBBS, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

The problems associated with the discharge of nutrients to receiving waters and the incremental build-up of dissolved inorganic salts with each use cycle make it imperative that technology to remove these pollutants be developed and demonstrated. In this area, ion exchange has operational, technical and possibly economic advantages over other processes for demineralization.

In recent years several new types of synthetic resins have been developed, and are commercially available, which are particularly suitable for the removal of selected ions and have the additional capability of absorbing organic matter. Resins, in contrast to activated carbon, can be regenerated in situ by suitable regenerants.

The objective of this study is to develop the use of synthetic ion exchange resins for the selective removal of inorganic ions as well as organic materials. Phase I of the study will include, 1) optimization of flow rates for the exhaustion and regeneration cycles, 2) evaluation of regenerants for imparting selectivity, 3) determination of optimum volume and concentrations of regenerants for imparting 4) performance of the resin after repeated cycles of operation and 5) cost estimates for the process. Phase II will attempt to screen a variety of resins for the above process.

Experimental apparatus consists of multiple 2' glass columns with associated pumps and pressure equipment.

2.1367, REMOVAL OF NITROGEN COMPOUNDS FROM MUNICIPAL WASTEWATER
A.N. MASSE, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

A novel biological treatment process for reducing BOD and nitrogen content of a municipal wastewater is being investigated in a 100 gallons per day pilot plant at the Mill Creek Sewage Works, Cincinnati, Ohio. Primary effluent is treated by the contact stabilization process using abbreviated residence times for

both contact and sludge reaeration. The product from this process is then nitrified aerobically in a separate aeration tank settler combination. The nitrifying sludge is kept in this system. The nitrified effluent flows to an anaerobic, mechanically-agitated denitrifying unit followed by a final settler. The source of organic material to the denitrifying bacteria is sludge from the contact stabilization operation. This sludge has a high BOD/NH3-N ratio, thus decreasing the amount of NH3-N put in the denitrifying section. The sludge from the denitrifying settler is returned to the sludge reaeration tank of the contact stabilization process. Parameters being investigated include residence times and sludge recirculation rates.

2.1368, USE OF GRANULAR ACTIVATED CARBON IN TREATMENT OF WASTE WATERS
A.N. MASSE, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

Granular activated carbon is being investigated as an adsorbent for the non-biodegradable materials in a well-treated municipal secondary effluent. A 300,000 gallons per day plant has been on-stream since May, 1965, at Pomona, California. Four down-flow carbon contractors, connected in series, act as both a filter and an adsorbent bed. When the final product quality exceeds specifications, the first column in the series is regenerated in a 6-hearth furnace and returned to the process as the last column in the series. Parameters being investigated include: a) relationship between contact time and removal of contaminants, b) carbon usage rate, c) effect of regeneration conditions on recovery of carbon capacity and d) attrition losses as a result of carbon handling and regeneration. Side studies on a smaller scale include studies of: a) effect of contact time and mass velocity on adsorption rates and effectiveness, b) nitrogen removal capabilities of carbon columns and c) effect of hot water and steam treatment on regeneration frequency.

Ultraviolet absorption at 2537 Angstrom units of carbon-treated water is being investigated as a rapid control method for the evaluation of carbon column performance. A high correlation exists between UV absorption and organic matter in clarified water. The hydrogen flame detector is being adapted to determine organic matter at levels below 1 mg/l.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1369, POWDERED CARBON TREATMENT OF WASTE-WATER
A.N. MASSE, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

Evaluate a two-stage, counter current pilot plant contacting system for powdered carbon treatment of primary and secondary wastewater effluents. Required amounts of powdered carbon and polymer must be determined as well as the standard design and economic criteria.

With a flow rate of 10 gpm (total residence time in the system of 2.7 hours) secondary effluent to which is added 200 ppm powdered carbon and 1.5 mg/l of organic polyelectrolyte, the total organic carbon removed has averaged 90%. When the influent turbidty can be maintained below 20 J.U., the product turbidity is less than 1 J.U.

When feeding primary effluent at 5 gpm to the system and adding 200 ppm carbon and 3 ppm polyelectrolyte, the total organic carbon reduction has averaged between 85 and 91%. The product turbidity is between 1 and 3 Jackson Units. In all runs on primary effluent, the product quality, as measured by total organic carbon and turbidity, has been better than that produced by the activated sludge process.

Evaluate several powdered carbon regeneration methods in conjunction with the powdered carbon process. Regeneration methods to be tested include: (1) microwave heating, (2) reaction furnace, and (3) fluidized-bed techniques.

2.1370, LIME SLUDGE RECOVERY AND REUSE
M.C. MULBARGER, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

Lime in doses of 200 to 500 mg/l as Ca(OH)2 removes phosphates and suspended matter from secondary effluents. The resultant sludge consists of calcium carbonates and phosphates together with silicate minerals, magnesium hydroxide and organic matter. The lime values may be recovered by recalcining the dried sludge. Although the recovered lime may cost nearly as much as fresh lime, the problem of disposing of large volumes of sludge is solved. Waters differing in hardness and phosphate content have been treated through four cycles and the quantity and quality of the recovered lime has been measured. In soft waters calcium phosphate builds up until it represents over half of the weight of calcined lime without exerting any deleterious effect provided that fresh lime is added to make up the losses. In hard waters calcium carbonate is removed from the water and must be continuously wasted along with low concentrations of calcium phosphate.

2.1371, DISSOLVED REFRACTORY ORGANIC REMOVAL -- CARBON AS AN ADSORBENT AND FILTER MEDIUM
W.A. SCHWARTZ, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

Removal of non-biodegradable organic compounds from wastewater represents an important unit process in the treatment train to obtain a product water useful for a variety of purposes. The single most promising process is adsorption on activated carbon. The objective of this study is to develop a process for removal of organic materials from wastewater by using activated carbon. In addition to adsorption the carbon also lends itself to use as a filter medium in conjunction with other media such as sand.

Primary and secondary treated waste effluents will be subjected to a treatment sequence consisting of coagulation, filtration and activated carbon adsorption. These pretreatments to adsorption will be varied or omitted to provide a variety of influents for the adsorption step. Hydraulic loadings and carbon bed characteristics will constitute additional variables in the study.

Experimental apparatus will consist of 4 inch plastic columns. Performance will be judged on the basis of removal of organic matter and turbidity as well as head-loss measurements. The experimental equipment will be located at the Lebanon experimental facility.

2.1372, A STUDY OF THE KINETICS OF THE ACTIVATED SLUDGE PROCESS
R. SMITH, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

Study the kinetic or time dependent performance of the activated sludge process for the purpose of finding practicable methods for automatic control of the process to minimize the variation of water quality in the effluent stream and to improve the average performance of the process. A mathematical model for the activated sludge process has been developed which computes the process performance as a function of time when the influent stream or the operating decisions or both vary with time. One digital computer program has been completed which simulates the time dependent behavior of the activated sludge process. This computation which is a numerical integration utilizing the Runge- Kutta fourth-order method integrates the Monod differential equations which express the growth of three classes of bacteria: Heterotrophic carbon users, Nitrosomonas which converts ammonia to nitrite, and Nitrobacter which converts nitrite to nitrate.

The aerator is sub-divided into ten sub-volumes, any number of which can be used to simulate mixing, and a sludge storage tank is provided in the sludge return line. A surge tank, in which

no biological activity is assumed, is also provided upstream of the aerator. Sinusoidally varying flow and BOD concentration are applied to this system and the concentration of three classes of microorganisms and three substrates as well as flow are computed as a function of time at each of seventeen stations. Various control schemes involving pumping of sludge from the sludge storage tank to minimize the effect of the varying load on the plant or the use of the surge tank to smooth out the flow have been studied.

The ultimate goal of the time dependent model is to study methods for control of the activated sludge process to give optimum performance when the flow and BOD concentration entering the plant varies throughout the day.

2.1374, REMOVAL OF TRACE METALS FROM WATER BY ION FLOTATION
A.J. RUBIN, Ohio State University, Water Resources Center, *Columbus, Ohio* 43210

Contamination of domestic and industrial water supplied by trace metals is of increasing concern. The possible economic damage and potential health hazards of certain trace metals coupled with the difficulty in their removal requires a new approach in treatment process selection and design. Ion flotation, a new low gas flow -rate foam separation technique, offers promise as an effective unit process for the selective removal of such trace metals.

The general objectives of this research are to (1) investigate the variables affecting metal ion removal by ion flotation, and (2) establish design criteria for an ion flotation process. For the first year of the proposed research, the specific objectives are to study the kinetics and variables affecting the removal of lead (II) in batch ion flotation systems. Other cations will be investigated during the second year, and as time permits during the first year after completion of the lead (II) studies. These variables, which affect the rate and/or degree of removal, include the metal ion and collector surfactant concentrations, gas flow-rate , pH, and ionic strength. Interactions between variables will also be determined.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1375, COAGULATION OF CLAYS WITH HYDROLYZING METALS
A.J. RUBIN, Ohio State University, School of Engineering, *Columbus, Ohio* 43212

One of the most widely used chemical processes in both water and wastewater treatment is that of coagulation. Clarification of turbid waters by this process is usually accomplished by addition of iron or aluminum sulfate and pH control. Provisions for rapid mixing of the chemicals, slow mixing for particle growth, and settling (or flotation) of the flocs are required. Although there is a vast literature on coagulation, very little impact has been made on practice. Only recently has coagulation research been sufficiently systematic and quantitative to elucidate some of the mechanisms underlying the process. There is a need both for further sound research on the factors controlling the coagulation process and an evaluation of research findings toward engineering practice. It is the purpose of the proposed research to investigate, in a systematic program, the basic mechanisms controlling the coagulation of clays and other hydrophobic sols. The significance of several chemical parameters of importance in wastes and natural waters will be examined. Evidence for the precipitation model of coagulation will be evaluated and the findings will be interpreted and related to practice whenever possible.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1376, RELATIONSHIP OF ACTIVATED SLUDGE BULKING TO ORGANIC LOADING, OXYGEN AVAILABILITY, AND HYDRAULIC CHARACTERISTICS OF THE AERATION TANK
K.S. SHUMATE, Ohio State University, Water Resources Center, *Columbus, Ohio* 43210

The specific objectives of this research are to investigate the interrelationships between oxygen availability, organic loading, agitation intensity, and mixed liquor age distribution as factors contributing to sludge bulking in the activated sludge process. A physical simulation of the complete mix reactor-in-series model will be used to provide controlled variation of mixed liquor age distribution. Agitation in the aeration tanks will be controlled by the combined use of diffused air and mechanical stirring. Diffusor air flow rate will be varied as required, and the mechanical stirrers will be adjusted to control the total power input per unit volume, which will be used as the parameter of agitation intensity.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1377, PRECIPITATION OF PHOSPHATES FROM WATER WITH FERROUS SALTS
K. SVANKS, Ohio State University, School of Engineering, *Columbus, Ohio* 43212

The objectives of this study are to determine: 1) The mechanism of the reaction and optimal conditions under which ferrous hydroxide (applied directly or indirectly in form of ferrous sulfate) may be used to remove phosphates from water. 2) Methods of removing the insoluble phosphates and polyphosphates formed in the reaction, with particular emphasis on flotation processes. 3) The effectiveness of insoluble ferrous salts with or without flocculants to reduce the BOD and total nitrogen and the possible interference of these and other substances to the removal of phosphates.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1378, AUTOMATED SYSTEM FOR WATER POLLUTION CONTROL FROM AN ANIMAL PRODUCTION UNIT
E.P. TAIGANIDES, Ohio State University, School of Agriculture, *Columbus, Ohio* 43210

To make the total animal production unit prove effective in meeting our ever-increasing demands for more and better quality animal products, there exists a need to develop a manure management technology which will meet both the public demand for control of environmental pollution (water pollution and aesthetic nuisance) and the producer's demand for the mechanization of the manure handling operations.

The specific objectives of the project are: a. to demonstrate to animal producers the type of waste treatment unit operations which could be used to process wastes from animal production units, b. to demonstrate a system of automated handling of animal wastes, c. to demonstrate an animal waste treatment system which would not create a public nuisance and whose effluent could be of such quality that it could not contribute to water pollution.

The wastes from a 500-pig confinement unit will be flushed into a settling tank. The supernatant of the tank will be processed by aeration in an oxidation ditch, clarified, deodorized and recirculated through the animal building as flushing water. The solids settled out of the settling tank will be composted with a liquid composter and afterwards disposed by field spreading.

The field work will be carried out at the Botkins Grain and Feed Company Research Farm in Botkins, Ohio, some 90 miles away from Columbus, Ohio.

The project would be initiated January 1, 1970 and terminated June 30, 1971.

2.1379, STUDY OF UTILIZATION AND DISPOSAL OF LIME SLUDGES CONTAINING PHOSPHATES
R.E. OPFERKUCH, Monsanto Research Corporation, *Dayton, Ohio* 45407

The technical and economic feasibiliry of utilizing the sludges obtained from the lime treatment of wastewater to remove phosphates will be determined. Economic, market, and engineering studies will be made on each potential large volume (sulfate fertilizers, wet process phosphoric acid, and phosphated fertilizers) outlet for phosphate sludge. Samples of recovered lime from a number of installations where classification of waste waters is carried out will be evaluated.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

2.1380, ELECTRODIALYSIS TREATMENT OF SECONDARY EFFLUENT
C.A. BRUNNER, U.S. Dept. of the Interior, Federal Water Quality Admin., *Lebanon, Ohio*

Electrodialysis is being pilot tested to determine the feasibility of the method for partially demineralizing municipal wastewater. The partial demineralization is necessary for removal of the increment of inorganic material added during use and becomes especially important when multiple reuse of the water is considered.

The pilot system consists of a 50-gpm electrodialysis stack. Feed to the stack is clarified and granular-activated-carbon treated municipal secondary effluent. The design value of the fraction of mineral removal is 40 percent. Concentrated waste rate is maintained at less than 10 percent of the product rate. During operation the degree of demineralization is monitored frequently by conductivity measurements of feed and product. Analyses of principal ions are obtained occasionally.

An operating problem that has been encountered is anion membrane fouling. The result of fouling is a decline in demineralization. Since the problem first arose, much of the experimental work has been aimed at overcoming it. Although fouling has been reduced by improved clarification, it has not been completely eliminated. The fouling materials can be removed by allowing the equipment to remain idle for several days.

In spite of the fouling problem, electrodialysis is considered to be technically feasible. Longer study is required to determine accurately the economic feasibility, but present estimates indicate the process is practical.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1381, SINGLE STAGE LIME TREATMENT OF WASTEWATER
C.A. BRUNNER, U.S. Dept. of the Interior, Federal Water Quality Admin., *Lebanon, Ohio*

In certain envisioned reuses of wastewater, it is essential to remove suspended material. Chemical clarification with lime is one possible method of removal. In this study, lime clarification is being used to treat municipal secondary effluent prior to granular activated carbon treatment and demineralizatio by electrodialysis.

Secondary effluent is supplied to a circular up-flow clarifier at a rate of 75 gal. per min. Lime slurry and secondary effluent are mixed in a rapid mix zone where precipitation occurs. The mixture passes through a sludge blanket and finally into the sedimentation zone. The effluent from the clarifier is further polished with two dual media filters (anthrafilt and sand). The total organic carbon, suspended solids or turbidity, alkalinity, hardness, and phosphate concentration of feed and product water are monitored. The most important operating variable is the clarifier pH. Studies are being made over the pH range 9 to 10.5. Limited study has been made of flocculant aids.

Results indicate that good clarification can be obtained at pH values from 9 to 10.5 without a flocculant aid. Phosphate removal is also good over that pH range. Significant calcium and alkalinity removals occur at pH of 9.5.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1382, THE CHARACTERISTICS AND POLLUTIONAL PROBLEMS OF IRRIGATION RETURN FLOWS
J.P. LAW, U.S. Dept. of the Interior, Federal Water Quality Admin., *Ada, Oklahoma* 74820

Preparation of a comprehensive report that will reflect the status of present knowledge regarding the pollutional problems associated with irrigation waste waters and their effects upon water quality of surface streams and groundwater resources in the United States.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1383, DEMONSTRATING THE EFFECT OF NUTRIENTS IN OXIDATION POND RECEIVING STREAMS
G.W. REID, Univ. of Oklahoma, Research Institute, *Norman, Oklahoma* 73069

Studies of receiving streams or drainages of operating waste stabilization ponds will be conducted to evaluate critically the fate of nitrogen and phosphorous, bacteria, algae and BOD of effluents subsequent to treatment by lagooning.

2.1384, MICROBIOLOGICAL REMOVAL OF IRON FROM MINE DRAINAGE WATERS
R.C. ALLRED, Continental Oil Company, *Ponca City, Oklahoma* 74602

The removal of iron from mine drainage waters using a two-step microbiological process will be investigated both in the laboratory and in the field. It is proposed to change iron from ferrous to ferric state using iron-oxidizing bacteria, followed by precipitation of a ferric sulfide using sulfate-reducing bacteria.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1385, OPERATIONAL STABILITY OF THE EXTENDED AERATION PROCESS
A.F. GAUDY, Okla. St. Univ., School of Engineering, *Stillwater, Oklahoma* 74074

Preliminary investigations on the stability of operations of the extended aeration process (no sludge wasting) over a period of nearly one year indicated that while the unit activity of the sludge dropped off during the operational period, the total waste purification capacity of the process remained extremely high. The proposed laboratory investigations are directed toward determination of the useful life of an extended aeration process and determination of the biochemical causation for breakdown, if such systems do eventually break down. It is also intended to determine the degree of stability of the process under changing environmental conditions and whether there is any useful parameter (s) which can be used to predict either impending upsets or continued efficient operation.

Laboratory pilot plants will be operated and all sludge except a small measured amount (plus or minus 2%) for analyses and batch experimentation will be returned to the aerator. Substrate removal efficiency, biological solids production, and sludge composition will be determined, and small sludge samples will be taken for measurement of unit activity with respect to oxygen uptake and substrate removal. Analysis of the data should permit useful conclusions concerning the utility of the process and possible ways to extend its use to a greater variety of waste water applications.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1386, KINETICS AND MECHANISMS IN ACTIVATED SLUDGE PROCESSES
A.F. GAUDY, Okla. St. Univ., School of Civil Engineering, *Stillwater, Oklahoma* 74074

The broad objective of the proposed research is the attainment of a more sound understanding of the basic chemical, physical, and biological factors underlying the kinetics and mechanisms involved in growth and substrate utilization in

heterogenous populations with particular reference to waste water purifcation in continuous and discontinuous activated sludge processes.

Since its initiation in 1962, the research has progressed toward accomplishment of this goal through the conduct of massive, long-term experiments under closely controlled conditions using a variety of steady, well-defined chemical and physical environments. A large number of analytical parameters have been determined and subjected to statistical analysis. Through continuation of this approach, the completion of the work should allow determination of the mechanistic and kinetic parameters which are of significance in formulations of predictive value for design and operation of activated sludge processes. During this renewal period all results obtained on this project will be integrated and consolidated with results of related studies conducted on the biological response to a changing environment (WP-00075) and with studies conducted on genetic and enzymic mechanisms of metabolic control applicable to heterogenous populations (WP-00786).

2.1387, ADSORPTION OF VIRUS-SIZED PARTICLES IN POROUS MEDIA
R.W. FILMER, Oregon State University, School of Engineering, *Corvallis, Oregon* 97331

The fate of water-borne viral pathogens is a question of vital concern when untreated or partially treated waste water is used to replenish underground sources of supply. Little information is available concerning the mechanism by which ultra-small particles such as viruses are removed from suspension by soil materials. There is no data available from which accurate predictions can be made as to how far such contaminants will traval in a given water-bearing strata. Under this research program the removal process will be studied in detail and an attempt made to develop predictive relationships.

SUPPORTED BY U.S. National Science Foundation

2.1388, CHARACTERIZATION OF FOOD PROCESSING WASTEWATERS
M.R. SODERQUIST, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

It is proposed that a portable laboratory be sequentially located at various food processing centers during each of the next three summers for the purpose of conducting comprehensive (24 hour/day) sampling and on-site wastewater quality analyses of the effluents. Data will be obtained for the processing of each of the many commodities produced in the Pacific Northwest, including fruits, vegetables, seafoods, meats, poultry and dairy products. Parameters to be measured would vary with the nature of the waste, but would normally include flow, total, dissolved- and volatile-solids, five-day biochemical oxygen demand, ultimate biochemical oxygen demand, chemical oxygen demand, nitrate, ammonia, organic nitrogen, orthophosphate, total phosphate, treatability, microbiological analyses. Where warranted, chloride, sulfide, and other unconventional analyses necessary for the complete characterization of the waste under study. Results would be related to production (i.e., BOD sub 5 would be expressed not only as a concentration, mg/l, but also as lbs. BOD sub 5 /ton of product processed) and the influence of plant size (production volume) on efficiency of water use would be investigated.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1389, THERMAL WATER DEMONSTRATION PROJECT
B. PRICE, Eugene Water & Electric Board, *Eugene, Oregon* 97401

The grant will be used to support a pilot demonstration program to show the possibilities for the multiple use of water warmed by industrial plants. The demonstration will be based on the state of the art as it existed when the project began in March, 1969. Results of new or recent research will be correlated into the program. Results of the project could be immediately applied into the National Water Resources program and the treatment of thermal-polluted water by the Federal Water Pollution Control Administration as well as other Government agencies and industry.

The assesment and evaluation of the proposed demonstration program will show economic benefits not only to agriculture but to fisheries, recreation, and related water- and land-use projects as they respond to the total utilization concept and its demonstration harmonization.

Of primary importance will be the demonstration that thermal water from nuclear-powered electrical generating plants, if properly managed, will not become a thermal pollutant.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1390, WASTE WATER PURIFICATION
F.J. MICALE, Lehigh University, Graduate School, *Bethlehem, Pennsylvania* 18015

A fundamental approach to the problem of waste water treatment is a determination of the mechanism whereby soluble and solid impurities are more efficiently removed from their aqueous environment. Although the problem is complicated by the complex nature of waste sludges, especially activated sludges, the ultimate driving force for any of the accepted water treatment operations occurs at the interface between various phases involved in a particular operation. The objective of this research program, simply stated, is to relate the interfacial properties to the dewatering characteristics of a sludge system.

Experimental evidence has shown that three incinerator ashes, and a Beckjord fly ash, exhibit varying degrees of effect on the sedimentation rate of activated sludges. In general, the addition of these ashes drastically increases the sedimentation rate. The objective of this program is to investigate the mechanism which leads to an increase in sedimentation rate. The surface properties of a number of ash samples will be studied with respect to particle size, specific surface area, composition, solution adsorption to various surfactants, and the concentration and effect of water soluble ions present on the ash surface. A number of model surfaces, e.g., silica, and carbon black, will also be investigated in order to determine their effect on the sedimentation rate of activated sludges as a function of ionic concentration.

2.1391, NEUTRALIZATION AND PRECOAT FILTRATION OF CONCENTRATION SLUDGES FROM MINE WATER
D.R. MANEVAL, State Dept. of Mines & Min., *Harrisburg, Pennsylvania* 17120

The project is directed at providing a cost-effectiveness evaluation of various neutralization processes in the treatment of acid mine drainage. Sludge disposal problems will be studied with emphasis on precoat filtration. Field tests will be accomplished on four abandoned mines in the Western Pennsylvania area.

Johns-Manville Company will perform the work. It is hoped that this method will provide significant information on economic feasibility of reducing acid mine drainage by neutralization.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1392, ABATEMENT OF MINE DRAINAGE POLLUTION BY REVERSE OSMOSIS
D.R. MANEVAL, State Dept. of Mines & Min., *Harrisburg, Pennsylvania* 17120

Previous work has shown that high ferrous AMD causes fouling of membranes. The proposed work is intended to minimize this, as well as other problems by conducting the following: 1. Laboratory studies, using synthetic AMD, designed to determine exact causes of and cures for iron fouling. 2. Optimization of alternate flow schemes. 3. Detailed cost analysis. 4. Sampling of mines to determine feasibility of obtaining AMD with no dissolved oxygen. 5. Field testing to verify lab results.

The laboratory work will be conducted at Rex Chainbelt, Inc., West Milwaukee, Wisconsin. The field work at possible sites in Pennsylvania.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1393, RECOVERY OF IRON IN A MORE DENSE FORM FROM COAL MINE DRAINAGE
D.R. MANEVAL, Bituminous Coal Research Inc., *Monroeville, Pennsylvania* 51146

The overall research program will be conducted in three phases. This project covers the first phase, including development of a conceptual process for the removal of iron sludge by means of a magnetic precipitate. Operation will be on a bench-scale, with test work to lead to the development of a continuous flow process for the treatment of specific types of mine drainage.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1394, DEVELOPMENT AND OPTIMIZATION OF THE LIMESTONE TREATMENT OF MINE DRAINAGE
R.K. YOUNG, Bituminous Coal Research Inc., *Monroeville, Pennsylvania* 51146

Initial achievement of this project, along with further laboratory studies, lead logically to the development of the process by designing, constructing and operating of research units in the field to obtain process design and engineering data for a detailed evaluation and cost estimate of the process projected to full industrial scale operation.

The laboratory studies will include: The evaluation of limestones by describing their physical and chemical properties and development of neutralization curves; and proof of such evaluation by conducting batch tests, continuous flow tests with determinations of sludge properties.

The design of the Field Research Unit will include; selection of variables, including site, the number of discharges and limestones, flow rates and the type of field unit; treatment conditions and effluent standards; engineering design; procurement; erection and installation requirements; and a summary report.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1395, TREATMENT OF WATERCRAFT WASTES
J.C. WHITE, General Electric Company, *Philadelphia, Pennsylvania* 19123

The design and development of a watercraft waste treatment system to be demonstrated functionally on a vessel with a crew of 40 to 50 men. The treatment utlizes an electrocoagulation cell to form a settleable floc from the sanitary and culinary sewage. Separation of this floc permits discharge of a chlorinated non-contaminated supernatant. The accumulated sludge will be collected and stored for disposal as determined by the initial project scope.

The design and functional shipboard demonstration of the system form two discrete phases of the project. In the initial phase of the system consisting of a pump-storage-grinder, electrocoagulation cell, settling tank, and chlorinator will be demonstrated functionally in the laboratory. Performance in static and simulated sea state conditions will be assessed.

Concurrently with the laboratory testing, a vessel will be selected for the second phase of the contract - the demonstration under actual conditions. Preparation for installation on a vessel entails a waste characterization of the selected vessel, and a suitable seaworthy design of the waste treatment system.

2.1396, CHEMICAL TREATMENT OF ACID MINE DRAINAGE
UNKNOWN, Bituminous Coal Research Inc., *Pittsburgh, Pennsylvania* 15213

No summary has been provided to the Science Information Exchange.

SUPPORTED BY Appalachian Regional Commission

2.1397, TREATMENT OF ACID MINE DRAINAGE-SULFUR AND IRON RECOVERY
J.A. KARNAVAS, Black Sivalls & Bryson Inc., *Pittsburgh, Pennsylvania* 15238

Obtain bench-scale laboratory data to determine the technical and economic feasibility of the BS&B process for acid mine water (AMW) treatment.

In this process, AMW is distilled with energy generated from inexpensive high-sulfur coal. The coal is combusted in a liquid iron bath to recover its sulfur content in a slag, from which elemental sulfur is recovered via a modified Claus process.

Laboratory studies are being conducted by Chemical Service Engineers, Inc., Pittsburgh, Pennsylvania, to provide data on the fluidity of slags, the partition of sulfur between iron and slag, the kinetics of sulfur recovery from slag, and the neutralization of AMW with slag.

The evaluation of the process will be based on the laboratory results, other available data, and a computer simulation of the process.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1398, ACID MINE DRAINAGE PILOT PLANT EVALUATION
UNKNOWN, Carnegie Mellon University, Mellon Institute, *Pittsburgh, Pennsylvania* 15213

No summary has been provided to the Science Information Exchange.

SUPPORTED BY Appalachian Regional Commission

2.1399, STUDY OF THE USE OF INERT GASES TO ELIMINATE ACID POLLUTION FROM ABANDONED DEEP MINES
H.C. BRAMER, N U S Corporation, *Pittsburgh, Pennsylvania* 15205

This is the continuation of a project initiated during the 67 fiscal year. The initial phase studied the air flow required to seal two abandoned deep mines in Stewart Township, Fayette County, Pennsylvania. These mines had several major air leaks both through the overburden and barrier of the adjacent strip mine. These leaks prevented any significant build-up of pressure within the mine.

This continuation of the project will consist of an evaluation of the state-of-the-art of existing technology to locate points of air leakage from the mine; installation of seals in mine openings presently covered by backfilling operations of the strip mine; installation of larger air blowing equipment; and continuation of the original study work to pressurize the mine.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1400, A CONCEPTUAL STUDY OF THE DISTRICT OF COLUMBIA BIOLOGICAL TREATMENT PILOT PLANT
C. WOOD, Swindell Dressler Company, *Pittsburgh, Pennsylvania*

To perform a study to develop the concept of the District of Columbia Biological Treatment Pilot Plant in accordance with the requirements set forth herein: I. Study Criteria: A. Evaluate the process layout and hydraulic requirements of the two train (100,000 gpd per train) biological treatment pilot plant as described in the attached specification for installation at the District of Columbia Water Pollution Control Plant. B. Develop a sludge disposal system for the above pilot plant which includes: 1. Sludge dewatering systems. a. vacuum filtration. b. centrifugation. c. experimental dewatering. 2. Sludge incineration. C. Prepare functional process layout for two larger pilot plants based on the design criteria and flexibility in above D.C. pilot plant and including disposal facilities for plant sized with: 1. Two nominal 250,000 gal per day treatment trains. 2. Two nominal 500,000 gal per day treatment trains. D. Furnish a cost estimate for the (100,000 gpd/train) pilot plant in A above.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1401, ENVIRONMENTAL CONTROL RESEARCH CONTROL TECHNIQUES, FIELD TESTING, AND EVALUATION
N.N. MOEBS, U.S. Dept. of the Interior, Bureau of Mines, *Pittsburgh, Pennsylvania* 15213

The immediate objective of the Water Control program is to continue collecting and analyzing water effluents and air samples; obtain geologic, hydrologic, and mine data; and develop plans cooperatively with engineers of involved coal operations to reduce the quantity and improve adequately the quality of the water discharged from active mines.

Cooperative agreements with four coal companies are in effect, with encouraging prospects to seal and inundate 30 to 70 percent of the area of one mine to eliminate present treatment within 1 or 2 years after the mine is worked out; and to pipe a low acidity quantity of water generated in the active area of another mine (approximately one-half of the total discharged daily from the below drainage mine) to the main pump sump rather than permit it to flow first into the highly acid water in the main pool located within an old mined out area and, thereby, reduce the cost of treatment.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

2.1402, IMPROVED EXTRACTION SYSTEM - WATER CONTROL - CONTROL TECHNIQUES, FIELD TESTING AND EVALUATION
N.N. MOEBS, U.S. Dept. of the Interior, Bureau of Mines, *Pittsburgh, Pennsylvania* 15213

The immediate objective of the water control program is to continue collecting and analyzing water effluents and air samples; obtain geologic, hydrologic, and mine data; and develop plans cooperatively with engineers of involved coal operations to reduce the quantity and improve adequately the quality of the water discharged from active mines. Monitoring the flow and quality of effluents from, and of air in abondoned sealed underground mines.

Cooperative agreements with three coal companies are in effect, with encouraging propects to seal and inundate 30 to 70 percent of the area of one mine to eliminate the need for treatment within 1 or 2 years after the mine had been worked out: and to pipe a low acidity quantity of water generated in the active area of another mine after exhaustion and sealing (approximately one-third of the total discharged daily from the below drainage mine) to the main pump sump rather than permit it to flow first into the highly acid water in the main pool located within an old mined out area and, thereby, reduce the cost of treatment.

Also, installation of a continuously recording oxygen meter at a borehole in the first mine mentioned above has shown strikingly the degree of 'breathing' occurring at that mine after sealing.

At the third active mine, water samples and rock and coal cores are being analyzed to evaluate the potential for water pollution.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

2.1403, DEVELOPMENT OF CRITERIA FOR REGIONALIZATION OF WATER WASTES MANAGEMENT SYSTEMS
O.H. SAUERLENDER, Penn. State University, Inst. for Res. on Land & Water, *University Park, Pennsylvania* 16802

The proposed research project will study a part of the Middle Susquehanna river basin to analyze the existing structure of water management and sewage disposal systems. The purpose is to discover the relationship of social factors and institutional constraints leading to success and/or failure of communities securing the economies of scale that would result from the consolidation of smaller plants into single larger units.

Field investigation will gather information on the adequacy of existing systems to meet existing and projected demands for water and waste disposal. Costs of maintaining existing systems or for improving systems to satisfy standards of water quality established by the state will be computed and compared with costs of alternative water management systems including varying degrees of regional control.

The socio-economic structure of the entire region will be analyzed for developing criteria to determine the optimum regionalization regarding the management of water resources and waste disposal.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1404, EFFECTS OF IRRIGATION OF MUNICIPAL SEWAGE EFFLUENT ON SPOILS BANKS
W.E. SOPPER, Penn. State University, Inst. for Res. on Land & Water, *University Park, Pennsylvania* 16802

The purpose of the project is to investigate the feasibility of ameliorating adverse strip mine spoil bank sites through irrigation with municipal sewage effluent. Benefits derived from such a method, if feasible, would be twofold (1) alleviation of stream pollution as a result of diversion of the effluent load from streams to land areas and (2) restoration of these disturbed land areas to useful productivity. The specific objectives are: (1) to determine the degree of chemical renovation of municipal sewage effluent and sludge by spoils bank material, (2) to determine the extent of site amelioration as a result of irrigation of sewage effluent and mixtures of effluent and digested sludge on spoils banks material and (3) to determine the effectiveness of various proportions of sewage effluent and sludge and various amounts of the mixture on the revegetation of the spoils material.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1405, MICROBIOLOGICAL CHARACTERIZATION OF ACTIVATED SLUDGE IN A WASTEWATER TREATMENT PLANT CHEMICALLY MODIFIED FOR PHOSPHORUS REMOVAL
R.F. UNZ, Penn. State University, Inst. for Res. on Land & Water, *University Park, Pennsylvania* 16802

Full scale combined chemical-biological wastewater treatment for simultaneous removal of organic matters and phosphorous is in the pioneer stage. There is little evidence to show that the biological solids are not qualitatively and/or quantitatively altered in microbial composition as a result of chemical treatment. There is no information on the bacteriological quality of the effluent from the combined treatment systems.

The objectives of this study are: 1. To obtain basic information on the microbial composition of activated sludges before and following chemical treatment of wastewaters for phosphorous removal. 2. Assuming variations in wastewater treatment efficiency result during chemical treatment, it is the intent to determine if the changes in treatment efficiency parallel changes in microbial composition of the activated sludge. 3. To consider reasons for microbial diversity in activated sludges if such seems to be related to chemical treatment of the wastewaters. 4. To supplement the data to be collected by personnel connected with the engineering aspects of phosphorous removal project being conducted at this university's wastewater treatment plant and to contribute toward the final evaluation of that project as well as general design and operation of combined chemical-biological wastewater treatment schemes.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1406, BIOLOGICAL TREATMENT PILOT PLANT AND SLUDGE DISPOSAL FACILITY
W.E. HOOVER, Roy F. Weston Incorporated, *West Chester, Pennsylvania* 19380

The scope of work of this contract requires the designer to: A. Complete a detailed design of a dual stream 100,000 gpd per train biological treatment pilot plant as described in the attached specifications. B. Design a sludge disposal facility for the above pilot plant which includes: 1. Sludge dewatering systems which include: a. vacuum filtration b. centrifugation c. one other dewatering method to be determined. 2. Sludge incineration. C. Provide cost estimates for construction of scaled up plants of the above

basic design with the following capacities: 1. One dual stream plant of 250,000 gal per day capacity per train 2. One dual stream plant of 500,000 gal per day capacity per train.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1407, A CONCEPTUAL STUDY OF THE DISTRICT OF COLUMBIA BIOLOGICAL TREATMENT PILOT PLANT
V.T. STACK, Roy F. Weston Incorporated, *West Chester, Pennsylvania* 19380

To perform a study to develop the concept of the District of Columbia Biological Treatment Plant in accordance with the requirements set forth herein: I. Study Criteria A. Evaluate the process layout and hydraulic requirements of the two train (100,000 gpd per train) biological treatment pilot plant as described in the attached specification for installation at the District of Columbia Water Pollution Control Plant. B. Develop a sludge disposal system for the above pilot plant which includes: 1. Sludge dewatering systems a. vacuum filtration b. centrifugation c. experimental dewatering 2. Sludge incineration C. Prepare functional process layout for two larger pilot plants based on the design criteria and flexibility in above D. C. pilot plant and including sludge disposal facilities for plant sized with: 1. Two nominal 250,000 gal per day treatment trains 2. Two nominal 500,000 gal per day treatment trains D. Furnish a cost estimate for the (100,000 gpd/train) pilot plant in A above.

2.1408, TOCKS ISLAND REGION ENVIRONMENTAL STUDY (TIRES)
R.F. WESTON, Roy F. Weston Incorporated, *West Chester, Pennsylvania* 19380

The Tocks Island Region Environmental Study deals with regional consideration of waste disposal and water supply needs for the next 50 years, and maintenance of the existing high quality environment in the 1000 square mile interstate area surrounding the Tocks Island Reservoir and the Delaware Water Gap National Recreation Area. The objective of the study is to develop a master plan for water supply and waste disposal in the three state, six county area expected to undergo rapid development pressures as a result of the reservoir and park developments. Major emphasis has been devoted to the study and feasibility of alternative regional and subregional sewerage schemes for the region. The study is being carried out in cooperation with all concerned local, state, and federal agencies in the region.

SUPPORTED BY Delaware River Basin Comm. - Washington

2.1409, DETERMINATION OF BIODEGRADATION RATES IN SOME POLLUTED TROPICAL WATERS AND IN SOME TYPES OF LIQUID WASTES COMMON IN PUERTO RICO
L.A. DELVALLE, Univ. of Puerto Rico, Water Resources Research Inst., *Mayaguez, Puerto Rico*

As such, there is no information available in regards to the effect of salt concentrations on the biodegradation rates of wastes and of the concentration of the wastes themselves in tropical zones.

This study is to determine the biodegradation rates on some types of wastes common in the tropical waters of Puerto Rico, with due regard to the effect of concentration and salinity, to evaluate different methods of analysis already available in pertinent literature.

To achieve this, an adequate number of samples of wastewater will be analyzed, both in their natural state and diluted in river and sea- water. Their biodegradation rates will be determined using the most adequate B.O.D., COD and/or T.O.C. techniques.

The result of the study will attempt to fulfil the general lack of information on the biodegradation rates of some common tropical waste- water not encountered in many parts of the nation, but in Puerto Rico. Moreover, it should be of valuable help to agencies dealing with water pollution control and the design of waste treatment works.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1410, CONTROL OF GEOTRICHUM CANDIDUM IN BIOLOGICAL WASTE TREATMENT
C.P. POON, Univ. of Rhode Island, School of Engineering, *Kingston, Rhode Island* 02881

The proposed research plan involves laboratory and field investigations directed at the determination of the control of filamentous Geotrichum candidum fungus in biological waste treatment.

The first four phases of this work will investigate factors giving rise to G. candidum overgrowth which causes bulking of sludge. Warburg respirometric technique and prototype laboratory aerators will be used in the work. The last phase of this work involves investigations of methods of control, using coagulation and fungicides, to eliminate the fungus after the treatment unit has been infested with this filamentous organism. Prototype laboratory study and field tests will be conducted for this phase of the work.

The five phases of this work include: 1. Metal toxicity --- silver, copper, zinc and chromium 2. Metal stimulation --- zinc, copper, cobalt, zinc and iron combined 3. Interactions of ions --- Antagonistic and synergistic actions of zinc, copper and cobalt with magnesium, calcium carbonate, selenite, tellurite and sulfhydryl compounds 4. Photosensitization --- photochemical reaction of bituminous material. All substances aforementioned may selectively favor the growth of G. candidum over the zoogleal bacteria in sludge to cause bulking. 5. Control -- coagulants, sludge ash and fungicides.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1411, CHEMICAL AND PHYSICAL FACTORS IN THE FLOCCULATION OF METAL PROCESSING WASTES WITH POLYELECTROLYTES
D.L. SUSSMAN, Univ. of Rhode Island, School of Engineering, *Kingston, Rhode Island* 02881

The proposed research plan involves the study of the factors involved in the flocculation of metal treatment wastes with polyelectrolytes. These factors are the effects of multivalent ions, pH, ionic strength, complex formation, the type of colloids present, organic matter and the rate of sedimentation.

The laboratory investigations will involve the measurement of the destabilization and flocculation of the colloidal particles by use of a light scattering photometer. Particle size measurements will be determined by the refiltration technique. The theoretical basis of this measurement is the Kozeny-Carmen equation for flow through a porous media.

These measurements will be made on laboratory prepared wastes and on samples of wastes taken from metal finishing operations in the Rhode Island and Southeastern New England area.

The objective of this project will be to determine the optimum conditions for improving the treatment of metal finishing wastes by polyelectrolyte addition.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1412, GROUNDWATER FLOW IN PARTIALLY SATURATED SOILS
M.C. WANG, Univ. of Rhode Island, School of Engineering, *Kingston, Rhode Island* 02881

The proposed research project involves laboratory and field investigations of non-steadystate unsaturated groundwater flow from disposal fields. The long-range objective of the study is to determine the minimum spacing required between a water supply and a sewage disposal field so that contamination of the water supply will be minimized.

Laboratory investigations would involve the following steps: 1. Development of a theoretical approach to the non-steadystate unsaturated seepage flow. 2. Determination of the hydraulic conductivity of unsaturated soils. 3. Verification of the theoretical solution with model study.

A tile drainage field near the college sewage treatment plant with field observation wells at varying distances away is planned to verify the results established in the laboratory.

Results of the study would be established in tabular or graphical form for various hydraulic conditions, soil types and fluid supplies.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1413, GEIGY CHEMICAL WASTE TREATMENT FACILITY

R.F. CURRAN, Geigy Chemical Corporation, *Providence, Rhode Island* 02905

The proposed project is for the full scale (1.4 MGD) treatment of chemical wastes from a multiple organic products plant. The system for treatment is to have as its major component a multi-stage plastic trickling filter system and is to be automated to produce controllable process resulting in a consistent quality effluent suitable for discharge to receiving waters.

Project Objectives Include: 1. Demonstration of the feasibility of a multi-stage plastic media trickling filter process for wastewaters from a multiple organic chemicals plant. 2) Develop and demonstrate technical feasibility of total process control by automated systems for the process. 3. Evaluate the performance of a specific design of plastic media. 4) Demonstrate the stage-wise acclimation of micro- organisms as a factor in attaining extra high loading per unit of trickling filter packing. 5) Obtain performance data on an additional treatment operation, such as activated carbon adsorption, for further effluent quality improvement.

Construction of the facility was commenced in April 1970. Operational start-up is anticipated in April 1971 and it is expected that this research project will be completed by September 1972.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

2.1414, ZEOLITE REMOVAL OF 137-CS FROM LIQUID WASTE

R.H. HAWKINS, U.S. Atomic Energy Commission, Savannah River Plant & Labs., *Aiken, South Carolina* 29801

The objective of this study is to improve the operation and reduce the cost of removing 137 Cs from Savannah River Plant liquid waste. Pluggage has been a frequent problem with zeolite columns now in routine operation. Also, regeneration is not attempted. Causes of pluggage have been narrowed to suspended solids in feed and a precipitate due to reaction between feed and zeolite. A 6' long column of zeolite serving as a granular, backwashable prefilter has significantly improved performance of laboratory cesium removal zeolite columns.

SUPPORTED BY U.S. Atomic Energy Commission

2.1415, ION EXCHANGE MEMBRANE STUDIES

R.M. WALLACE, U.S. Atomic Energy Commission, Savannah River Plant & Labs., *Aiken, South Carolina* 29801

The objective of this program is to investigate the application of ion exchange membranes (Donnan membrane equilibria) to the concentration of radionuclides from dilute aqueous waste streams.

Both flat and tubular membranes are being studied. Potential of the technique for scale-up to flow rates of tens of gallons per minute is being explored. Costing studies are planned to determine if membrane concentration is competitive with evaporation and conventional ion exchange.

Studies with dilute aqueous waste indicate super 137 Cs concentration of 1000 with 50-fold volume reduction may be feasible. Small scale units were designed for tests with flat membranes, a commerical source of tubular ion exchange membranes was located and a tubular dialyzer was purchased for evaluation.

SUPPORTED BY U.S. Atomic Energy Commission

2.1416, STUDY OF COSTS OF TREATING TEXTILE WASTES IN MUNICIPAL AND INDUSTRIAL SEWAGE PLANTS

J.M. STEPP, Clemson University, Water Resources Research Inst., *Clemson, South Carolina* 29631

The textile industry, which is concentrated and still growing in the Carolinas and Georgia, is a major user and polluter of water while at the same time requiring high-quality water for dyeing and finishing operations. The liquid wastes from such operations are strong, complicated, variable, and difficult to remove from wastewater. The public interest requires effective treatment of industrial wastes, hence it is in the interest of the general public, the textile industry and the people and communities supported by it to obtain information on methods, problems and costs of treating textile wastes, and the relation of such costs to other components of the cost and income structure of the plants.

The study will cover all of the 32 sewered South Carolina municipalities which accept and treat textile wastes in their municipal sewage plants, and a substantial number of the 89 South Carolina wet- process textile manufacturing plants which operate waste-treatment facilities. Data will be obtained from the managers of the sewage systems and plants by means of questionnaires, from published reports, from the records of public agencies, and from consulting engineering firms which specialize in the design and operation of waste-treatment systems. The municipal phase of the study will precede the industrial phase.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1417, REMOVAL OF NITROGENOUS COMPOUNDS FROM A FERTILIZER PLANT EFFLUENT USING A MODIFIED OPERATION OF CONVENTIONAL WASTE TREATMENT SYSTEMS

E.C. BINGHAM, Farmers Chemical Assn. Inc., *Harrison, Tennessee* 37341

The primary objective of the project is to evaluate the technical and economic feasibility of reducing high concentrations of nitrogen by use of conventional treatment techniques with specific modifications. The study will determine the effects of selected variables on nitrogen removal, collect operational data to develop design criteria for other projects of a similar nature and examine the feasibility of reuse of certain wastestreams. In operation, high concentrations of ammonia will be reduced by stripping in a countercurrent aeration tower and the remaining ammonia will be oxidized to nitrates in existing trickling filter sewage plant. Nitrates will be denitrified to nitrogen gas under anaerobic conditions in facultative stabilization ponds. The feasibility of ammonia removal by an ion exchange or chemical precipitation process will also be investigated. Initial laboratory studies to determine approximate loadings and detention times to employ in the various treatment processes are currently underway in the laboratories of Associated Water and Air Resources Engineers, Inc. at Nashville, Tennessee.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1418, THE EFFECTS ON RUNOFF, GROUNDWATER, AND LAND OF IRRIGATING WITH CATTLE MANURE SLURRIES

J.J. SEWELL, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916

Hydraulic cleaning of dairy barns saves labor and improves sanitation; however, large quantities of manure slurry are produced. This slurry can be spread on fields by irrigation. The objectives follow: (1) determine the effects of ground slope, ground cover, and season on the maximum allowable slurry application rates, (2) learn the effects of continued slurry irrigation on groundwater quality and surface runoff and (3) develop slurry irrigation management techniques which minimize groundwater, land, and stream pollution.

A manure slurry holding tank equipped with agitation and slurry irrigation equipment will be constructed on a research dairy farm. A series of field plots will be planted to pasture and a

silage crop. The crops will be irrigated, and slurry runoff data and crop-yield data will be recorded during the season. Water from groundwater wells in the vicinity of the plots will be analyzed to determine coliform count, total bacteria count, nitrate level, phosphate level, BOD, pH, alkalinity, and water hardness. Management practices minimizing water and land pollution while being workable from the producer's point of view will be developed.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1419, DEWATERING AND DRYING OF SLUDGE ON POROUS MEDIA
K.B. SCHNELLE, Vanderbilt University, School of Engineering, *Nashville, Tennessee* 37203

The dewatering and drying of sewage sludge is most commonly carried out in porous supporting media such as sand over a soil in a drying bed. Dewatering takes place as the water in the sludge simultaneously filters down through the porous supporting media and evaporates from the surface of the bed into the atmosphere. As the dewatering takes place moisture gradients are established and in turn provide the driving force for the diffusion of the moisture to the surface of the bed and the subsequent further drying of the sludge. Sludge, being a porus colloidal substance, often biologically unstable even if digested, forms a highly compressible structural lattice of low tensile strength as it dries. This weak lattice structure results in a decrease in permeability as well as surface cracking as the material dries.

The proposed research evolves around the determination of moisture gradients and transport rates within the supporting media, the sludge, and the air-vapor boundary layer in the atmosphere. Gamma ray spectroscopy will be used to ascertain the changes in moisture without disturbing the flow system. These measurements will be used to establish the dewatering and drying rate of sludge under various climatic, operating and design conditions.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

2.1420, A STUDY OF SOME OF THE FACTORS WHICH INFLUENCE THE EFFICIENCY OF OXIDATION PONDS IN THE TERTIARY TREATMENT OF WASTE WATER
H.D. MCAFEE, Univ. of Texas, Undergraduate School, *Arlington, Texas* 76010

Efforts will be made to determine the effect of chemical characteristics of waste water on the production of chlorophyll by algae.

We will furthermore attempt to establish a more concise relationship between phosphates in water and algal growth.

Samples of water to be tested will be taken from oxidation ponds at the sewage disposal plant of the Trinity River Authority at Grand Prairie, Texas.

This work will fall in the category, Water Quality Management and Protection and will begin in September, 1970.

SUPPORTED BY University of Texas - Austin

2.1421, INVESTIGATION OF RICE IRRIGATION RETURN FLOWS - TEXAS COASTAL PRAIRIE REGION
C. TUCK, State Water Development Board, *Austin, Texas* 78711

The quantity and quality of irrigation return flow water from rice culture is being investigated for future planning of the return flows available for reuse in the Texas Coastal Prairie Region. There are two sample study areas in the project. One area uses a ground water supply and is instrumented for continuous operation. The other area uses a surface water supply and is being studied on a reconnaissance level.

The quantity of return flows will be obtained on a percent basis and/or on an acre-feet/acre basis from the records of water diversions, rainfall and volume of drainage that are collected. The quality of these return flows are analyzed from samples taken to investigate the possible change in water quality due to fertilizers and pesticides used in the culture of rice farming.

SUPPORTED BY Texas State Government - Austin

2.1422, DOCUMENT PROCESSING IN THE AREA OF WASTEWATER TREATMENT
E.F. GLOYNA, Univ. of Texas, School of Engineering, *Austin, Texas* 78712

The objective of this proposal is to provide the Water Resources Scientific Information Center with abstracts of articles, reports, books, etc. which deal with the general subject of wastewater treatment. Specifically, the scope of this proposal includes an abstracting service, transcription of abstracts on a prescribed format, and the development of a detailed bibliography of documents not abstracted on regular scheduled intervals. Procedures implemented to provide the abstracting service are as follows: a. Copies of selected periodicals and other pertinent publications will be obtained from Librarians as they become available. b. Selected publications will be reviewed by faculty and research staff members to establish a priority in listing articles to be processed. c. Draft abstracts for high priority articles will be prepared by a professional staff member assigned to the 'Center of Competence.' d. Draft abstracts will be reviewed periodically for technical accuracy by members of the Faculty Advisory Committee. Changes recommended by these specialists will be incorporated in the draft abstracts. e. Abstracts prepared in final form will be in accordance with WRSIC guidelines.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1423, PROCESS MODELING OF BIOLOGICAL WASTE TREATMENT
D.M. HIMMELBLAU, Univ. of Texas, School of Engineering, *Austin, Texas* 78712 (DADA17)

Technical Objective: To increase available knowledge on biological mechanisms of sewage treatment in order to improve quality of waste water treatment thereby reducing environmental pollution from military installations.

SUPPORTED BY U.S. Dept. of Defense - Army

2.1424, DEVELOPMENT OF WASTE TREATMENT SYSTEMS ABOARD MARINE AND FRESH WATER CRAFT
W.B. DAVIS, Texas A & M University System, School of Engineering, *College Station, Texas* 77843

This project will be responsible for the development of waste treatment systems which can be used aboard existing marine and fresh water craft. The waste treatment system will include some of the features of existing biological systems, but will be designed to be used under pressure using sound for mixing. The system will be tried on a number of different types of waste which will simulate the treatment efficiency aboard various size marine vessels. The systems will be designed for minimum contact and low detention times with high efficiency of treatment.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1425, MANAGEMENT OF INDUSTRIAL WASTE DISCHARGES IN COMPLEX ESTUARINE SYSTEMS
R.W. HANN, Texas A & M University System, School of Engineering, *College Station, Texas* 77843

This project is concerned with investigations of the quantity and quality parameters relevant to a consistent water quality management program for the Houston Ship Channel-Galveston Bay Estuary System. Included are data collection and evaluation on such parameters as salinity, diffusion patterns, water and industrial effluent quality, benthal deposits, and other pertinent variables.

Results of the data are to be translated into a management scheme which provides for achieving water quality standards in an orderly and efficient manner.

The final phases of the study are to be devoted to developing a three-dimensional dynamic model of the entire estuarine system for precise management of industrial waste discharge throughout the entire region.

2. WATER QUALITY

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1426, WATER RESOURCE SYSTEM OPTIMIZATION BY GEOMETRIC PROGRAMMING
W.L. MEIER, Texas A & M University System, School of Engineering, *College Station, Texas* 77843

Techniques useful in the optimization of water resource system design problems will be developed in this research. A new and powerful optimization method, geometric programming, will form the basis for this study. Using geometric programming, highly nonlinear problems may be solved with relative ease.

In this investigation, the geometric programming optimization technique will be applied to a variety of water resource design problems to tests its usefulness in design optimization. Two such problems are concerned with the optimal design of water treatment units and pipelines. A computer algorithm will be developed to make the geometric programming available for use by water resource analysts.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1427, TERTIARY TREATMENT BY COUNTER-CURRENT CARBON FILTRATION
T.D. REYNOLDS, Texas A & M University System, School of Engineering, *College Station, Texas* 77843

The purpose of the project is to develop a mathematical model for tertiary waste water treatment using counter-current moving-bed activated carbon filtration. The initial model was developed from the equation X/m equals Kt (n power) and constants are obtained from both tests. The initial model is C sub o minus C sub e equals Gamma sub c Q sub c (1-n power) KV (n power)/Q sub w, where X equals amount of organic absorbed, m equals amount of carbon present, t equals time of contact, n, K equals experimental constants, gamma sub c equals specific weight of grandular carbon, C sub o equals organic concentration in influent, C sub e equals organic concentration in effluent, Q sub c equals carbon volumetric flow rate, Q sub w equals water volumetric flow rate, V equals filter volume.

The primary parameter to be measured is total organic carbon, however, COD, BOD, phosphates and other parameters will be measured as deemed necessary to evaluate the model. Testing methods will involve batch testing, bench-scale counter-current apparatus and a 100 gallon per day pilot plant located at the University wastewater treatment plant.

2.1428, USE OF POLYMERS TO REDUCE OR ELIMINATE SEWER OVERFLOW IN THE BACHMAN CREEK SEWER
A.E. HOLCOMB, Dallas City Water Works, *Dallas, Texas* 75201

During periods of rainfall the Bachman Creek sewer receives excess quantities of ground or storm water due to infiltration. The flow exceeds the sewer line capacity resulting in untreated wastes overflowing into Bachman Creek causing pollution.

The project will identify the points of overflow. A portable injector system will be used to verify the best location for a permanent injector station for the polymers. A permanent automatic polymer injection station will be constructed and evaluated. Through the use of polymers, the flow in the sewer pipe will be increased thus, eliminating or greatly reducing the overflows. Design criteria, operating techniques, optimum polymer concentrations and other pertinent data critical to the intended use will be evaluated.

The project was started in the fiscal year of 1969 and will be completed in fiscal year of 1971.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1429, PHOSPHORUS REMOVAL AND DISPOSAL FROM MUNICIPAL WASTEWATER
C.H. CONNELL, Univ. of Texas, School of Medicine, *Galveston, Texas*

The objective of this project is to demonstrate effectiveness, feasibility and costs of biological, chemical and physical processes for removal and disposal of phosphorus from municipal wastewater.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1430, DEVELOPMENT OF SYSTEMS FOR GROUND WATER RECHARGE INTO THE OGALLALA FORMATION
M.J. DVORACEK, Texas Technological University, School of Agriculture, *Lubbock, Texas* 79409

The work proposed in this project is to develop systems for recharging underground formations. Several approaches - well, pit, basin, shaft, & trench recharge plus water spreading - will be investigated. Particular consideration will be given toward development of a filter or clarification system for removal of the high sediment load carried by waters used for recharge. Waters available for recharge are generally excess water such as surface runoff collecting in natural depressions (playas).

Investigation will include both field and laboratory installations of filter systems suitable for clarification of waters for both pit and well recharge. Pit, shaft, & trench recharge and water spreading will be primarily field evaluations of constructed recharge facilities. The establishment of design criteria for pits, shafts & trenches and filters for clarification of water is the primary objective of the project.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1431, EFFECT OF UNLINED TREATED SEWAGE STORAGE PONDS ON WATER QUALITY IN THE OGALLALA FORMATION
D.M. WELLS, Texas Technological University, Water Resources Center, *Lubbock, Texas* 79409

Treated effluent from approximately eighty municipalities located in the high plains of Texas is presently being stored in unlined ponds and used for irrigation of crops. This project is designed to determine the effect of such surface stored on groundwater quality in the underlying Ogallala formation.

A pond has recently been constructed for storing municipal effluent on the Texas Tech campus. Two wells will be drilled, cased, and equipped with electric pumps in the vicinity of this pond. One well will be located adjacent to the pond, and the other several hundred feet downstream. Samples will be collected weekly from these wells and from several other existing wells located in various distances around the pond. Weekly samples will also be collected from three or four points within the pond.

All samples collected will be analyzed for total nitrogen, total phosphorus, chlorides, and total dissolved solids. Changes in groundwater quality will be observed and quantitative estimates of the rate in which sewage percolates into the groundwater will be made by determining the rate and the extent of propagation of quality change from the test well adjacent to the storage pond.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1432, METHODS TO REDUCE WATER POLLUTION CAUSED BY STORM WATER SEWER LOADING BY USING FLUID FLOW FRICTION REDUCERS
H.R. CRAWFORD, Western Company, *Richardson, Texas* 75080

The research plan involves laboratory and field investigations directed at the use of high molecular weight polymers added to sanitary sewage with infiltrated ground water to demonstrate feasibility of reducing pipe friction loss with resulting increase in sewer flow rates.

Laboratory investigations shall consist of the following: 1. Small scale experiments on a water-polymer system to characterize friction reducing capabilities, storage life, toxicity, and effect as a coagulant. 2. Experiments to classify domestic sewage from chemical and physical properties. Field investigations shall consist of the following: 1. Testing on small scale models of a partial sewer system the friction reducing capability of selected polymers at varying sewage pipe depth and including surcharge. 2. Development of an injection device and method of injection of the polymer into the sewer pipe. 3. Determine the best location for injecting polymer into sewer pipe.

Laboratory and field data would be correlated for application in a full scale test of polymers added in a sanitary sewer infiltrated with ground water and in a waste water treatment plant.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1433, DEVELOPMENT AND DEMONSTRATION OF MATERIALS TO REDUCE OR ELIMINATE WATER INFILTRATION INTO SEWERAGE
H.R. CRAWFORD, Western Company, *Richardson, Texas* 75080

The research plan involves laboratory and large-scale investigations directed at the development of a chemical sealant to prevent ground water infiltrations into sanitary sewers and its feasibility in application.

Laboratory investigations shall consist of the following: 1. Small scale experiments to determine the most promising sealant formulations according to the following properties: a. Bonding ability b. Strength c. Variable cure time d. Ease of handling e. Stability f. Cost 2. The following parameters will be utilized in evaluating the sealant formulations: a. Tensile strength through the bond between cured sealant and the conduit. b. Flexural strength of cured sealant material. c. Environmental tests of cured sealant material.

The large-scale investigation shall consist of further screening of sealant formulations in a sewer line mock-up with a controlled environment. This will include an investigation and evaluation of existing equipment to apply the new sealant.

At the conclusion of the program recommendations will be made for a chemical sealant to prevent ground water infiltration and needed improvement and/or development for application of the sealant.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1434, TREATMENT OF OIL WASTES
M. WHITEFIELD, Western Company, *Richardson, Texas* 75080

The objective of this project is to prevent pollution by gelling the oil contained in a damaged tanker. The solidified oil will prevent the pollution of the ocean and the beaches since it will be confined to the tanker.

The purpose of this project is to develop materials and equipment for the gelling of crude oil contained in an oil tanker. Included as a part of the purpose will be a literature survey, a gelling material survey, the improvement of gelling materials, a schematic design of a system for off-loading of the gelled oil, and a system designed for gelling the oil in a tanker. In addition to laboratory oil gelling tests, the better materials will be used to get crude oil in a 1,000 and a 25,000 gallon test tank.

The final report on this project will include the major accomplishments and results of the project including the identification of the best gelling materials, the economics of a gelling system, and an injector system design.

The project was initiated in fiscal 1969 and will be completed in fiscal 1971.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1435, STUDIES TO DEVELOP PROCESS DESIGNS FOR EFFLUENT QUALITY CONTROL
L.L. HISER, Southwest Research Institute, *San Antonio, Texas* 78228

No summary has been provided to the Science Information Exchange.

SUPPORTED BY No Formal Support Reported

2.1436, THERMODYNAMICS OF WASTE STABILIZATION PONDS
D.W. HENDRICKS, Utah State University, Utah Water Research Laboratory, *Logan, Utah* 84321

The project objective is to model the flow of free energy through a waste stabilization pond system, with principal emphasis on the primary pond in the initial stages.

The thermodynamic model will provide a scientific basis for recommending rational design criteria for waste stabilization ponds. The thermodynamic model will allow identification of adjustments in design that will maximize the energy degradation in the reactor and minimize energy production (photosynthesis).

The procedure is to delineate important reactions in each thermodynamic zone and develop a theoretical model; this model will be qualitatively and quantitatively ascertained through field measurements on a prototype system.

2.1437, ENVIRONMENTAL GEOLOGY OF SELECTED PARTS OF NORTHWESTERN VERMONT
W.P. WAGNER, Univ. of Vermont, School of Arts, *Burlington, Vermont* 05401

The objectives of the proposed project are: (1) to evaluate the water supply potential of the Champlain Valley, by delineating aquifers, water table elevations, recharge areas, and aquifer capacities; (2) to locate and evaluate suitable sites for garbage dumps in the Champlain Valley; (3) to determine septic waste disposal potentials of selected upland areas by mapping the distributions and evaluating the characteristics of unconsolidated materials; (4) to evaluate the nature, occurrence, and extent (rates) of stream bank and beach erosion.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1438, A STUDY OF NATIONAL POLICY ALTERNATIVES FOR URBAN WATER MANAGEMENT
A.B. BIGLER, U.S. Natl. Water Commission, *Arlington, Virginia* 22203

The objective of the study is to provide a comprehensive analysis of the water problems of metropolitan regions, including waste disposal problems, to ascertain the scope and nature of the programs required to meet the needs of such regions, and to develop alternative policy proposals. The study tasks will include: (a) formulation of alternative goals and objectives for urban water management; (b) identification of the planning, decision-making and implementation phases for urban water management; (c) analysis of cost-sharing and benefit allocation practices in urban water management; (d) determination of operational procedures and techniques for managing urban water facilities and related land and water resources; and (e) development of alternative approaches to urban water management and identification of the corresponding national water policy impact requirements. The plan of investigation includes literature surveys, interviews, and analysis of selected metropolitan case study areas.

The study was initiated in fiscal year 1970 and will terminate in fiscal year 1972.

SUPPORTED BY U.S. National Wtr. Comm. - Arlington, Va.

2.1439, ADVANCED WASTE TREATMENT FOR WATER REUSE - STATE OF THE ART
J. GAVIS, U.S. Natl. Water Commission, *Arlington, Virginia* 22203

The objective of the investigation is to: 1. Review the present state of the art in the development of methods for intensive treatment of waste waters to facilitate reuse. 2. Assess the feasibility of increase of water supply by means of advanced waste treatment processes to allow reuse of sewage treatment plant effluents.

The plan of the investigation is to review the current literature and to interview engineers and scientists engaged in research and development of advanced treatment methods. The project was started in fiscal year 1969 and will terminate in fiscal year 1970.

SUPPORTED BY U.S. Executive Office - Natl. Water Comm.

2.1440, THE EFFECT OF DETERGENTS ON THE OXYGENATION OF WATER
J.A. CASKEY, Virginia Polytechnic Institute, Graduate School, *Blacksburg, Virginia* 24061

Although many studies have been made showing that surfactants can lower oxygenation rates the mechanism by which this occurs is not known. The purpose of this investigation is to study what part of the surfactant molecule is responsible for this interfacial resistance to oxygenation. To this end the effect of following parameters on the interfacial resistance will be studied: hydrophobic chain length, hydrophilic functional group, surface

orientation and counter ion effect. Pure surfactants will be used so that the resistance can be related to the surface concentration by means of Gibbs' adsorption isotherm.

A quiescent liquid manometric gas absorption contactor will be used for the study. From this investigation it is hoped that it will be possible to specify what type of detergent is needed to increase the capacity of existing activated sludge units in municipal waste treatment facilities.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1441, TREATMENT OF DYEING BATH WASTE STREAMS BY FOAMING AND FLOTATION TECHNIQUES
D.L. MICHELSEN, Virginia Polytechnic Institute, School of Engineering, *Blacksburg, Virginia* 24061

The treatment of waste streams from dyeing operations is a problem in industrial waste treatment centering in the southeastern states. The proposed research plan will be the study of waste treatment and color removal of dispersed dye bath waste streams using foaming techniques. The initial stream to be studied will be a synthetic black or blue-black dispersed dye formulation including carrier approximating waste stream conditions from the dyeing of polyesters (Dacron) and triacetate rayon. The object of the work will be to study the removal of color, carrier (solvent), and perhaps dispersant surfactant using foam fractionation, adsorptive bubble fractionation and homogeneous ion flotation (complexing). Various parameters will be studied.

Depending on the outcome, the treatment of waste streams from other types of dyeing procedures may be tested using foaming techniques.

Some exploratory work on the removal of dissolved phenol and phenol derivatives from water may also be explored. This problem is pertinent to waste treatment because of toxicity and fish taste.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1442, OPTIMAL CONDITIONING PROCEDURES FOR WASTE ACTIVATED SLUDGE DISPOSAL
C.W. RANDALL, Virginia Polytechnic Institute, School of Engineering, *Blacksburg, Virginia* 24061

The proposed research plan involves laboratory investigations of the relative merits of biological and chemical waste activated sludge conditioning procedures. The approach of the investigation is to evaluate the effect of processes such as anaerobic digestion, aerobic digestion, and chemical conditioning on the overall sludge volume reduction rate.

Specific research objectives are: 1. To determine the comparative extents and rates of waste activated sludge destruction that can be obtained with anaerobic and aerobic digestion. 2. To evaluate the effect of anaerobic digestion on the subsequent dewatering rates of activated sludge as compared to the effect of aerobic digestion. 3. To evaluate the feasibility of using polyelectrolytes to conditioning anaerobically and aerobically digested activated sludge prior to dewatering. To measure the relative quality and quantity of waste liquid produced by the various conditioning processes.

The data will be correlated to define an optimum dewatering process for both sand bed and mechanical processing.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1443, PROCESSING PLANT EFFLUENTS FOR IRRIGATION IN COASTAL PLAINS OF NORTHEAST
G.A. PEARSON, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Norfolk, Virginia* 23501 (SWC-019-ANOR-1)

OBJECTIVE: Investigate waters of inferior quality, such as processing plant effluents, in regard to problems related to land disposal, and potential use for supplemental irrigation of crops; evaluate effects of these waters on plant growth and soil physicochemical properties.

APPROACH: Coordinated laboratory-greenhouse-field research program designed to evaluate the effects of these effluents on soils, crops and ground water when used for supplemental irrigation and for land disposal. This program is in initial planning stages.

PROGRESS: In compliance with restrictions on the indiscriminate discharge of waste water into streams, many vegetable processing plants have installed sprinkler irrigation systems to spread their waste water onto woodland or grassland for disposal. Effort is being made to utilize this waste water for irrigation. Because of its composition care must be exercised. In one study sprinkler irrigation with effluent from a plant using lye-peeling of potatoes caused severe soil damage in one season. Structure of top soil was altered, hydraulic conductivity was virtually zero, soil was covered with half-inch thick mat of potato peels and skins. This covering effectively sealed the soil surface creating anaerobic conditions. No vegetation was growing on the soil.

SUPPORTED BY U.S. Dept. of Agriculture

2.1444, INVESTIGATION OF RECOVERY OF LARGE MARINE OIL SPILLS BY USE OF A VORTEX ASSISTED AIR LIFT
P.C. WALKUP, Battelle Memorial Institute, *Richland, Washington* 99352

Efforts to recover spilled oil from recent marine disasters have shown that airlift recovery systems are effective and relatively efficient in calm waters. The purpose of this study is twofold: 1) investigate the feasibility of assisting an airlift recovery system by drawing the spilled oil to a central location with the gravity depression created by the vortex and 2) investigate the wave suppression effects of an induced vortex. Test apparatus has been installed in a 432 foot by 209 foot by 16 foot deep water basin consisting of a vortex generator with capabilities up to 6000 gpm and intake piping up to 18 inches in diameter, a wave suppression device, a wave making device and an airlift oil recovery system. Data will be gathered on wave height and length of both the generated and suppressed waves and the vortex profile through a broad spectrum of wave action. Tests will be conducted with a variety of oils having high potential for marine spillage, high gravity crude, low gravity crude, Bunker 'C' etc. and analysis will be made of the cohesive drawing of the oil as influenced by the induced vortex. It is expected that these and other data will be used to optimize the design of an open sea oil recovery system. This project was started FY 1969 and is expected to be completed by FY 1970.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1445, REDUCTION OF RADIOISOTOPES IN HANFORD REACTOR EFFLUENTS
R.G. GEIER, Douglas United Nuclear Inc., *Richland, Washington* 99352

The radionuclides in Hanford's reactor effluent are formed by neutron activation of salts not removed in the water pre-treatment process, salt additives, and corrosion products which adhere to the reactor coolant lines as a film long enough to become significantly activated.

This research includes both laboratory and in-reactor studies of the three methods of reducing effluent radioactivity: better methods of pre-treatment, reducing film adherence time, and effluent treatment.

SUPPORTED BY U.S. Atomic Energy Commission

2.1446, RECOVERY OF BY-PRODUCTS FROM SHELLFISH WASTE
Q.P. PENISTON, Food Chemical & Res. Labs., *Seattle, Washington* 98107

The purpose of this project is to develop a new process to use waste material from shellfish processing operations to manufacture useful products. The work is planned to result in information sufficient to design a commercial scale plant to apply this new process.

The wet waste material is collected and brought to a central processing site. It is than ground and extracted with dilute sodium hydroxide to remove the protein. Protein is precipitated and spray dried to result in a product that contains approximately 90% protein. The remaining shell is then treated with hydrochloric acid to remove the mineral matter. The product from this step is a calcium chloride brine useful as an industrial chemical. The

remaining shell consists principally of chitin which is further purified, bleached, and transformed into chitosan for use in special applications.

This work was initiated under contract in FY 1969 and will continue in FY 1970. The process is now being proposed for a research demonstration grant to the Federal Water Pollution Control Administration by the City of Kodiak.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1447, WASTE WATER ODOR REDUCTION MECHANISMS IN SOIL FILTERS
D.A. CARLSON, Univ. of Washington, School of Engineering, *Seattle, Washington* 98105

The purpose of this study will be to investigate the processs involved in the removal of odorous compounds in soil filters. Previous work at the University of Washington indicates that the process of hydrogen sulfide degradation in soil filters is biological in nature, but further research is needed to establish the organisms responsible, to attempt pure culture studies with isolated colonies to verify column activity, and to establish optimum conditions for their growth and ability to degrade test compounds.

Other phases of the research will consider changes in soil properties during test gas application, accumulation of deposited products in the soil, gas pressure requirements under various gas flow conditions and development of optimum conditions for long period use of soil filters.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1448, STREAM STRIPPING OF KRAFT PULP MILL EFFLUENT STREAMS
J.L. MCCARTHY, Univ. of Washington, School of Engineering, *Seattle, Washington* 98105

The broad objective of the presently proposed research is to improve the effectiveness and to extend knowledge concerning the possible industrial applications of the 'SEKOR' process which in, essence, comprises the counter-current steam stripping of kraft pulp volatile organic compounds from the fluid and thereby provide relatively clean effluent water which can be reused in pulp mill process or else discharged without danger. The volatilized organic substances are condensed to yield water-immiscible 'SEKOR oils' which may find uses in commerce. Use of the process may also result in a substantial decrease in the odorous substances emitted into the atmosphere from kraft pulp mills.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1449, POLLUTION PREVENTION BY AERATION OF FRUIT PROCESSING WASTES
L. ESVELT, Snokist Growers, *Yakima, Washington*

The project involves a study of three methods of aerobic biological treatment of wastes from a fruit processing plant. The methods to be studied include a completely mixed aerated lagoon, a completely mixed activated sludge system, and a modified contact stabilization process. Oxygen transfer rates and utilization rates will be determined, and sludge dewatering studies will be made. A study of possible installation of solids removal equipment in the plant will be made as a possible method of reducing waste volumes and of reducing sugar leading into the carriage waters.

SUPPORTED BY U.S. Dept. of Interior - F Wtr. Qua. Adm.

2.1450, A DEMONSTRATION OF A NEW MINING TECHNIQUE TO PREVENT THE FORMATION OF MINE ACID IN AN ACTIVE DEEP COAL MINE
S. BARKER, Island Creek Coal Company, *Holden, West Virginia* 25625

Summary of Proposed Work: The project is Phase I of a four part program, being conducted under a Research and Development Grant, to demonstrate that mining coal in an oxygen-free atmosphere will prevent the formation and subsequent discharge of acid mine water into streams and other water courses. Investigation and demonstration of the adaptability of life support systems, similar to those used by NASA in the space program, to conventional coal mining techniques will aid in determining the feasibility of mining coal in an oxygen-free atmosphere. Other benefits expected include the reduction of chances for explosions and fires in a mine and a decrease in the occurrence of lung disease in miners. This study will further research of the inert gas atmosphere technique which has been performed in laboratory bench scale studies of inert gas atmosphere effects on pyrites, and the experimental application of inert gas atmospheres to abandoned mines. The purpose of the Phase I study is to make engineering evaluations of life support systems, in-mine systems, outside systems, and facilities, personnel programs, mine sites exploration and evaluation, safety, and planning associated with continuation of the project into the additional phases initially delineated (component evaluations, construction and operation of a demonstration mine and project evaluation and final report).

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1451, PHOSPHATE UPTAKE, STORAGE, AND RELEASE BY MICROORGANISMS IN WASTEWATER TREATMENT
W.A. SACK, West Va. University, Water Research Institute, *Morgantown, West Virginia* 26506

The objective of this investigation is to understand and develop the capability of heterotrophic microorganisms to remove phosphate from wastewater. The first phase of the work will seek to determine how the uptake and turnover of phosphorus depend on the presence and level of a metabolizable substrate. Batch and continuous culture techniques will be used to simulate in a controlled manner the actual conditions of sludge contact with waste. The substrate-to-microorganism ratio will be varied over a wide range to observe the phosphate uptake per cell in growth situations. To closely follow the flow of phosphate, rigorous phosphate balances will be made on the cell mass and substrate. The second phase of the study will be an investigation of cellular storage of phosphate. Complex polyphosphates accumulate in a wide variety of organisms under certain conditions which limit their usual synthetic activities toward growth and division. In waste treatment systems, carbon is the parameter limiting cellular growth. Observations therefore will be made for inorganic polyphosphate storage under carbon limiting conditions. The substrate limitation will be enforced on the culture under various patterns and cycles of loading.

Estimates of stored polyphosphates will be made by staining procedures and by chemical analyses. Chemically defined media will be used. Pure cultures and mixed cultures representative of those found in wastewater will be employed.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1452, MINE SPOIL POTENTIALS FOR WATER QUALITY AND CONTROLLED EROSION
R.M. SMITH, West Va. University, School of Agriculture, *Morgantown, West Virginia* 26506

Test core and blast hole samples of strata overlying coal considered for strip mining will be evaluated chemically, physically, and mineralogically to determine desirability for soil formation and unpolluted seepage and runoff waters. Forms of sulphur, carbonates, mineral species, buffering capacities, soluble or exchangeable plant nutrients or toxic elements, and weathering changes over time in environments of spoil deposits will be studied to guide plans for coal stripping operations, placement of different spoils and practices necessary for prevention of water pollution, improvement of the environment for planned uses, and expansion of results to areas other than Northern West Virginia.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1453, THE THICKENING AND DEWATERING OF PRECIPITATES FROM THE LIME/LIMESTONE TREATMENT OF MINE DRAINAGE
E.B. WILSON, West Va. University, School of Mines, *Morgantown, West Virginia* 26506

2. WATER QUALITY

The proposed work will consist of a detailed study of the problem of densification of ferric hydroxide--calcium sulfate sludges which result from the lime or limestone treatment and aeration of acid waters from coal mines. The project will focus on the interrelationship of mine wate chemistry with the settleability of sludges and possible methods used to chemically or mechanically concentrate and dewater these sludges. Areas of study will include filtering, flocculation, decantation, centrifuging, thickening, and cycloning. A State of the Art review of potentially useful existing dewatering methods as they apply to mine water treatment sludges will be completed early in the study. The economics of alternative treatment schemes will be examined with the objective of reducing the overall costs of water treatment and sludge disposal. The project will begin in February, 1970, and is scheduled for completion in January, 1972.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1454, COMBINED STEEL MILL AND MUNICIPAL WASTEWATERS TREATMENT
W.M. SMITH, Natl. Steel Corporation, *Weirton, West Virginia* 26062

The project is Phase I of a proposed three part program, being conducted under a Research and Development Grant, to demonstrate new and unique methods of treating selected steel mill and sanitary wastewaters in a municipal sewage treatment plant. The synergistic properties of the various wastewaters will be utilized to maximize the cost effectiveness of maintaining the stream quality objectives. Phase I consists of three tasks. Task I includes characterization of the steel mill wastes, evaluation of existing wastewater treatment facilities, determination of the quantity and quality of wastes to be treated, performance of a survey of the municipal treatment facility to evaluate processes to upgrade the plant to meet new standards, estimation of the overall effects of increased discharges in the Ohio River from larger volume mill effluents, determination of the hydraulic adequacy of the sewer system with regard to storm runoff, and evaluation of the effects of mill waste waters on sewer system materials of construction. Task 2 provides for the assessment of alternative treatment processes for combined steel mill and municipal wastewaters, utilizing laboratory and bench-scale studies. The most effective treatment processes for a demonstration project will be evaluated in Task 3, based on Task 2 data.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1455, COMBINED INDUSTRIAL AND MUNICIPAL WASTE TREATMENT
D. MARTIN, Green Bay Met. Sewage Dist., *Green Bay, Wisconsin*

The project will be a study, evaluation, and determination of the effectiveness, design, and operating parameters of four alternative biological treatment processes and modifications for treating combined municipal and industrial (primarily paper mill) waste waters. A pilot waste water treatment plant for each process will be determined. Each pilot plant will have a 1 to 10 gpm capacity for combined waste waters. After selecting the most promising process, an existing 60 gpm pilot will be modified to suit the selected process and will be operated for a year to demonstrate its performance and to generate performance data. The final objective is to evaluate the design, performace, and use of the systems and to generalize the results for applicability to other locations.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1456, DEMONSTRATION PROJECT OF BIOLOGICAL ADSORPTION OF POLLUTANTS FROM COMBINED STORM WATER RUNOFF AND SANITARY SEWAGE
F.I. VILEN, Kenosha City Water Utility, *Kenosha, Wisconsin* 53140

The project objective is to provide a means for high rate biological adsorptive treatment of combined sewage by the utilization of viable activated sludge, clarification, and disinfection. The method will be to store activated sludge in a biosolids reservoir and maintain a contact tank and a solids stabilization tank in an empty and ready condition at a location adjacent to the sewage treatment plant. When a rain event occurs, the excess combined sewage is directed to the contact tank and the activated sludge solids proportioned in. After a contact period (15 - 30 minutes) during which pollutants are adsorbed by the biosolids, the mixed liquor is discharged to a clarifier for solids/liquid separation. The effluent is disinfected and discharged to receiving waters. The sludge solids are discharged to the stabilization tank and reused or sent to digestion facilities as required.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1457, RESEARCH AND REFERENCE TO SEWAGE EFFLUENT PONDS
W.C. BOYLE, Univ. of Wisconsin, School of Engineering, *Madison, Wisconsin*

The objective of this investigation was to determine base design criteria for effluent stabilization ponds in Wisconsin by ascertaining the effects of detention time, organic loading and temperature on pond efficiencies. By the use of two partitions a 5 foot deep pond was converted into each of three ponds, approximately 35' by 35'. Secondary domestic sewage effluent was fed on a controlled basis to these three ponds to give the following detention times; 3, 10 and 30 days. The effects of these different detention times were determined at various temperatures and organic loadings by conducting tests throughout the year.

The performance of these ponds under different experimental conditions were determined by use of the following analytical tests: B.O.D., C.O.D., solids, nitrogen, bacteriological (mainly fecal coliform), and phosphorus. In addition, algae and plant studies were conducted, dissolved oxygen and temperature profiles were measured and actual detention times were measured by means of dye tracer techniques.

This study, conducted in connection with the Ixonia (Wisconsin) activated sludge treatment plant, was started in the fiscal year of 1966 and is expected to be completed by December, 1969.

SUPPORTED BY Wisconsin State Government - Madison

2.1458, APPLICATIONS OF AGGLOMERATE SIZE MEASUREMENT TO PROBLEMS IN WATER RESOURCES MANAGEMENT
R.K. HAM, Univ. of Wisconsin, School of Engineering, *Madison, Wisconsin*

Agglomeration is one of the most basic and common unit processes to be found in natural and man-made water systems; yet, there is need for improved utilization of the process, as might be attained once the process is better understood, to meet contemporary problems of water resources management and control.

This study is expected to provide for monitoring the dynamic process of agglomeration and should lead directly to improved process applications. It is based on the use of a concentric cylinder device which incorporates a specially designed particle size analyzer for monitoring certain properties of agglomerates as they are formed in the annulus.

This study is divided as follows: 1. An apparatus is devised to measure fundamental changes occurring during agglomeration processes. 2. The apparatus is applied to work on the agglomeration of organic and inorganic colloidal matter. In particular, the effects of shear rate and agglomerate concentration are examined. 3. The above results are applied to use of the unit on other agglomeration processes, including the precipitation of phosphates, hardness, and iron or manganese; and the flocculation of biological systems, such as bacteria in the activated sludge process, or algae in nutrient removal processes.

2.1459, DEVELOP FIELD PROCEDURES FOR PREDICTING MOVEMENT OF LIQUID WASTES IN SOILS
F.D. HOLE, Univ. of Wisconsin, Graduate School, *Madison, Wisconsin*

Hydraulic conductivity of a volume of soil approximately 4 in. (10 cm.) in diameter will be measured under saturated condi-

tions in major horizons of several representative soils of Wisconsin. Measurements in situ will be made with the Bouwer double tube apparatus (with a hydraulic head of nearly 2 meters) developed in the U.S.D.A., Research Service Laboratory at Phoenix, Arizona. This first application of this new rapid field method to Wisconsin soils will be related to standard soil percolation tests required by state law to determine suitability of soils for septic tank installations. Correlative analysis of soil fabric and laboratory tests of undisturbed soil cores will be made. On the basis of the data, evaluations will be made of (a) current concepts of hydraulic properties of soil horizons and entire profiles, (b) the standard percolation test, and (c) possible future approaches to research problems encountered during the course of this study. The project began on July 1, 1969 and will be completed on June 30, 1971.

SUPPORTED BY Wisconsin State Government - Madison

2.1460, DEFINITION OF THE MIXING ZONE FOR WASTE EFFLUENT DISCHARGED INTO SURFACE WATERS

J.A. HOOPES, Univ. of Wisconsin, School of Engineering, *Madison, Wisconsin*

The objectives of this project are: (1) Determine the mixing zones for three or four waste effluents in well defined field environments, using ground and aerial sampling methods; (2) Develop a detailed experimental program to test simple, idealized laboratory models of outfall discharges into river and lake environments; and (3) Analyze and interpret the summer field surveys in light of the mixing zone hypothesis, developed during the first year of this study, and the laboratory model observations.

During the summer of 1969, field surveys of the pollutant patterns from municipal, powerplant and other industrial waste discharges into three or four Wisconsin rivers will be made. These surveys will include the measurement of depth, velocity, temperature and pollutant concentration both along and across the river, downstream of the outfall. Simultaneous with the ground sampling, aerial photographs of the pollutant patterns will be taken. Field sites will be selected in order to include different river and effluent conditions.

In an effort to extend and generalize these field observations, simple, idealized laboratory and mathematical models of waste effluent discharges will be studied. These models will be used to study the effects of outfall location and type and river discharge and geometry on the rate of dilution or mixing of the effluent with the river.

Based upon upon these studies, it is hoped that: (1) more definitive criteria regarding the mixing zone can be developed; (2) the proper location of sampling or monitoring stations can be prescribed; and (3) criteria on the location and design of outfall structures to maximize the rate of effluent dilution in different river environments will result.

SUPPORTED BY Wisconsin State Government - Madison

2.1461, INVESTIGATIONS OF ZOOGLOEAL FLOCS

G.A. ROHLICH, Univ. of Wisconsin, School of Engineering, *Madison, Wisconsin*

The proposed work has been divided into the following general areas: Floc Formation - studies are being undertaken to determine the quantitative and qualitative factors affecting the flocculation of bacteria of the genus Zoogloea.

Metabolism and Growth of Zoogloeal Species - Further work is being undertaken to better understand the metabolism of the Zoogloeal Species. Identification and taxonomic studies are also being made.

Kinetic and Diffusional Studies - The diffusion of nutrients (including oxygen) through pure culture floc is being studied. Both kinetic and diffusional models will be investigated and tested.

Gravity Settling of Flocs - Preliminary studies are being made to better ascertain the factors affecting the density, specific surface and shape of pure culture flocs that might affect settling properties.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1462, PILOT STUDIES IN THE RESTORATION OF THE PHYSICAL ENVIRONMENT OF A STREAM TO MAINTAIN A CLEAN WATER FLORA AND FAUNA

R.V. HARMSWORTH, Limnetics Incorporated, *Milwaukee, Wisconsin* 53218

The proposed study is to evaluate a method of accelerating the natural 'purification' processes of streams receiving shock loads of sewage effluent. The method proposed is a horizontal gravel filter, similar to the trickling filter of sewage treatment plants. The method also has possibilities for diverting some nutrients from the algal cycle to an animal food chain and would therefore have potential for retardation of the algal eutrophication process. The program consists of two parts and will take place over a two year period.

The pilot study is to determine the feasibility of building a biological reactor in which the proper ecological environment for the development of periphytic and planktonic communities will be established. The pilot study will also evaluate the effect of the reactor in developing diverse communities of organisms and improving water quality.

If the first year's program is successful, a full scale reactor will be built in the stream in the second year and the impact of the reactor upon the stream fauna and water quality evaluated. The pilot study will be undertaken on Jackson Creek at Delavan, Wisconsin.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1463, LUXURY METABOLIC STORAGE OF PHOSPHORUS IN THE ACTIVATED SLUDGE FLOC

S.K. MALHOTRA, Marquette University, School of Engineering, *Milwaukee, Wisconsin* 53233

The relative ineffectiveness of the activated sludge waste water treatment process in removing phosphorus is a major cause of progressive fertilization of natural bodies of water receiving treated waste waters. Phosphorus enrichment often results in algal blooms, which frequently result in objectionable odors and many other deteriorating effects on the quality of water.

Recently it has been reported that the activated sludge process can be adapted to make the organisms store phosphorus during their endogeneous respiration phase, far in excess of their metabolic uptake in the logarithmic growth and declining growth phases. This excess phosphorus uptake, 'Luxury Storage,' has also been reported to be affected by the cations in the environment.

The objectives are to examine the storage of phosphorus in the activated sludge flocs as the microorganisms pass through different growth phases, and to determine the proportions of the total stored phosphorus in each of the growth phases; the effects of ionic and surface adsorption and storage of phosphorus by cationic colloidal formations.

Batch processes with a synthetic substrate under controlled parameters of pH, food/microorganisms ratio, cationic concentrations, dissolved oxygen concentrations and the degree of mixing will be employed.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1464, PROCESSING RETORTING WASTE WATERS

A.B. HUBBARD, U.S. Dept. of the Interior, Bureau of Mines, *Laramie, Wyoming*

Detailed studies of waters produced during the retorting of oil shale will be made to: Determine what pollutants are present, demonstrate if any pollutants of value can be recovered to offset waste disposal costs, and develop methods for pollutant removal or disposal.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

2.1465, STUDY OF WASTE DISPOSAL PROBLEMS

J.R. RUARK, U.S. Dept. of the Interior, Bureau of Mines, *Laramie, Wyoming* 82070

2. WATER QUALITY

This project is directed toward the determination of organic and inorganic pollutants in process and product waters from an oil shale processing operation in order to devise methods for removing the contaminants or reducing their concentrations to harmless levels.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

2.1466, POLLUTANTS IN PRODUCT AND PROCESS WATERS FROM OIL-SHALE RETORTING OPERATIONS AND METHODS FOR THEIR REMOVAL
S.S. TIHEN, U.S. Dept. of the Interior, Bureau of Mines, *Laramie, Wyoming*

This project is directed toward the determination of organic and inorganic pollutants in process and product waters from an oil-shale processing operation in order to devise methods for removing the contaminants or reducing their concentrations to harmless levels.

Because Green River oil-shale deposits are located in arid or semiarid regions, process water will be scarce and provisions must be made for its reuse. It would also be desirable to augment existing water supplies by reclaiming the water product during retorting. In either case, the pollutants must be either removed or reduced to such low concentrations as to render them harmless. Detailed knowledge of the compositions and amounts of pollutants may be removed or reduced to harmless or unobjectionable levels. Organic contaminants might be present in sufficient quatities to make recovering them economically attractive.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

F. POLLUTION EFFECTS

Ecological, Physiological, and Physical Effects of Water Pollution.

2.1467, INTERACTIONS BETWEEN AQUATIC PLANTS AND SEWAGE EFFLUENT
D.E. DAVIS, Auburn University, School of Agriculture, *Auburn, Alabama* 36830

Five aquatic weed species, alligator weed (Alternanthera philoxeroides (Mart) Griseb), water hyacinth (Eichornia crassipes (Mart.) Solms), egeria (Egeria densa Planch), slender naiad (Najas flexilis (Willd) Rostk and Schmidt), and curly pondweed (Pontamogeton crispus L.) will be grown in 100% well water and in 75% well water and 25% sewage effluent. Experiments will be conducted in pools out-of-doors and in plastic pans in a growth chamber. The following determinations will be made: (1) effect of sewage effluent on the growth of the aquatic weeds and phytoplankton, (2) effect of the growth of aquatic weeds on the removal of nitrogen and phosphorus from the water and on the growth of phytoplankton, and (3) the amounts of protein, total nitrogen and phosphorous present in the different aquatic weed species grown in different sewage concentrations.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1468, DYNAMICS OF CHEMICAL & PHYSICAL CHARACTER OF WATER, BOTTOM MUDS & AQUATIC LIFE IN A LARGE IMPOUNDMENT ON A RIVER
J.M. LAWRENCE, Auburn University, Water Resources Research Inst., *Auburn, Alabama* 36830

This study of impoundments on parts of the Chattahoochee and Flint Rivers will supplement work completed under OWRR Project B-00 -ALA (Phase I). This study will indicate: (1) input-output relationships of salts and organic matter brought into the impoundment by creeks, streams and rivers and their distribution in water, biota and bottom muds within the impoundment and its tailwaters; (2) the influence of treated domestic pollution on chemical and physical characteristics of water throughout a long, relatively deep, power impoundment; (3) the importance of paper mill waste introduced into the prevailing domestic sewage pollution upon aquatic plant development and upon fish population conditions in downstream areas of such polluted impoundments; (4) critical periods and conditions that may affect aquatic life in this and similar impoundments; (5) the dynamics of physiochemical characteristics of mainstream impoundments and aid in the establishment of water quality criteria for multi-purpose impoundments.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1469, EFFECT OF POLLUTANTS ON AQUATIC MICROORGANISMS
W.C. NEELY, Auburn University, School of Arts, *Auburn, Alabama* 36830

Laboratory work will be conducted to determine the following: (a) The effect of typical pollutant molecules on sunlight mortality of and sunlight induced mutations in typical aquatic microorganisms. (b) The mechanisms by which these effects occur will be elucidated for various pollutants of different molecular structures.

The above information will be used to obtain a working relationship which will enable prediction of biological activity of a pollutant from knowledge of its molecular structure.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1470, EFFECT OF INDUSTRIAL POLLUTANTS ON WATER QUALITY
B.E. HUNTLEY, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Dauphin Island, Alabama* 36528

Objectives of the project are to determine if wastes from selected industrial complexes which are discharged into waters adjacent to the plant operations create environmental conditions conducive to bacterial multiplication. Wastes from paper mills and related industrial operations, for example, may discharge bacterial nutrients, such as xylose (wood sugar) into ponds or rivers. This would provide excellent nutritional conditions for growth of some bacteria including pathogens and organisms included in the coliform group used as indicators of fecal pollution. Growth of fecal coliform organisms under these conditions would lessen their value as indicators of fecal pollution.

Samples for bacterial analyses will be collected at points near waste discharge ports and at downstream sites along the flow route. Chemical analyses of the samples containing large numbers of bacteria will be conducted to determine the nutrient composition.

The project started in August 1969 and is continuing.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.1471, A BIOLOGICAL INVENTORY OF THE STREAMS AND IMPOUNDMENTS OF THOSE PORTIONS OF RIVER BASINS WITHIN 12 EAST CENTRAL ALABAMA COUNTIES
H.D. KELLY, State Game & Fish Division, *Eastaboga, Alabama* 36260

The purpose of this study is to collect biological data from the streams and impoundments as related to the fishery of these river basins as follows: I. Fish: a. Species, b. Species distribution, c. Food habits, d. Spawning data, e. Stream production (as indicated by population samples), f. Impoundment production (as indicated by population samples). II. Fish food organisms. III. Aquatic plants. IV. Sport fishery utilization. V. Commercial Fishery. VI. Effects of pollution.

Recent studies have indicated the pressures of an increased demand upon our waters by fishermen and others who use our waters in the years to come. It is felt that this information will better equip us to meet this challenge.

Period for this study: 10/65 - 9/73.

SUPPORTED BY Alabama State Government

2.1472, THERMAL AND CONVENTIONAL RIVER POLLUTION
L.P. MORIN, Univ. of Alabama, Research Institute, *Huntsville, Alabama*

Environmental studies on the ecological requirements of aquatic organisms associated with the Tennessee River and its watershed begun several years ago are being continued. The portion of the river from Guntersville Lake to below the proposed

Brown's Ferry Nuclear Plant is the area under intensive study for physical, chemical, and biological factors. Efforts are continuing to interest the Department of the Interior in sponsoring this study.

As a direct result of these studies, cooperation has been extended to the Facilities Office and the Environmental Health Service of the MSFC Medical Center. Assistance is in the form of analysis of fluid effluent from the center and facilities design to treat this effluent. Since this discharge is into Indian Creek, which flows through a wildlife refuge before reaching the river, the discharge can affect aquatic organisms and ecological conditions over an extended area. By determining the effluent contents, results should indicate the physical facilities necessary for the center to control its fluid discharge into natural waters.

Also as a result of these studies, assistance has been extended to the City of Huntsville in the formulation of a water pollution control ordinance.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

2.1473, FACTORS INFLUENCING THE PRODUCTION OF PLANKTONIC AND BENTHIC PLANTS

G.E. SMITH, U.S. Tennessee Valley Auth., Div. of Environ. Res. & Dev., *Muscle Shoals, Alabama* 35660

The role of factors that control rates of growth and total standing crop of both planktonic and benthic plants will be studied in streams and reservoirs. These studies will evaluate effects of the following factors in growth rates under field and, in some cases, laboratory conditions: (a) various nutrient levels; (b) interaction of communities due to excretion of extracellular metabolites or competition for nutrients; (c) the source of nutrients in streams and reservoirs whether from land areas having various forms of vegetal cover, or from waste discharges; (d) substrate types; (e) light penetration; (f) reservoir operation and hydraulic flow characteristics; and (g) other physical and chemical characteristics of the flowing or impounded waters. A prediction equation that will include and define the relative importance of the significant factors will be developed, based on a multivariate analysis of the data.

SUPPORTED BY U.S. Tennessee Valley Auth.

2.1474, EFFECTS OF LARGE SCALE FOREST FIRES ON WATER QUALITY IN THE INTERIOR OF ALASKA

F.B. LOTSPEICH, U.S. Dept. of the Interior, Federal Water Quality Admin., *College, Alaska* 99701

The purpose of this project is to evaluate the significance of large scale forest fires as polluting agents in Alaska's interior. Evidence from work in other states suggests that soil properties change as a result of burning. Little or no work is available on the effect of these changes in soil properties on water chemistry of streams draining burned watersheds. Moreover, the effects of burning on stream biota, resulting from aberrations in water chemistry, has received little attention. This project is designed to compare soil chemistry to water quality of streams draining these watersheds. Species composition of stream biota will be related to water chemistry to provide information on the significance of burning to biological changes caused by forest fires.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1475, BIOLOGICAL EFFECTS OF HEAVY METAL POLLUTION

D.K. BUTTON, Univ. of Alaska, Inst. of Marine Sciences, *College, Alaska* 99735

Our thesis is that heavy metals combined with microorganisms effecting their affinity for substrates. This phenomenon is significant only when the buffer and chelating capacity of the medium is very low such as in natural water systems (rivers, lakes, and the ocean). This steady state level of biooxidizable organic material is a function of heavy metal levels. We find that phosphate limited cultures of a marine yeast and a marine bacterium in continuous culture are adversely effected by 10 to minus the 7th power M Cu ion. We have described the phosphate incorporation kinetics and are proceeding to describe the phosphate-heavy metal-organism relationship.

Work is being performed at the University of Alaska and the Department of Biophysics, University of Colorado Medical Center.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1476, ECOLOGY AND NITROGEN CYCLE IN A MARINE PLANT COMMUNITY

J.J. GOERING, Univ. of Alaska, Inst. of Marine Sciences, *College, Alaska* 99735

The physiological ecology of eelgrass (Zostera marina) communities will be examined in concurrence with the dynamics of the nitrogen cycle in a lagoon on the Bering Sea coast of Alaska. A comparison of natural conditions will be made with an area receiving untreated sewage. This will include an examination of the relationship between the primary producers and nitrogen cycle, with emphasis on the role played by nitrogen in the total productivity of the community. Also to be included is the control of the environment on the growth and morphology of the dominant primary producer, eelgrass. The contribution of organic matter, particulate and dissolved, from the eelgrass community to near-shore oceanic food webs will also be investigated.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1477, POSSIBLE EFFECTS OF CRUDE OIL ON AQUATIC ORGANISMS

J.E. MORROW, Univ. of Alaska, School of Biological Sciences, *College, Alaska* 99701

Normal, unexposed fishes will be analyzed to determine normal ranges of variation. Gills, stomach, liver, intestine, pancreas, spleen and kidney will be examined histologically. Blood parameters, Na plus, Cl minus, K plus, CO2, O2, Hb, serum proteins and lipids and pH will be measured. During experiments, same parameters will be examined on controls and experimental animals.

Three series of experiments are planned, in salt water, since the major pollution effects can be expected in the marine environment, all replicated at 3 temperatures. Temperatures will approximate maximum, minimum and mean to be encountered in Central Alaskan fisheries areas. Experiments are as follows: Series I. Fish will be exposed to crude oil, various concentrations, for periods up to 30 days. Their reactions will be observed and measured. Series II. Fish will be passed through a film of crude oil to expose respiratory organs to oil. Respiratory organs and reactions of animals will be examined in detail. Series III. Fishes will be fed controlled amounts of oil to determine whether ingestion of oil has deleterious effects on animals, and if so, how effects are produced.

Most of the work will be done in the Alaska Water Laboratory, FWQA. Histology to be done in Department of Biological Sciences, University of Alaska, computer work at the University of Alaska computer center.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1478, RELATIONSHIPS BETWEEN LOGGING ACTIVITIES AND SALMON PRODUCTION

K. DURLEY, State Dept. of Fish & Game, *Juneau, Alaska* 99801

Objectives of this phase are to complement and extend the presently established joint monitoring effort of the U. S. Forest Service and the Alaska Department of Fish and Game in order to determine if stream changes due to logging and other causes occur and to what extent changes effect the potential of these streams to produce salmon fry.

The following characteristics are being monitored on three important salmon producing streams in Southeastern Alaska: (1) Composition of streambed spawning areas; (2) stream flow and water temperature; (3) stream channel configuration and amount and kind of debris in the stream; (4) classification of soil types in the watershed; (5) sources of sediment; (6) production of salmon fry and survival and (7) assessment of adult salmon escapement.

The studies to date have been a cooperative venture between the U.S. Forest Service and the Alaska Department of Fish and Game, with each agency responsible for part of the work. The

study is primarily concerned with establishing a base for management action to assure that no single resource is being utilized for the detriment of another resource.

Procedures for characteristics monitored by the Alaska Department of Fish and Game are described in the Fisheries Research Institute, University of Washington, Field Manual, dated 17 February 1964.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1479, MONITORING THE EFFECTS OF LAND USE ON SALMON PRODUCTION

T.C. HOFFMAN, State Div. of Comm. Fisheries, *Juneau, Alaska* 99801

Objectives: To complement and extend the presently established joint monitoring effort of the U.S. Forest Service and the Alaska Department of Fish and Game in order to determine if stream changes due to logging and other causes occurred and to what extent these changes affected the potential of these streams to produce salmon fry.

Characteristics Monitored: (1) Composition of streambed spawning areas. (2) Streamflow and water temperature. (3) Stream channel configuration and amount and kind of debris in the stream. (4) Classification of soil types in the watershed. (5) Sources of sediment. (6) Production of salmon fry and survival. (7) Assessment of adult salmon escapement.

Characteristics studied prior and subsequent to land use and observations taken yearly.

The studies to date have been a cooperative venture between the U.S. Forest Service and the Alaska Department of Fish and Game with each agency responsible for part of the work. The study is primarily to establish a base for management action and is presently being conducted in one important salmon producer in Southeastern Alaska and will be extended to three with special reference to logging and road building.

Procedures: For these characteristics monitored by the Alaska Department of Fish and Game as described in Fisheries Research Institute, University of Washington Field Manual dated 17 February 1964.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.1480, LIMNOLOGICAL EFFECTS OF ORGANIC WATERSHED LITTER

W.J. MCCONNELL, Univ. of Arizona, Arizona Coop. Fishery Unit, *Tucson, Arizona* 85721

Previous work under this project has shown that phenolics derived from litter may occasionally reach concentrations in excess of 10 mg/liter in some natural waters. Considering the documented physiological effects on mammals of many phenolics, one may postulate that fish and aquatic invertebrates are affected by litter phenolics. Current project emphasis is on long term bioassays of fish and invertebrates to detect sub-acute effects on survival, growth, and larval development. Classes of compounds being tested are hydrolyzable tanning, flavonoid tannins, hydroxy-benzenes, hydroxy benzoic acids, flavonoids, vanillin-like compounds, and hydroxy-cinnamic acids.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1481, IMPOUNDMENT EFFECTS ON WATER QUALITY AS REFLECTED IN PARASITISM OF RESERVOIR BASSES

D.A. BECKER, Univ. of Arkansas, Water Resources Research Ctr., *Fayetteville, Arkansas* 72701

The proposed study is the first pre-impoundment through early impoundment investigation of this nature to be conducted in the United States.

Field investigations will employ electrical shocking gear for the live collections of the black basses Micropterus dolomieui Lacepede, M. punctulatus (Rafinesque), and M. salmonides (Lacepede).

Basses will be examined in the laboratory for helminth and copepod parasites in an effort to follow the quantitative and qualitative dispersions and fluctuations of these parasites as the water quality is effected by the water level fluctuations from a river to a reservoir environment. Standard and total length, weight, and scale samples will be obtained to ascertain the effect of parasitism on the aging and growth rates of basses which may help explain why sport fishing declines after several years in recently impounded reservoirs effecting the recreational economy of the municipalities surrounding reservoirs. Parasitism will be related to the whole food chain in an attempt to establish another parameter for water quality.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1482, EFFECTS OF WATER DIVERSION ON BIOTA AND WATER QUALITY IN THE STATE OF ARKANSAS

R.V. KILAMBI, Univ. of Arkansas, Water Resources Research Ctr., *Fayetteville, Arkansas* 72701

The proposed study is to evaluate biological characteristics of fish in Arkansas Reservoirs and the King's River, the latter serving as an unaltered environment. The emphasis is on the population structure in relation to the environment with special reference to meristic and morphometric characters, age and sex composition, rate of growth, fecundity, and interaction between populations or species and their environment. Laboratory experiments will be planned to study the effects of temperature on hatching and survival of eggs, critical period in the development of eggs, and the fixation of the meristic characters.

It is also planned to tabulate and correlate plankton data with physical and chemical variants collected from five small Arkansas impoundments over a period of 28 years. Emphasis will be placed on seasonal cycles of plankton species characteristics of these environments, their possible use as indices of trophic levels, and the succession of species along with physical chemical change in two small artificial lakes over 28 years. Laboratory experiments will be performed to determine effects of controlled physical and chemical factors on resident plankters and the results compared with field data.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1483, BUILD-UP OF MINERAL CONTENT IN LAKE DARDANELLE AND THE EFFECT ON ZOOPLANKTON

T.N. PALKO, Arkansas Polytechnic College, Water Resources Research Ctr., *Russellville, Arkansas* 72801

This project is concerned with pollution and build-up of mineral concentrations in Lake Dardanelle Reservoir, principally as a result of turkey farming ranges in the watershed area of Lake Dardanelle and their effects on zooplankton populations.

The study will cover a 3 year period; starting date is June 1, 1970, and completion is November 1, 1972. Testing is to be conducted during the months of June, July, August, and September of each year.

Lake Dardanelle is a large, artificial lake created by the damming of the Arkansas River as a part of the Arkansas River Navigation Project. It is located in North Central Arkansas near Russellville, Arkansas.

Objectives are to include: chemical analysis; quantitative and quantitative zooplankton counts on a weekly basis. These weekly tests are to be conducted 1. on several tributaries near locations of turkey ranges; 2. at the mouths of said tributaries as they enter the lake; and 3. out in the lake to determine dilution rates.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1484, ICHTHYOFAUNAL DIVERSIFICATION AND DISTRIBUTION IN THE BIG CREEK WATERSHED, CRAIGHEAD AND GREENE COUNTIES, ARKANSAS

G.L. HARP, Arkansas State University, Graduate School, *State University, Arkansas* 72467

Big Creek is a relatively small deltaic stream in northeastern Arkansas, in an area of intense cultivation. Recently it has been dredged in the interest of flood control. Lost Creek and Mud Creek are the major tributaries of Big Creek and collectively drain the Big Creek watershed. The streams had relatively low alkalinity, moderate CO2 and adequate O2 values, and relatively high turbidity. Channeling of Big Creek and Lost Creek had effec-

tively destroyed distinct pool-riffle biocies and reduced the number of acceptable spawning sites. Lost Creek also receives effluent from residential dwellings, a secondary treatment sewage plant, and a meat rendering plant. Mud Creek, in the absence of channeling and deleterious effects of effluents, provided a relatively greater diversity of habitat than did Big or Lost Creeks.

A total of 21 species were collected. Big Creek supported 17 species, Mud and Lost Creeks supported 14 and 11 species, respectively. Five of the 11 species in Lost Creek are characteristic of streams with much organic debris and were not collected in numbers at any other station in the watershed.

Of the 2,209 fishes collected, Notropis umbratilis, Fundulus olivaceous, and Lepomis cyanellus made up 63% of the total and were taken at all stations. Their relative abundance is supported by their ability to withstand high turbidity and limited competition due to depth effect.

Limited species including Ictalurus natalis, Aphredoderus sayanus, and Etheostoma gracile in Mud Creek; Dorosoma cepedianum in Lost Creek; and the headwater species Semotilus atromaculatus in Big and Mud Creeks.

SUPPORTED BY Arkansas State University

2.1485, ENVIRONMENTAL STUDY OF PORT PHILLIP BAY

UNKNOWN, Australian Dept. of Fish. Wlf., *Melbourne, Victoria, Australia*

To determine what adverse effects, if any, are likely to result from the disposal to the bay of effluent from the Board's South Eastern Purification Plant.

Background study completed, coarse grid mathematical 'hydraulic - water quality' model of bay developed.

SUPPORTED BY Australian National University

2.1486, TO STUDY THE ENVIRONMENTAL FACTORS AFFECTING REPRODUCTION IN OSPREYS OF FLATHEAD LAKE, MONTANA

J.R. KOPLIN, Humboldt State College, Graduate School, *Arcata, California* 95521

Special techniques. Continue obtaining measurements on reproductive performance of ospreys on Flathead Lake; critically assess the effect of food supply on reproductive performance of ospreys; collect and analyze addled eggs for pesticide residues and shellthickness; try to determine cause of losses of eggs or chicks.

SUPPORTED BY National Geographic Society

2.1487, TURBIDITY EFFECTS ON MARINE ANIMALS RESULTING FROM MARINE MINING

F.A. NUDI, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Belvedere, California* 94920

Objective: To study the effects of suspended inorganic sedimentary materials on selected marine animals. This is a cooperative study with the Bureau of Mines, Marine Minerals Technology Center, Tiburon, Caifornia. The study is an integral part of the Bureau of Mines effort to define the environmental problems that may be triggered as future offshore mining accelerates. This study is expected to take from 2 to 5 years to complete and will be conducted in temporary wet laboratory facilities located at the University of California Laboratory, Bodega Bay, California.

Procedure: 1) Development of laboratory facilities to provide a wide range of turbidity for flowing water aquaria tests. 2) Tests will be conducted with various types of inorganic clays of various grain sizes on selected marine organisms. 3) Physical parameters, such as dissolved oxygen, temperature, pH, salinity and turbidity, will be continuously monitored. 4) Parameters to be examined on the test animals as related to various turbidity levels will be weight changes, growth, time to mortality and possible respiration rate and some tissue analysis. 5) Analytical data and conlusions will be summarized in a final report for publication.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1488, FLOOD AND SEDIMENT REDUCTION IN THE CONIFEROUS TIMBER ZONE IN CALIFORNIA

R.R. ZIEMER, U.S. Dept. of Agriculture, Pac. Sw. For. & Rg. Expt. Sta., *Berkeley, California* (PSW1603)

OBJECTIVE: Develop management methods that will minimize local floods, erosion and sedimentation, maintain water quality, and improve timing of streamflow; and to develop methods for predicting the effects of forest and land management practices upon sedimentation and streamflow.

APPROACH: Studies of gravitational mass movement will continue; resurveys of inclinometer holes will determine rate and location of surface and subsurface creep; and aerial photo comparisons will point out causes of landslides. Continue to study the effects of logging on streamflow, sedimentation, and fish habitat, and current studies will relate soil moisture to logging effects and to moisture storage opportunities for flood abatement.

PROGRESS: In California's north coast, landslides are frequently the major cost hazard facing the construction, maintenance, and satisfactory performance of roads. The direct annual costs of road maintenance and postconstruction stabilization efforts, necessitated by landslides, alone often amount to a large percentage of the initial construction costs. The indirect costs of landslides are of greater magnitude and persist longer than the more obvious direct costs. Not included in the estimate is the long-term erosion and sedimentation damage caused by road-triggered landslides. Such disturbances to the normal erosion cycle are not limited to the boundaries, locality, mechanism, or time of the original slide. Landslides reaching stream channels often force streams against the opposing bank, resulting in their oversteepening and the triggering of new slides. Riprap placed in channels to protect the unstable toe of a slide may bring about the same result. The movement of C from the old needles to the roots, and later to the new needles, was measured in 2-year-old ponderosa pine seedlings. The seedlings were in one of three growth stages at the time of feeding CO_2: 9 days before spring bud break with no root activity; 7 days before spring bud break with high root activity; and 7 days after spring bud break with moderate root activity.

2.1489, NAVY ENVIRONMENT CONTROL OF ENVIRONMENTAL FACTORS AFFECTING NAVAL PERSONNEL AND MATERIALS

N.A. VEDROS, Univ. of California, School of Public Health, *Berkeley, California* 94720 (N00014-69-A-0200-1001)

Technical Objective: The effective use of the ocean as a working environment requires a thorough knowledge of its microbial activity. This is especially true when consideration is given to the biological fouling problems which confront the Navy. This effort will assist in developing methods to control fouling, corrosion, and deterioration.

SUPPORTED BY U.S. Dept. of Defense - Navy

2.1490, BIOLOGICAL METHODS OF SLUDGE DEWATERING

F.R. BOWERMAN, Aerojet General Corporation, *El Monte, California* 91734

A twelve-month program is proposed to investigate the poly-beta hydroxybutyric acid depolymerase activity of various microorganisms and to prepare extracts displaying such activity. These enzyme preparations would be applied to typical microbial sludges obtained from activated sludge plants to determine the effect on water retention of the sludge. Satisfactory demonstration of a beneficial effect would lead to screening of microorganisms for an extracellular source of the enzyme. Factors that affect enzyme production and stability will also be investigated.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1491, RADIOECOLOGICAL STUDY OF THE HUMBOLDT BAY MARINE ENVIRONMENT - DEVELOPMENT OF A MODEL
R.E. HEFT, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

The underlying objective is to develop a capability for predicting, for any arbitrary site at which oceanographic parameters are known, the amounts of individual radionuclides that will be taken up by specific marine organisms, given the amount and frequency of radionuclide release. This objective is best considered as involving two separate problems: (1) transport objective, given an arbitrary site for which oceanographic data are known, to predict for any given location and time after release the amounts of individual radionuclides that would be present (a) in solution, (b) attached to suspended silt, (c) in plankton, and (d) attached to settled silt; (2) uptake objective: given a pool containing an ecologically balanced group of marine organisms and with known amounts of stable element and individual radionuclides in (a), (b),(c) and (d) as listed above, predict the amounts and the manner in which the individual radionuclides will be taken up by each species of marine organism.

SUPPORTED BY U.S. Atomic Energy Commission

2.1492, BACTERIOLOGY OF BIODEGRADABLE SURFACTANTS
D.A. ANDERSON, Calif. State College, Graduate School, *Los Angeles, California* 90032

This investigation is concerned with responses of typical Gram negative and Gram positive bacteria when grown in the presence of various molecular varieties of syndets. Representative anionic or nonionic biodegradable surfactants used include: dodecylbenzene sulfonates (linear), ethoxylated alcohols, ethoxylated alkyl phenols, alkyl ether sulfates, taurates, and ricinoleates. Gram negative bacteria used are primarily strains of Escherichia coli and Pseudomonas spp. Gram positive forms are mostly Staphylococcus spp. and Bacillus spp.

Gram negatives typically exhibited a temporary inhibition of growth in the presence of certain surfactants followed by rapid proliferation with profuse production of a pervasive slime. Roles of cell membrane leakage, extracellular synthesis of slime, or both, are being studied. Chemical nature of the slime is being investigated. An apparent blocking of phage receptor sites by slime has been observed and is under study. Attention is also being given to effects of the slime on pili and flagella.

With Gram positive bacteria, quite different growth responses have been noted. Non-sporing or vegetative cells of sporeformers appear to be uniformly rendered nonviable. Lethal damage to cell membranes or cell walls is under study. In addition to the usual chemical and physical procedures, extensive use is being made of electron microscopy.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1493, NAVY ENVIRONMENT - AVOIDANCE AND CONTROL OF THE EFFECTS ON MEN & MARINE LIFE OF TOXIC RED TIDES INITIATED BY LOCAL POLLUTION OF THE SEA
B.C. ABBOTT, Univ. of Southern California, School of Letters, *Los Angeles, California* 90007 (N00014-67-A-0269-0017)

Technical Objective: The phenomenon known as red tide, in which there is a sudden rapid multiplication of marine microorganisms leading to tinting of the water, the production of toxin which may be lethal to marine life and a health hazard to man, is the subject of this investigation. In the laboratory, the investigator has been able to reproduce the essential effects when certain growth stimulants are added to quiescent cultures of the organisms. The question arises as to what provides the stimulus in nature. There is a high probability that the materials appear in triggering concentrations in localized areas as pollutants, and the question then becomes what they are and what they do. The possibility that effluents from underwater habitats or from ships at anchor could trigger a red tide or related phenomenon must be investigated since such a localized production of incapacitating neurotoxin could kill or incapacitate Naval personnel and since, even in less extreme circumstances, the effects on local ecology, food supply or living environment could result in embarrassment to the Navy if the danger is not recognized and controlled.

SUPPORTED BY U.S. Dept. of Defense - Navy

2.1494, RESEARCH IN LIMNOLOGY - INTERRELATIONS OF HYDROLOGY AND AQUATIC ECOLOGY
K.V. SLACK, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

Biological processes are among the major controls on the quality of natural waters. Organic control on solute concentration occurs in two ways: substances enter or leave solution either as the results of changed physico-chemical conditions in the water, or as the results of physiological processes within living cells or at their boundaries.

The work is divisible into three related phases:

Phase 1. Stream Limnology. a. The effect of stream-bed algae on water quality will be studied in flowing-water cultures (laboratory streams) in which temperature, light intensity, flow rate, water composition and algae species can be controlled. The first problem being studied is the uptake and release of combined inorganic nitrogen by mixed populations of stream algae. b. Investigation of the physical, chemical and biological properties of different types of natural streams will continue. The emphasis will be on the interrelations of the biota and water quality.

Phase 2. Lake and reservoir limnology. a. Effects of reservoir destratification. The hydrologic effects of destratification will be studied experimentally by isolating portions of a stratified reservoir in polyethylene cylinders extending from the water surface to the bottom. b. Environmental controls on phytoplankton populations. This will combine the results of field investigation with controlled laboratory studies of static and flowing cultures of nuisance species of algae.

Phase 3. Ecological role of natural organic compounds in water. The particular emphasis will be on the identification of organic compounds which influence biological activity in natural waters.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.1495, MARINE WASTE DISPOSAL AND SEA URCHIN ECOLOGY
W.J. NORTH, Calif. Inst. of Technology, Graduate School, *Pasadena, California* 91109

The primary objectives are to establish whether discharged sewage effluent aids survival of urchin populations and if so, would the effect be lessened by altering sewage treatment. Our hypothesis, developed during the first two years of this study, postulates that dissolved organic substances from sewage effluents make significant contributions to urchin nutrition. The dissolved substances might even sustain urchin populations completely after their natural food resources, the valuable kelp forests, have disappeared. Our measurements of dissolved free amino acids (DFAA) indicate concentrations near outfalls may be twice or more above background. At such concentrations, one common urchin (Strongylocentrotus purpuratus) can absorb DFAA across the body wall at a rate sufficient to supply 50% of the daily maintenance requirement. Physiological evaluations indicate that urchin populations at outfall stations are nutritionally in good condition, although gametogenesis may be altered.

2.1496, EFFECTS OF SELECTIVE LOGGING ON STREAMBED SEDIMENTATION AND WATER TEMPERATURES IN SOUTH FORK YAGER CREEK, HUMBOLDT CO., CALIF
J.W. BURNS, State Dept. of Fish & Game, *Sacramento, California* 95819

P.S. Objectives: To determine and evaluate the effects of selective logging on stream habitat and juvenile salmonid populations in California's small coastal streams.

Job Objectives: 1. To measure streambed riffle size composition, percentage pool length, and stream temperatures; 2. to compare these results with values obtained in prelogging surveys and with upstream, experimental control values; and 3. to determine the effects selective logging has had on streambed sedimentation, pool periodicity and water temperatures.

Procedures: Streambed samples are obtained with a stainless steel cylinder similar to the one described by McNeil and Ahnell (1964). Single samples are taken from the center of the stream near the head of a riffle. The lower tube of the sampler is worked into the streambed to a depth of 6 inches, the contents dug by hand and lifted into a bucket. After removing the large materials, water within the tube is agitated, settling the remaining small materials into suspension. A plunger is pushed into the tube and a cork inserted in the plunger. Turning the plunger handle expands the O ring rubber seal allowing no water or sediment to spill while removing the sampler from the streambed. Ten samples are taken at equidistant points within each of the two study units during the August survey. Standard Tyler screens with 26.67mm, 3.327-mm, and 0.833-mm openings are used to separate the samples into four size classes, three of which are retained by the respective sieves while the remaining class passes through the 0.833- mm screen. Volumes for those classes are measured by water displacement in 4,000-ml graduated cylinders. The fraction passing the 0.833-mm screen is allowed to settle for 10 minutes before measuring the amount of solids settling to the bottom of the cylinder. Results are expressed as the mean percentage.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1497, EFFECTS OF ALTERNATE BLOCK CUTTING ON STREAMBED SEDIMENTATION & WATER TEMPERATURES IN BUMMER LAKE CREEK, DEL NORTE COUNTY, CALIFORNIA

J.W. BURNS, State Dept. of Fish & Game, *Sacramento, California* 95819

P.S.Objectives: To determine and evaluate the effects of alternate block cut logging on stream habitat and salmonids in California's small coastal streams.

Job Objectives: 1. To measure streambed riffle size composition, percentage pool length and stream temperatures in Bummer Lake Creek; 2. To compare these results with values obtained in prelogging surveys and with Godwood Creek, Humboldt County (experimental control) values; and 3. To determine the effects of alternate block cut logging on streambed sedimentation, pool periodicity and water temperatures.

Procedures: Streambed samples are obtained with a stainless steel cylinder similar to the one described by McNeil and Ahnell (1964). Single samples are taken from the center of the stream near the head of a riffle.

Twenty-one samples are taken at equidistant points within each stream during each survey. Standard Tyler screens are used to separate the samples into four size classes, three of which are retained by the respective sieves, while the remaining class passes through the 0.833-mm screen. Volumes for those classes retained are measured by water displacement.

Results are expressed as the mean percentage of the total sample volume passing each sieve. Sample volumes are assumed equivalent so that individual samples can be transformed into sediment size class percentages and then averaged.

Stream width and average depth are measured on transects at permanent stations. Percentage pool length is determined by measuring pool length in a 100-ft section immediately downstream from each 250-ft station and 50 ft downstream from every 100-ft station. Stream discharge is measured at the mouth of each stream. Mean stream width is determined by averaging the width measurements, while average stream depth is determined by weighting each average station depth by the width at that station. Bummer Lake Creek data are compared with prelogging and Godwood Creek data to ascertain the effects of alternate block cutting on streambed composition and living space. (Text Abridged)

2.1498, THERMAL POLLUTION AND SOCIAL BEHAVIOR OF FISHES

J.A. TODD, San Diego State University, School of Liberal Arts, *San Diego, California* 92115 (AT)

The sublethal effects of thermal pollution have been little studied but it appears that they may be more significant in reducing or eliminating fish populations than the occasional heat-induced mortality. A recent pilot study carried out by the junior investigator indicates that at sublethal high temperatures social behavior of fishes may be drastically altered. It is proposed to futher evaluate the effects on social behavior of high sublethal temperatures for a temperature- tolerant fresh water fish, the yellow bullhead, Ictalurus natalis, and a sensitive species, the mottled sculpin, Cottus bairdi. Similar observations will be made on a common marine species, the mussel blenny, Hyosoblennius jenkinsi. Our principal objectives are to determine whether at high sublethal temperatures the social behavior of the test species is quantitatively or qualitatively altered and to observe the effects of such changes on the population structure of these species.

All laboratory experiments will be carried out first at normal summer temperatures for the species being studied, then repeated at temperature increments of 1 degree C until the lethal point is reached. Three aspects of social behavior will be observed under this temperature regime: interaction between individuals, community structure and recognition of individuals by chemosensory means.

Interactions between individuals will be studied by confining pairs of fish together and making daily ethological recordings. The resulting data will be analyzed for thermally induced changes in level of aggression, relative dominance and territorial behavior.

Community structure will be studied by setting up communities of three or more fish in large aquaria and making daily ethological recordings at normal temperatures until it is judged that the fish have established a stable relationship with one another. Then the temperature will be gradually raised and further ethological recordings made as described above. Visual observation will be supplemented by still and cine photography in endeavoring to detect possible breakdowns in community structure and other changes in social behavior.

If significant changes in community structure are observed, the observations will be repeated at selected high temperatures with the addition of a strange fish to each test community. The reactions of the resident fish will be recorded and compared with the social interactions of similar communities.

2.1499, EFFECTS OF NUTRIENTS AND POLLUTANTS ON THE GROWTH OF MARINE PHYTOPLANKTON

W.A. THOMAS, Univ. of California, Inst. of Marine Resources, *San Diego, California* 92038

This grant continues support for studies on the effects of nutrients on the growth of marine phytoplankton, and initiates support for studies of the efects of pollutants on these organisms. The nutrient studies will concentrate on the effects of limiting concentrations of inorganic nitrogen on tropical Pacific algae, and the effect of light and temperature on the nutrient requirements of these forms. Major emphasis will also be placed on development of a fluorescence technique for measuring cell densities in test tube cultures. Such a technique would be far less time consuming than direct cell counts, and its use would permit efficient examination of phytoplankton growth rates under a great variety of natural and pollutant effected conditions. Initial experiments suggest that this technique is feasible. This grant will support studies to test it further.

2.1500, THE EFFECT OF SCHOOL WATER FLUORIDATION ON DENTAL CARIES

S.B. HEIFETZ, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Natl. Insts. of Health, *San Francisco, California*

2. WATER QUALITY

Purpose: To determine the relative decay preventive benefits derived by children who, when at home, drink water that is essentially devoid of fluoride but, when at school, consume fluoridated water.

Subject: Children in grades 1-12 who have continuously attended the study school since the time they were eight years of age or younger. Approximately 800 children in Seagrove, North Carolina were examined on the baseline.

Methods: Fluorides were added to the school water supply in Seagrove, North Carolina at 6.3 ppm, seven times the level considered optimal for community fluoridation in the same geographic area. A higher than optimum concentration for community fluoridation in the geographic area is used in an attempt to duplicate the total fluoride intake of children who drink optimally fluoridated water on a full-time basis. Prior to the installation of fluoridation equipment, dental examinations using the DMF tooth and surface index were conducted to determine initial caries prevalence rates. Follow-up examinations, including an assessment of the extent of fluorosis, if any, will be conducted at four-year intervals.

Findings to date, if any: Interim reports will be prepared after 4 and 8 years of study. The study will continue for 13 years.

2.1501. ABUNDANCE AND COMPOSITION OF DEEP AND SHALLOW WATER MACROPLANKTON AND LITTORAL FISH POPULATIONS IN AND ABOUT THE SANTA BARBARA CHANNEL

A.W. EBELING, Univ. of California, School of Letters, *Santa Barbara, California* 93106

From February through August, 1969 inshore fish communities were sampled with a 16-foot semi-balloon trawl in deep and shallow water habitats off Santa Barbara, California. Fifty-eight collections sampled three communities: mud bottom at 150-200 feet, sandy bottom on the seaward edge of a kelp bed at 30-45 feet, and sandy bottom inside the kelp bed at 12-18 feet. To assess possible changes in fish communities after a January oil spill, these collections were compared with others from 1967 and from an unpolluted area to the south. The deep community had changed little between years or localities; the same fishes predominated in similar abundances: flatfishes, young rock fishes, a sculpin, midshipman fish, and surf perch. Although the shallow communities fluctuated more than the deep, differences, such as the shallow occurrences of deep species, may be attributable to the vagaries of upwelling. Stations in the southern unpolluted area were less productive than those in Santa Barbara.

Offshore plankton collections trawled from the General Motors Research Vessel SWAN were similar in composition and abundance to others made during the same month, March, in three previous years. Breeding was apparently normal; collections contained the fish larvae characteristic of the area. We have noted, however, the disappearance after the oil spill and subsequent gradual reappearance of a common mysid shrimp that usually abounds on the surface of the kelp.

SUPPORTED BY: U.S. Environ. Protect. Agency - O.O.W.P.

2.1502. A STUDY OF THE INITIAL EFFECTS OF THE SANTA BARBARA OIL SPILL

M. NEUSHUL, Univ. of California, Graduate School, *Santa Barbara, California* 93106

The study deals with the effect of a flow of oil that began on January 28, 1969, and still flows from the ocean floor near an offshore oil platform. By February 8, 1969, 4,508 metric tons of pollutant oil was deposited on 87.7 kilometers of coastline. Heavy biological damage occurred in intertidal surf grass communities and among barnacle populations. The damage attributable directly to the oil was obscured by heavy storm damage that took place just prior and during the oil spill. The potential long-term biological effects of continuing oil pollution are discussed. (Work completed Sept. 1969).

2.1504. ECOLOGY OF COLORADO MOLLUSKS

R.W. PENNAK, Univ. of Colorado, Graduate School, *Boulder, Colorado* 80302

Changes in distribution and ecology of mollusks in Colorado, especially during the past 60 years, as influenced by pollution. Shell morphology as determined by water chemistry.

SUPPORTED BY: University of Colorado

2.1505. BOTANICAL RESEARCH - ENVIRONMENTAL GEOCHEMISTRY IN RELATION TO HEALTH AND DISEASE

H.L. CANNON, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

States to which project pertains: U.S.

A preliminary evaluation by an interdisciplinary group of the possible effects of the geochemistry of rocks, soil, plants, and water on patterns and incidence of human and animal disease has resulted in the establishment of an NRC Subcommittee under the chairmanship of H. Cannon to establish the state-of-the-art through symposia and workshops. Probably the greatest gaps in our knowledge involve the availability and interaction of metals at each step through the food chain, and the acquisition of data concerning background and optimum levels of metals in soil, water and plants. Only with such basic data can the effects of treatment and of pollution be properly evaluated. A symposium chaired by H. Cannon and H.C. Hopps, M.D., on 'Metals of the Geochemical Environment--Health and Disease' was presented at the AAAS meetings in Chicago. A New York Acad. conference is planned for 1971 and a workshop in 1972.

Cannon will collate survey material on Pb in plant-soil relationships for a professional paper by several authors on lead in the environment.

SUPPORTED BY: U.S. Dept. of Interior - Geological Survey

2.1506. RESEARCH AND BASIC DATA ON THERMAL POLLUTION

G.E. HARBECK, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

This work, initiated in FY'69, involves research into some of the theoretical aspects of heat transfer and dissipation when heated water is discharged to rivers. Of primary interest will be the relationships among the eddy-transfer coefficients, or diffusivities, of heat, momentum, and water vapor when the atmospheric lapse rate is non- adiabatic.

In addition to the research, certain basic data will be collected and published that will be immediately helpful to both plant designers and researchers. The data would include flow measurements of temperature profiles, and velocity distribution under controlled conditions on 10 to 12 streams representing a wide range of flow conditions and a variety of climatic and weather conditions. In addition, various pertinent meteorological parameters would be measured, air temperature, humidity, and wind speed.

2.1507. LARGE IMPOUNDMENTS - PUEBLO RESERVOIR

D.A. HOFFMAN, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

The Bureau of Reclamation has constructed numerous large impoundments which are characterized by being deep and long.

located in an arid climate, and relatively unknown from the standpoint of limnological data. The lack of information is perhaps the greatest void in water data on these reservoirs. Pueblo Reservoir, located in the foothills of the Central Rocky Mountains, typifies a large terminal reservoir of a project which delivers water for irrigation, industrial, and municipal purposes. As such, its climatic, operational, and functional factors make it an ideal choice for a general study. This program will investigate the effect of a large reservoir and its limnological characteristic upon downstream water quality. Climatic, limnological and hydrological data will be collected for use in predicting future conditions in Pueblo Reservoir as well as determining effects of construction operations on downstream aquatic life, downstream community water supply, and water quality in a downstream reservoir.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.1508, ECOLOGICAL IMPACTS OF RECLAMATION PROJECTS
D.A. HOFFMAN, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

The construction and operation of water resource projects including impoundment, conveyance structures, transmission facilities, roads, building, etc. changes the ecology of the organisms in the affected area. The significance and magnitude of these changes are not known. The opportunities for enhancement or avoiding detrimental environmental effects were not known so that they could be accomplished. This study will document the ecological impact of water resource projects on a basinwide basis, and establish guidelines for construction of future projects and rehabilitation of existing ones. The results will be used to develop a similiar study for a large river basin such as the Colorado.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.1509, ECOLOGICAL AND LIMNOLOGICAL IMPACT OF THE CONSTRUCTION AND OPERATION OF PUMP-BACK STORAGE PROJECTS
D.A. HOFFMAN, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

In order to meet the growing demand for electrical energy, pump- back storage powerplants are being built in the western United States. These sites are usually in areas of high quality esthetic and environmental values. The effect of the construction and operation of these plants on the ecology and limnology of rivers and lakes is relatively unknown. One such plant will be the Mt. Elbert pump-back plant on Twin Lakes Reservoir. This reservoir contains one of the highest quality Lake Trout fisheries in the western United States. It is not known what the effect of the Mt. Elbert plant will be. The study will determine (1) the ecological requirements of the Lake Trout, (2) the effect of the pump-back operation on the heat budget of the reservoir, (3) the relationship between resuspension of heavy metals (from mine drainage) from the bottom muds back into the water ecosystem, (4) the circulation patterns in the reservoir due to the pump-back operation, (5) what enhancement opportunities are possible, (6) identify possible detrimental effects, and (7) chemical and physical limnology. Study will follow from preconstruction to full operation.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.1510, STANDARDS AND CRITERIA - EFFECT OF TURBIDITY
P.R. TRAMUTT, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

In order to establish water quality standards and criteria, it is necessary to know the requirements of the biota, materials, and users of the water. Specific studies will be made to better define reasonable standards for water quality factors of particular interest to reclamation projects.

Effect of turbidity studies in the laboratory and field will be conducted to quantitatively and qualitatively measure various types of turbidity producing materials as to size, source, composition, etc., in relation to hydrologic conditions and their ultimate effect on aquatic life, irrigation structures, and transmission facilities.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.1511, MICROBIOLOGICAL INVESTIGATIONS
P.M. TURNER, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

Microorganisms occurring in water supply, storage and conveyance systems cause problems such as corrosion, deposition, plugging and fouling. Investigations are made to identify the organisms, determine their mode of action and response to their environment, and to find effective measures of control.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.1512, EFFECTS OF CHEMICAL VARIATIONS IN AQUATIC ENVIRONMENTS
W.H. EVERHART, Colorado State University, School of Forestry, *Fort Collins, Colorado* 80521

The Colorado River has already been severely altered by Man, the Little South Poudre is as close to an unaltered water as can be obtained naturally today, and Piceance Creek represents a water area naturally high in salinity. These three very different water areas provide an opportunity for obtaining basic chemical characteristics. Further, Piceance Creek would be altered by any exploitation of the oil shale in the area. Year round studies of these water supplies has provided chemical analyses with an opportunity to detect any gradients correlated with time of year or environmental conditions. Collection of background information will be phased out by April 30, 1970.

Efforts during the final year of the grant (May 1, 1970 through April 30, 1971) will be directed to acute and chronic toxicity studies of aluminum and lead. The test animals are rainbow trout. Effects of lead and aluminum will be observed on the growth, behavior, and on eggs.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1513, EFFECTS OF SODIUM NITRATE AND WATER CONTAMINANTS ON TURKEY PERFORMANCE
E.W. KIENHOLZ, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00053)

OBJECTIVE: Establish the cause of delayed growth response after broad turkeys receive drinking water containing sodium nitrate for the first four weeks of life.

APPROACH: The effect of the sodium nitrate treatment will be sought by concentrated examination of turkey carcasses. Since we have noticed a trend towards reduced testes size, gonadotrophin elaboration and metabolism will be studied in turkeys that have or have not received the sodium nitrate treatment. Efficiency of meat production will be determined, and meat characteristics will be examined. For the other phase of the experimentation, selected Colorado water samples will be compared to distilled water for growing turkey performance. The effects of biological contaminants in turkey drinking water and ways to reduce ill effects of such contamination will be studied.

PROGRESS: A study was conducted to further evaluate the effect of early administration of sodium nitrate on subsequent growth of turkeys. No significant increase was observed in this year's trial when sodium nitrate was administered orally through the water or the feed at 925 and 2050 ppm. Turkeys were grown both on range and in confinement to determine if environmental conditions played a role in the response observed in previous years. Two strains of turkeys were used to determine if a strain response could be observed. Neither environmental conditions nor strain made any difference in the response to the treatments. An additional trial is being conducted to evaluate the effect of sodium nitrate as a growth stimulant on broad breasted bronze male turkeys. Sodium nitrate was administered orally in the feed and water at levels of 925 and 2050 ppm. The birds are being grown in confinement only due to adverse weather conditions. Initial data are being evaluated at the present time.

SUPPORTED BY Colorado State Government

2.1514, WATER TEMPERATURE AS A QUALITY FACTOR IN THE USE OF STREAMS AND RESERVOIRS
J.C. WARD, Colorado State University, School of Engineering, *Fort Collins, Colorado* 80521

2. WATER QUALITY

Objectives: (1) Relate quantitatively the three parameters of the surface water sine curve to the meteorologic and hydrologic factors influencing water temperature. (2) To work out methods for the quantitative application of the water temperature sine curve to all types of lakes and reservoirs. (3) To obtain methods for predicting quantitatively the effects of thermal pollution on stream and lake water temperatures. (4) To study quantitatively the diurnal variation in stream and lake water temperature at all depths.

The laminar phenomena of surface injected heat will be studied in detail to determine the degree of insulation in both horizontal and vertical axes in providing habitat for motile and non-motile aquatic organisms. New measurements of dispersal patterns of heated waters in relation to substrate types will be accumulated.

Pre-installation studies will be continued in an area of a small river system soon to be subjected to waste waters from a thermal power station.

Heat barrier effects in a lotic environment especially as related to fishes will be a part of a continuing study.

The effects of water temperatures and ice cover on the use of reservoirs and streams by waterfowl will be studied. The effectiveness of artificial ice-preventive measures will be determined on selected reservoirs.

SUPPORTED BY: U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1515. BEHAVIOR PATTERN OF SHAD IN THE VICINITY OF A HEATED EFFLUENT DURING A NO-HEAT PERIOD

W.C. LEGGETT, Essex Marine Laboratory Inc., *Essex, Connecticut* 06426

Objectives: To use sonic tags to ascertain the migration behavior, especially migration rate, through an area of the Connecticut River with a significant heated effluent during a no-heat period.

Location: Study site will be in the vicinity of the Connecticut Yankee Atomic Power Company (CYAP) outfall at Haddam Neck on the Connecticut River.

Procedures: Shad tagged during Job 1 of this segment will be expected to pass the CYAP outfall area within 5 - 10 days of entering the river. Shore based automatic monitors (described in AFC-1) will be installed at, above and below the outfall area to determine migration rates in this area. After the major tracking effort of Job 1 is accomplished, attempts will be made to track individual fish in the outfall area in order to obtain additional patterns of migration. Data will be processed as in Job 1.

SUPPORTED BY: U.S. Dept. of Commerce - N.O.A.A.

2.1516. PHYSIOLOGY AND BEHAVIOR OF LARVAE (PHYSIOECOLOGY OF SHELLFISH PROGRAM)

H.C. DAVIS, U.S. Dept. of Commerce, Natl. Marine Fisheries Service, *Milford, Connecticut* 06460

The development of routine methods for rearing bivalve larvae has enabled us to determine the effect of various ecological factors on larvae of the American oyster, *Crassostrea virginica*, and the hard clam, *Mercenaria mercenaria*. Studies have been made of the effect of the type and quantity of food, salinity, temperature, turbidity, pH, and of various pesticides and detergents on embryonic development and on growth of the larvae of these two species. In some studies we have observed the combined effect of varying two or more of these factors simultaneously.

We are currently experimenting to determine the pH range for spawning of oysters and the effect of the pH at spawning on viability of the sperm and eggs. We are also currently studying the effect of keeping oysters at lowered salinities, during gonad development and spawning, on subsequent embryonic development and larval growth at different salinities. We expect to soon have methods developed for studying the behavior of larvae and the effect of light, gravity, temperature, salinity and currents on the behavior of larvae of different ages and sizes. Such studies are urgently needed to develop an informational basis for field work on distribution of larvae.

SUPPORTED BY: U.S. Dept. of Commerce - N.O.A.A.

2.1517. ALGAL FOODS OF SHELLFISH (MICROORGANISMS AFFECTING SHELLFISH PROGRAM)

R. UKELES, U.S. Dept. of Commerce, Natl. Marine Fisheries Service, *Milford, Connecticut* 06460

Recent interest in aquaculture as a means of increasing the world's food supply and saving commercially valuable species from extinction, has focused attention on the role of unicellular algae in the aquatic environment. The methods of shellfish culture being developed for commercial hatcheries make it necessary to devise means of raising food organisms, namely unicellular algae. We are producing large amounts of unialgal cultures for a pilot plant hatchery and also working on more efficient methods of culture, harvesting and storing algal cells. We have investigated the effects of pollutants found in the environment, as pesticides, herbicides and detergents, on algal growth. The nutritional requirements and effects of antimetabolites on growth of various species are under study, as well as physical factors important in growth, such as pH, temperature, and light.

SUPPORTED BY: U.S. Dept. of Commerce - N.O.A.A.

2.1518. COHERENT AREA RESEARCH PROGRAM IN ECOLOGY

G.E. HUTCHINSON, Yale University, Graduate School, *New Haven, Connecticut* 06520

A variety of research projects in the general area of ecology are to be carried out by advanced graduate students. Among these will be: interspecies interactions between corals and the effect on succession in a coral reef; sexual maturity and growth as influenced by dominance relationships in poecilid fishes; ecology and form of gorgonians; biogeochemical cycle of the major cations in successional stages in a tropical forest; intra- and interspecific variation of shell ornamentation in relation to habitat in a number of genera of littoral marine gastropods; hypereutrophication and pollution; and behavior ecology of surface living insects.

SUPPORTED BY: U.S. National Science Foundation.

2.1519. EXPERIMENTAL STUDIES OF AIR AND WATER INTERFACIAL INTERACTION

J.D. LIN, Univ. of Connecticut, School of Engineering, *Storrs, Connecticut* 06268

The proposed research is an experimental study of the interaction on the air-water interface to be conducted in the Hydraulic Laboratory of Civil Engineering Department by utilizing most of the existing wind tunnel and instrumentation facilities. A test section, consisting of a wind tunnel over a channel of variable depth and of sufficient fetch, will be constructed for this investigation. The transient and equilibrium surface waves generated by various turbulent wind profiles with zero pressure gradient along the tunnel will be investigated. The turbulence in the wind and possibly in the water will be measured in addition to the mean quantities and the surface wave spectrum as previously studied by other investigators. The wind generated wave theories and previous experiments under somewhat different conditions will be examined. The correlation of experimental data among the wind, waves and water should provide a basic understanding and the mechanism of dispersion, mixing and perhaps diffusion of contaminated surface water or pollutant spreading over the surface of water under the action of turbulent wind.

SUPPORTED BY: U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1520. EFFECTS OF SIMULTANEOUS VARIATIONS OF DIEL CHANGES OF TEMPERATURE, DISSOLVED OXYGEN, SALINITY & A POLLUTANT ON THE GROWTH OF WHITE PERCH

W.R. WHITWORTH, Univ. of Connecticut, School of Agriculture, *Storrs, Connecticut* 06268

The primary purpose of this work is to estimate the effects of simultaneous variations of diel changes of temperature, dissolved

oxygen, salinity and a pollutant on the growth of white perch (Morone americanus). The experimental design will be a 2 x 2 x 2 x 3 with [illegible] replications. Temperature, dissolved oxygen and salinity will each have two levels, both fluctuating on a diurnal basis, and the toxicant will have 3 levels (number of times/day will be part of the level).

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1521, ENVIRONMENTAL CONTROL SYSTEM FOR OYSTER FARMING
O.R. HARMAN, Univ. of Delaware, Agricultural Experiment Sta., *Newark, Delaware* 19711 (DEL00146-AGE)

OBJECTIVE: Design and develop and analyse a controlled environment system for the culture of oysters.

APPROACH: A system will be designed to allow temperature, water flow, and nutrient addition control in a step-wise fashion from the induction of spawning to maturation of the oyster. Throughout the process, analyses will be made of the contribution of various alternate equipment use in terms of economics and in terms of equipment contribution to pollution. In addition, where natural water sources are used, pesticide and other contaminants will be assayed.

PROGRESS: Hot, cold and ambient temperature seawater is now available in the shellfish laboratory at Lewes, Del. A 250,000 BTU per hour oil-fired heater was added to raise the temperature of incoming salt water. Also, 10 tons of refrigeration were installed and is used in the spawning phase of oyster culture. Mixing different temperature water provides temperature controlled seawater for other phases of oyster farming. A mixing unit is still needed to provide temperature control automatically. In the laboratory in Newark, different sizes and shapes of tanks are being tested. Flow rates are varied in the tanks in order to find flow rates required by the oyster in a closed system. The closed system provides recirculated filtered water and the oysters are fed with corn starch, corn meal, and other artificial foods. Also chemical analysis of the water will provide useful data, showing the chemical change caused by the oysters.

SUPPORTED BY U.S. Dept. of Agriculture

2.1522, THE EFFECT OF POLLUTION ON THE DISTRIBUTION OF LPP PHYCO-VIRUSES IN RELATION TO POLLUTION OF THE CHRISTINA RIVER
M.S. SHANE, Univ. of Delaware, School of Arts, *Newark, Delaware* 19711

The ecology of LPP phyco-viruses will be studied in relationship to pollution in the Christina River. Samples of water from designated stations in the river will be examined for the presence of LPP phyco- viruses and also the host genera of algae. Water quality studies will be performed on the same samples used for biological studies. Parameters like biochemical oxygen demand, dissolved oxygen, total nitrogen or phosphorus, pH, alkalinity, and hardness will be determined.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1523, COLUMBIA RIVER THERMAL EFFECTS STUDY
E.N. KARI, U.S. Dept. of the Interior, Federal Water Quality Admin., *Washington, District of Columbia*

The Columbia River Thermal Effects Study consists of twenty-five separate studies by the three participating agencies. The purpose of the study is to provide a scientific basis for the evaluation of the temperature regime of the main stem Columbia River and its effect on the river's ecology, particularly upon the economically important anadromous and resident fish of the Columbia River.

The study consists of two parts: biological effects and temperature prediction. The objective of the biological effects portion is to develop additional factual data on the water temperature requirements and tolerances of fish of commercial and sports value in the Columbia River. Titles of the biological studies are given on the attached sheet.

The temperature prediction study is by Federal Water Pollution Control Administration and Atomic Energy Commission, with the objective of applying mathematical models of the thermal regime of the Columbia River to allow evaluation and prediction of the overall temperature effects of thermal input and the water management system and to develop an operational plan to minimize temperature effects, and obtain possible benefits.

The biological effects study was commenced in June 1968, and will terminate July 1970.

The mathematical model project was commenced in April 1969, and will terminate June 1970.

Budget data for the project are given on the attached sheet.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1524, SYNERGISTIC EFFECTS OF SUB-LETHAL POLLUTION ON THE DEVELOPMENT OF SELECTED WARM-TEMPERATE AND SUB-TROPICAL FISHES AND CRUSTACEANS
F.A. KALGER, Aquatic Sciences Incorporated, *Boca Raton, Florida* 33432

This project will utilize the output of an established culture facility to determine the synergistic subiethal effects of temperature, oxygen, salinity, and a chlorinated hydrocarbon on the development of selected warm-temperate and subtropical species of fishes and crustaceans. The experimental species have been chosen because they represent forms which occupy subtropical fresh, brackish, or marine waters for all or part of their life histories, such waters and specific habitats being subject to several forms of potential environmental toxicants, their real or potential economic values as sports species, and their adaptability to being cultured with success in the laboratory.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1525, BENTHIC COMMUNITIES
J.L. TAYLOR, U.S. Environ. Protection Agcy., Office of Res. & Monitoring, *Gulf Breeze, Florida* 32561

The chief purpose of estuarine benthic studies is to assess the effects of hurricane barriers, dams, spoil banks, contaminants and other types of artificial alteration. The benthic species-habitat relation is under investigation to correlate fauna and flora with bottom type, salinity, depth and organic distribution. Benthic sediments and biota are obtained by steel traps and dredges at stations located on transects in estuarine systems and neretic areas. Specimens are picked from bottom samples and identified to species. Sub-samples of bottom material are analyzed for raw weight in each size fraction of the texture, weight percent in each size fraction, and percentage of organic carbon. Mean, standard deviation, skewness, and kurtosis of size distribution are obtained.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1526, IRRIGATION OF CITRUS WITH WASTE WATER
R.C. KOO, Univ. of Florida, Agricultural Experiment Sta., *Lake Alfred, Florida*

The proposed research plan involves laboratory, greenhouse and field investigations to determine the feasibility of irrigating citrus with waste water or sewage effluent from citrus processing plants. The main approach will be to grow citrus plants in greenhouses and irrigate them with waste water from citrus processing plants from several locations.

The waste water will be analyzed for appropriate constituents and applied to potted trees of several scion-rootstock varieties of citrus in various amounts for 2 to 3 years. Measurements of plant growth and mineral composition of leaves will be done periodically.

Another facet of the project will involve collecting the leachate of water that has washed over the roots of potted citrus trees. By analyzing the water and subtracting from the known content of the water applied, the removal of various constituents by the roots can be determined.

A young tree field experiment will be initiated on land where waste water is presently disposed. This will be a field test on the use of waste water for citrus and to obtain information on necessary adjustments in cultural practices for citrus.

2. WATER QUALITY

SUPPORTED BY U.S. Dept of Interior - O. Wtr. Res. Rch.

2.1527, AN ECOLOGICAL STUDY OF SOUTH BISCAYNE BAY IN THE VICINITY OF TURKEY POINT
R.G. BADER, Univ. of Miami, School of Marine Science, *Miami, Florida* 33149 (AT(40-1))

This is a study of th ecology of south Biscayne Bay with particular attention to the environs of the Turkey Point power station. The existing damaged and relatively unspoiled areas are being studied with regard to hydrology, chemistry, phytoplankton, zooplankton and benthic organisms. The biology of the organisms will be considered in relation to temperature, salinity, and some gross chemical characteristics. Also, the effect of potentially higher temperatures on the dominant and subdominant species will be studied in the field and in the laboratory. Information presently available in relevant areas of study is being analyzed and utilized in this program.

Because the first two units of the Florida Power and Light Company plant are now in operation, it is necessary to sample several control sites in order to monitor the changes which have already occurred. Some rise in temperature and in the copper and iron content of the water near the effluent have been observed during studies made by this Institute. Damage to the flora and fauna has been noted in an area of about 300 acres off the effluent canal.

SUPPORTED BY U.S. Atomic Energy Commission

2.1528, PHARMACEUTICALS RESEARCH
W.B. DEICHMANN, Univ. of Miami, School of Medicine, *Miami, Florida* 33124

The project will be directed toward: (a) Investigating the role of the blue green algae in the food chain leading to the production of toxins in the barracuda. It is known that certain localities may become toxic because they are favorable to accumulations of wind- or current- driven algae. The role of the increase in water temperature at the Turkey Point nuclear power installation will be investigated. (b) A portion of the meat and organs of large barracuda will be fed to experimental animals. When signs of toxicity develop, the remaining portion of the barracuda will be subjected to chemical analysis and pharmacological and toxicological studies. Various hospitals in the Dade County area will be requested to bring to our attention any cases of barracude poisoning, and to supply us with any remaining barracude meat which was the cause of the intoxication, for analysis and study. (c) An investigation of therapeutic agents from Gorgonians will be initiated. The proposed study will include the determination, localization, distribution, and variation of prostaglandin A2 content in P. homomalla. The products of gorgonian metabolism will be tested for possible therapeutic value.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1529, BIOLOGICALLY ALLOWABLE THERMAL POLLUTION LIMITS - A PHYSICO-CHEMICAL APPROACH
W. DROSTHANSEN, Univ. of Miami, School of Marine Science, *Miami, Florida* 33149

It is proposed to search the literature thoroughly for temperature dependent biological and biochemical phenomena for possible evidence of relative abrupt changes in such systems at discrete temperatures. The data and information collected will be studied in connection with the possibility of delineating 'safe ranges' over which temperature may be varied (in thermal pollution: generally increased), and 'critical temperatures' near which more or less abrupt, and occasionally drastic, changes may take place. Specific attention will be paid to such processes which are likely to be of importance in the maintenance of the ecological balance. Preliminary results show that it appears safe to increase the environmental temperature from ambient, to say, 27 degrees C, whereas an additional increase of 3 degrees might have catastrophic results.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1530, THE BIOLOGY OF THE INFAUNA OF A TROPICAL SOFT BOTTOM AREA
H.B. MOORE, Univ. of Miami, School of Marine Science, *Miami Florida* 33149

A study is in progress on the biology and ecology of the infauna of the soft bottom of Biscayne Bay, Florida. This is considered typical of a tropical estuarine area. Papers have been published on the heart urchin Moira atropos, and the lamellibranch, Tagelus divisus. Papers are in press on Chione cancellata, on the fauna of intertidal muds, on sublittoral polychaetes and the biological effects of pollution in the bay. Studies are in progress on various mollusks, echinoids and brittle stars.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1531, THE BIOLOGY OF TROPICAL BOTTOM INVERTEBRATES
H.B. MOORE, Univ. of Miami, School of Marine Science, *Miami, Florida* 33149

Studies of the effects of pollution in tropical seas requires the basic information of how representative animals live under normal conditions. There is little such information for the tropics. This is a continuing project in which we have published accounts of the ecology of Lytechinus, Tripneustes, Eucidaris, Echinometra, Moira, Chione, and Balanus spp. Studies are in progress on other species of urchins, brittlestars, mollusks and barnacles. Each such study has to be continued for a number of years in order to see associations with varying environmental conditions.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1532, STUDIES OF THERMAL POLLUTION IN BISCAYNE BAY
D.C. TABB, Univ. of Miami, School of Marine Science, *Miami, Florida* 33149

Specific Aims - The overall objective of the research program is to determine the effects of thermal effluent on the macrofauna and -flora of Biscayne Bay, south Florida as successive generators (both conventional and nuclear) come into operation at the Florida Power and Light Company plant site at Turkey Point (Figures 1 and 2). 1. To describe the plant and animal communities in the vicinity of the Turkey Point power plant site in qualitative and quantitative terms, and to relate qualitative and quantitative changes in these communities to changes in environmental parameters, principally temperature. This will be accomplished by utilizing standardized quantitative sampling methods already tested for statistical validity in recent studies for U. S. Public Health Service. These studies were carried out in Florida Bay where the habitat and faunal elements are essentially the same as those expected in southern Biscayne Bay. The sampling will provide accurate data on the kinds and numbers of macroscopic animals and plants in the study area. New information thus obtained will be related to data already gathered from a number of other studies to interpret the fluctuations which will be observed. 2. To integrate all this information plus that in the literature for the development of an accurate estimate of the thermal depth point for the fauna and flora, and to estimate the maximum heat load that the bay can carry while, at the same time, maintaining the ecological status quo. These estimates will be translated into specific recommendations to the proper Federal authorities as to the best disposition of the heated effluent.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1533, INVESTIGATION OF THE EFFECTS OF COMMERCIAL HYDRAULIC CLAM DREDGING ON VARIOUS BOTTOM HABITATS OF SELECTED ESTUARINE AREAS
E.A. JOYCE, State Board of Conservation, *Saint Petersburg, Florida* 33731

Phase II: Objectives - Determine the effects of a commercial hydraulic clam dredge on various bottom habitats of selected

estuarine areas and to learn which species are first to recolonize the disturbed areas.

Procedures: Areas of various habitats selected for dredging will first be surveyed to determine the ecology and sedimentation of the bottoms. Samples of animal and plant life will be taken by various methods so that relative abundance and size of dominant species may be determined prior to dredging.

Ecological analysis of the areas, after dredging, will be made at specific intervals to determine the immediate bottom alterations and subsequent changes in the benthic communities as compared to the results obtained prior to dredging. Time intervals between dredging, and a return to conditions approximating the undisturbed state will be carefully noted. Some of these areas selected from various habitats will be periodically re-dredged to determine the effects of continued harvesting, both on bottom habitats and clam production.

Part 2 of 4.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.1534, IMPLEMENTATION OF HABITAT ALTERATIONS

R.L. WILBUR, State Div. of Game & Fish, *Tallahassee, Florida* 32301

Objectives: The objective is to implement and record habitat alterations in each study lake.

Procedures: Habitat alterations will be implemented in three study lakes ; 1. Trout Lake. 'The Mud Cat' (a dredge made by Inland Service Co.) will be used to remove as much of the bottom muds as possible. The amount of mud removed will be limited by finances, water and mud depths, types of muds, obstacles, size of sump area, etc. Detailed records will be kept of the types, depths, and locations of the muds removed. Changes in the aquatic flora will be documented by frequent observaton. Changes in the benthos associated with the altered habitats will be investigated (before and after Ekman dredge samples). Three before and three after samples of the water quality will serve as an indication of changes in the latter. 2. Lake Carlton. A sand dredge will be used to pump sand from central lake areas to areas immediately adjacent to the existing littoral zone. The pumped sand will be used to convert these deep (8' to 14') muck-bottom areas to shallower (4' to 6') sand-bottom areas and may thereby serve to expand the littoral zone. The holes or trenches left by the dredge will hopefully collect muck sluffed into the holes by bottom currents. Attempts will be made to document the extent to which this occurs. Changes in the depth contours, bottom types, etc. will be fully documented. Invasion of aquatic plants into the pumped sand areas will be recorded, if such occurs. If not, attempts may be made to stimulate plant growth. Changes in the invertebrate population will be studied. Water quality samples will be taken three times before and three times after the dredging operation. 3. Maxwell's Pond. A 2- acre cove (presently 10' deep) will be filled to depths of 3 to 6 feet with sand obtained from a sand dredge which will pump from the center of the lake. Attempts will be made to stimulate growth of submergent and emergent aquatic plants in the filled area, the purpose being to create a marsh area. Changes in the flora and invertebrate populations in the altered areas will be monitored. Water quality will be sampled three times prior to dredging and on a quarterly basis following dredging.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1535, POLLUTION OF THE HUISME

UNKNOWN, Sogreah, *Grenoble, France*

Study of polluted waters in Huisme basin.

SUPPORTED BY Loire & Bretagne City Govt. - France

2.1536, PARABIOTIC GROWTH CHARACTERISTICS OF SELECTED SEWAGE BACTERIA

E.L. FINCHER, Georgia Inst. of Technology, School of Biological Sciences, *Atlanta, Georgia* 30332

Microbial ecosystems constitute a fundamental basis for the chemical dissimilation of natural and artificial wastes in aqueous systems. The qualitative and quantitative changes which occur in these systems are the expression of successive populations developing under the influence of nutritional substrates and in response to chemical pressure between different types of microorganisms present in the system.

The proposed research will be concerned with design, construction, and evaluation of a parabiotic growth system and the study of population dynamics of quasi-mixed bacterial cultures.

Pure cultures of heterotrophic aerobic bacteria isolated from raw sewage, activated sludge, and sludge effluent will be grown in the parabiotic growth system. Design of this system will maintain physical separation of the developing populations but will permit complete and constant chemical interchange between the populations.

Growth dynamics of multiple populations will be determined by growth rates and biomass and the conditions of growth system characterized by measurement of hydrogen-ion concentration and dissolved oxygen. Synthetic and natural substrates, including sewage extract will be studied for effects on population interactions. Initial studies are planned to determine the response of these characterized ecosystems to specific chemical pollutants.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1537, EFFECT OF A KRAFT PAPER MILL ON THE ECOLOGY OF A GEORGIA ESTUARY

M. DAHLBERG, Univ. of Georgia, Marine Institute, *Sapelo Island, Georgia* 31327

This study surveys the ecology of a natural Georgia estuary in an attempt to determine possible effects of a newly established kraft paper mill located at the head of the estuary. This study will analyze the impact of the mill by studying seasonal and zonal distributions of fishes and invertebrates and by analyzing chemical and physical parameters including salinity, temperature, current, pH, color, turbidity, dissolved oxygen, COD and BOD. Toxicity bioassays are conducted in the laboratory.

SUPPORTED BY Georgia State Government

2.1538, A STUDY OF ECOLOGICAL SUCCESSION FOLLOWING NATURAL AND MAN-INDUCED CHANGES ON A TROPICAL REEF

R.S. JONES, Univ. of Guam, Graduate School, *Agana, Guam* 96910

A new oil-fired power plant is now under construction at Tanguisson Point on the west coast of Guam. The primary objectives of this study are to identify and measure the effects of changes on the reef organisms and ecosystem caused by natural changes and those induced by pollution in this area. The major categories of changes anticipated are as follows: Intake and outfall channels are to be blasted through the reef flat to provide them with an access to seawater for a condenser coolant. These channels offer a unique opportunity to measure successional changes on their newly denuded surfaces. Baseline data established at this time on the normal rate to denote changes in the ecosystem that may be induced when the plant becomes operational and heated waters are released. In addition to the man-induced changes, the Tanguisson Point study area falls within a zone of previous biological catastrophe. In the past three years, there has been an invasion of the crown-of-thorns starfish, Acanthaster planci. This animal has destroyed most of the living coral in the area. The study will consider the deleterious effects of A. planci on the reef ecosystem and will seek to determine the rate of reef recovery and components of succession in the devastated area.

These problems are to be attacked using a variety of transecting methods and in situ oceanographic instruments. We intend to establish baseline data for physical parameters, such as current patterns, temperature regime, topography, water characteristics, and biological parameters such as species composition and biomass.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1539, THE EFFECTS OF THERMAL LOADING ON THE HAWAIIAN MARINE BIOTA
V.E. BROCK, Univ. of Hawaii, Hawaii Inst. of Marine Biology, *Honolulu, Hawaii* 96822

A wide variety of Hawaiian shallow-water marine organisms will be subjected to a free flow of freshly pumped and warmed sea water at several temperature levels above ambient and at ambient as controls for extended periods of time. Measurements of preferred temperatures of mobile marine organisms will be made in a vertical thermal gradient apparatus in which the gradient levels can be rapidly and accurately changed. Temperature reactions of both acclimatized and naive organisms will be measured.

Lethal temperatures will be determined and both short and long term responses to sublethal temperatures will be measured as it affects various biological processes. These determinations and responses will also be made for various life history stages. These measurements will give new information on the responses of the experimental organisms to warmed sea water and insights into possible changes in nearshore marine ecosystems which the important components of flows of warmed effluents may occasion.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1540, POLLUTION EFFECTS ON GROUND WATER RECHARGE IN HAWAII
L.S. LAU, Univ. of Hawaii, Water Resources Research Ctr., *Honolulu, Hawaii* 96822

Determination of the absorptive and adsorptive capacities of Hawaii soils and fractured rocks with respect to certain potential pollutants of the underlying basal ground water bodies, including sewage constituents and selected pesticides that are applied through agricultural uses. Determination of quantitative and qualitative effects of recharge of the basal ground water by non-potable waters, including quantity and head increases, flow pattern and dispersion, fate and travel of pollutants after reaching the ground water bodies.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1541, SAND RECOVERY
R.Q. PALMER, Univ. of Hawaii, School of Engineering, *Honolulu, Hawaii* 96822

Work will be concentrated in two areas:

(1) Recovery Technology: To date the majority of offshore sand mining ventures have been carried out using conventional channel and harbor dredges. Improvement and modification of this equipment as well as development of new concepts to operate efficiently in the offshore zone are needed. A model test facility will be set up in the lab with the intention of working with the dredging industry toward the improvement of technology in this area. Promising concepts might then be ocean-tested as dictated by available funds.

(2) Ecological Effects: The possible ecological effects of offshore sand mining in Hawaii will be examined with particular emphasis on reef and marine life and disturbance of recreational use of the coastal zone. Close cooperation will be sought with the departments of Marine Biology, Zoology, and Oceanography.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1542, EFFECTS OF SILTATION AND COARSER SEDIMENTS ON DISTRIBUTION AND ABUNDANCE OF STREAM-INHABITING INSECTS
M.A. BRUSVEN, Univ. of Idaho, School of Agriculture, *Moscow, Idaho* 83843

The proposed research will involve laboratory and field investigations to determine the effects of artificially introduced silt and coarser sediments on the distribution and abundance of stream insects. Insects will be quantitatively and qualitatively evaluated before and after artificial sediment introduction. Correlations will be made between sediment displacement and recolonization by insects.

Laboratory investigations will employ the following methods: (1) Artificial streams with differing bottom types will be used to study micro-distribution of principal stream insects. (2) Relative tolerances of insects to different sediments will be investigated.

Field Investigations: (1) Different sediment gradients will be artificially introduced into streams. (2) Temporal changes in standing crop of insects will be measured and correlated with sediment displacement. (3) Insect tolerances to different types and degrees of sedimentation will be studied. (4) Recolonization rate in relation to sediment displacement will be studied.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1543, DISTRIBUTION AND ECOLOGY OF AQUATIC INSECTS OF IDAHO
M.A. BRUSVEN, Univ. of Idaho, Agricultural Experiment Sta., *Moscow, Idaho* 83843 (IDA00542)

OBJECTIVE: Inventory the aquatic insects of Idaho to determine their distribution and abundance. Study the biology of the aquatic insects, life histories, ecological habitats, inter-and intraspecific relationships with other animals, parasites and predators, food habits, and importance to man and domestic animals. Study population dynamics of insects in selected aquatic habitats to evaluate biological and physical effects of the environment on the population.

APPROACH: The fauna, distribution, biology and ecology of aquatic insects in streams, lakes, ponds, reservoirs, drainage and irrigation ditches. Various techniques for collecting employed; bottom scrapers, Surber bottom samplers, aquatic seines, nets and dredges. An evaluation will be made of water chemistry, substrate, depth of water, turbidity, temperature, food and inter- and intraspecific relationships.

PROGRESS: The food habits and ecology of mayflies of the St. Maries River was completed. Drift samples collected during squawfish eradication on the St. Joe River have been sorted and evaluated volumetrically. One paper has been published and another is in preparation from the latter study. Aquatic insect distribution and abundance studies in relation to the evaluation of the before, during and after effects of logging on stream insects were continued for the second year. Bottom samples, stream profile, bottom type and sediment classification were made in July and August. Similar studies to evaluate the effect of silt pollution from mining on stream insects was initiated. Stream-sediment simulation studies were conducted in the laboratory commensurate with the field studies to more critically evaluate insect tolerances to siltation.

SUPPORTED BY U.S. Dept. of Agriculture

2.1544, POLLUTION EFFECTS ON ADULT STEELHEAD MIGRATION
D.W. CHAPMAN, Univ. of Idaho, Cooperative Fishery Unit, *Moscow, Idaho* 83843

Water quality conditions on the now free-flowing lower Snake River downstream from Lewiston, Idaho are expected to change after the proposed impoundment by Lower Granite dam.

Migrational patterns of adult steelhead now passing through the lower Snake River are being studied and compared with existing water quality parameters to find significant correlations between migrational patterns and water quality before and after impoundment by Lower Granite dam.

Impoundment is expected to cause the following changes: (1) lowered dissolved oxygen levels with extreme diel fluctuations; (2) higher mean temperatures; (3) localized accumulations of sludge deposits; (4) locally high nitrogen levels; and (5) reduced guiding influence of water current. Anticipated changes in the Lower Granite pool are even greater, however, because of Kraft pulping waste input high in biochemical oxygen demand, suspended solids, and organic compounds significantly toxic or confusing to the olfactory senses of fish. Steelhead migrational paths and travel rates are being assessed in the pre-impoundment phase by sonic tags while associated water quality conditions are being measured and mapped. Similar tracking and water analysis after impoundment will establish the impact of altered water quality upon total numbers, migrational rates, and paths of adult steelhead through the reservoir.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1545, POLLUTION EFFECTS ON ADULT STEELHEAD MIGRATION

D.W. CHAPMAN, Univ. of Idaho, Cooperative Fishery Unit, *Moscow, Idaho* 83843

Migrational behavior of adult summer steelhead trout in the middle Snake River is being correlated with water quality before and after limnological conditions are altered by construction of Lower Granite Dam on the middle Snake River. Anticipated changes in the Lower Granite pool area (lowered dissolved oxygen levels with extreme diel fluctuations, higher mean temperatures, reduced guiding influence of water current, and localized accumulations of sludge deposits) are even greater because of a Kraft process pulp and paper operation at Lewiston, Idaho. The 40 mgd Kraft pulping waste output is typically acidic, high in biochemical oxygen demand, suspended solids, and compounds significantly toxic so as to confuse the olfactory senses of fish. Steelhead are being fitted with ultra-sonic transmitters and tracked to compare the following parameters before and after impoundment: (1) Mean travel times through this stretch of river; (2) General migration pathways; and (3) Behavior at specific points in the channel. Travel paths of individual fish will be mapped and then related to specific aspects of water quality. Significant correlations are then to be tested under experimental conditons in artificial stream channels.

This impact of industrial pollution upon anadromous fish in fresh water will be of value in predicting the outcome of impounding other free flowing polluted streams.

The pre-impoundment phase of this project was initiated in September, 1968 and will be completed in August, 1971.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1546, GREAT LAKES ECOLOGY STUDY

P.F. GUSTAFSON, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-26)

This is a new program whose objective is to conduct field and laboratory research to examine the influence of nuclear power plant operations on the physical and biological systems in Lake Michigan. The environmental stress from nuclear plants discharging cooling water in the lake is two-fold; thermal and radiation. Field measurements will be made at existing steam generating (coal-burning) plants to examine thermal effects on lake chemistry, and biota including benthic, floating, and free swimming organisms. Temperature and current measurements in and around the thermal discharge (plume) will be made. Baseline data for radioactivity will be obtained in water, sediments, and biota. These efforts will be closely coordinated with similar new and ongoing work at universities and other institutions in the Lake Michigan area.

Results to date: Since this is a new program, the only accomplishments to date have been to assemble staff, equipment, and to develop a research plan.

SUPPORTED BY U.S. Atomic Energy Commission

2.1547, LAKE MICHIGAN THERMAL STUDIES

L.E. LINK, Argonne National Laboratory, *Argonne, Illinois* 60439

The purpose of this effort is to determine the short and long range effects of nuclear power plant siting on Lake Michigan and consists of three basic activities: 1) Publication and updating of state-of-art reports on analytical and physical scale modeling techniques for prediction of temperature profiles in the vicinity of the outfall and review of field studies of thermal discharges at actual power plant sites. 2) Development of analytical techniques for predicting the dispersion characteristics, temperature field, and gross behavior of the thermal plume produced by a lakeshore power plant. 3) Design and analysis of field experiments to measure temperature and lake current patterns in the vicinity of power plant outfalls.

The recent ANL report - 'Effects of Thermal Discharges on the Moss/Energy Balance of Lake Michigan'- discussed the large scale impact of man-made thermal discharges into Lake Michigan and concluded that the increase in average lake temperature and water loss due to evaporation as a result of these heated discharges are 'negligible and will continue to be so for the rest of this century.'

SUPPORTED BY U.S. Atomic Energy Commission

2.1548, APPLICATION OF SEWAGE SLUDGE TO FIELD CROPS

R.I. DICK, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

Investigations are being carried out to evaluate the effect of digested sludge constituents on crops, land, and on ground and surface water. Particular attention is being given to the fate of nitrogen in sludge. Possibilities for removing nitrogen by ammonia volatilization before and during application are being evaluated as are the possibilities for removal by denitrification following nitrification in the soil.

SUPPORTED BY Chicago City Government - Illinois

2.1549, POLLUTION TOLERANCE OF SELECTED ALGAE

T.M. MCCALLA, Univ. of Udaipur, *Udaipur, Rajasthan, India* (A7-SWC-83)

OBJECTIVE: Determine the physiological and ecological factors determining growths of algae in polluted waters and study the pollution tolerance of selected species of algae.

APPROACH: Detailed physical and chemical analysis of the waters with special reference to organic matter and other pollutants. A comparison will be made between algal abundance in waters immediately after the site of intake of industrial effluents with that in waters distal to the point of discharge, and differences between algae of polluted water and those of relatively clean water.

PROGRESS:

2.1550, MICROBIOLOGY OF THERMALLY POLLUTED ENVIRONMENTS

T.D. BROCK, Indiana University, School of Arts, *Bloomington, Indiana* 47401 (AT)

This study concerns effects of temperature on the growth and metabolism in nature of bacteria and algae which live in thermal environments. Both natural and man-made thermal environments will be studied. Specific areas to be investigated: Microbial colonization of environments with wide fluctuations in temperature; Rate of adaptation to the new temperature after a sudden increase in temperature; the use of Thermus aquaticus as a possible indicator of thermal pollution; the relationship between temperature responses and the pH of the water.

THe effects on microbial activity of thermal pollution of the Wabash and Jordan Rivers in Indiana have been studied. Isotope methods have been used to determine the temperature optima of the resident bacteria.

SUPPORTED BY U.S. Atomic Energy Commission

2.1551, ACID MINE POLLUTION EFFECTS ON LAKE BIOLOGY

D.G. FREY, Indiana University, Water Resources Research Ctr., *Bloomington, Indiana* 47401

This study is designed to yield comparative information about the ecosystems of coal strip-mine lakes. It will afford as complete a description as possible of the physical and chemical nature of a series of these lakes at different stages of recovery from acid-mine pollution, including the seasonal changes which occur.

The nature of the biological communities of these lakes will be intensively investigated in order to document the effects of acid-mine pollution on the structure and dynamics of ecosystems. Thus, a detailed understanding of both the seasonal (short-term) and successional (long- term) changes in community structure, diversity, abundance, and amounts and rates of energy flow in strip-mine lake ecosystems will result. This will also constitute a contribution to the theory of ecosystems in general.

2. WATER QUALITY

The study will attempt to determine, by field and laboratory experiments in addition to the observations outlined above, (1) the degree of recovery from acid pollution necessary to allow establishment of healthy aquatic ecosystems (including fish) in strip-mine lakes and (2) practical methods of treatment for mine lakes to promote the establishment of such communities.

2.1552, EFFECT OF HEATED WATER DISCHARGE FROM IPALCO'S PETERSBURG PLANT ON THE WATERS OF WHITE RIVER, INDIANA

D.G. FREY, Indiana University, Water Resources Research Ctr., *Bloomington, Indiana* 47401

The project area is in southwestern Indiana, just below the junction of the East Fork and West Fork of the White River, Pike County, Indiana.

A thorough investigation of the physical, biological, and chemical characteristics of the river will be made over a three-year period, including one year before construction of the new steam-electric generating plant, and one year after, in order to determine the effects of thermal pollution.

It is anticipated that this investigation will result in information that will be useful not only to the power-producing company but also to the power-regulating State agency.

The investigation of several parameters, such as temperature, dissolved oxygen, fishes, BOD, plankton, turbidity, and bottom fauna has produced significant data in the past three years. The continuation of the project for another three years will permit us to continue to assess the effect of Unit No. 1, and the added effect of Unit No. 2 beginning in 1969.

This project will also include a microbiologic study by Thomas D. Brock and Warren Silver as part of an AEC contract.

SUPPORTED BY Indiana University - Bloomington

2.1553, THE RESPONSE OF FISH POPULATIONS TO HEATED EFFLUENTS

J.R. GAMMON, Depauw University, School of Liberal Arts, *Greencastle, Indiana* 46135

1. To describe the qualitative and quantitative changes in the species composition of fish in a segment of the Wabash River which will receive waste heat from an electric power generating station beginning in 1970.

2. To examine the effect of the thermal additions on the production of fish by comparing growth rates and condition factors of species populations prior to and after the introduction of heated effluents.

3. To measure the harvest of fish by sport and commercial fishermen in relation to the standing crop and to evaluate the impact of the changed population composition on the fishery.

4. To explore the use of the RNA:DNA ratio of fish liver as a possible biochemical indicator of short-term thermal effects.

5. To examine the thermal requirements of some important sport and commercial species of fish in laboratory investigations from egg development, hatching and early fry stages.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1554, THE EFFECT OF INORGANIC SEDIMENT ON STREAM BIOTA

J.R. GAMMON, Depauw University, School of Liberal Arts, *Greencastle, Indiana* 46135

Large quantities of sediment annually carried to the oceans complicate water treatment, reduce recreational values of water, shorten reservoir life and probably affect aquatic life also. Since quantitative studies are lacking the populations of fish in pools and macroinvertebrates in riffles of a small stream were studied in relation to a crushed-rock quarry. During years of heavy sedimentation the populations become much reduced in density, while recovery occurs during summers of low sedimentation. Few organisms are tolerant of the sediment and carpsuckers and gizzard shad appear to be notably intolerant. Standing crop fluctuate in inverse relation to the quantity of sediment introduced, but diversity indices exhibit no uniform pattern. Age and growth analyses and the length-weight relationships may reveal individual organismic responses to sedimentation.

2.1556, WATER QUALITY - CEDAR BLUFF IRRIGATION DISTRICT, KANSAS

R.B. LEONARD, U.S. Dept. of the Interior, Geological Survey, *Lawrence, Kansas*

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of Kansas.

Purpose: To determine the effect of irrigation on the chemical quality of ground water and of streamflow in and adjacent to the district.

Methods: Chemical-quality data with related measurements are collected periodically at about 90 observation wells. The effect of effluent ground water and irrigation waste water on the quality of streamflow is evaluated by a combined seepage-salinity surveys of the Smoky Hill River at the beginning and end of each irrigation season. Continuous conductivity and stage records, and daily records of irrigation releases are used to evaluate the amount and quality of water moving through and adjacent to the district.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.1557, EFFECTS OF POLLUTION, ESPECIALLY FROM FEEDLOTS, ON FISHES IN THE UPPER NEOSHO RIVER BASIN

F.B. CROSS, Univ. of Kansas, State Biological Survey, *Lawrence, Kansas* 66044

Ascertain status of fish populations in the upper Neosho River Basin, Kansas; interpret species-composition relative to pollution caused by livestock wastes, utilizing similar data obtained before and immediately after extensive fish-kills in 1967 (caused by feedlot wastes). Obtain information on habitats, reproduction, size and age- composition, and food habits of one species of fish that proved especially sensitive to pollution in 1967, and one species that proved especially tolerant of it.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1558, EFFECTS OF FEEDLOT RUNOFF ON FISH FOOD ORGANISMS IN THE COTTONWOOD RIVER

C.W. PROPHET, State Forest. Fish & Game Com., *Pratt, Kansas* 67124

Objective: To assess the effects of feedlot runoff on benthic macroinvertebrates in the lower Cottonwood River.

Procedure: 1. An attempt will be made to identify other major sources of pollution in addition to commercial livestock feedlots along the lower Cottonwood River: 2.Diversity per individual (d) of benthic macroinvertebrates will be determined periodically for selected reaches of the Cottonwood River and the Neosho River from Elmdale to Hardford:3.Sampling sites used during the previous segment will again be used and new sites will be selected to evaluate relative ecological effects of municipal and industrial discharges directly into the river as well as effects of discharges from sources along major tributary streams: 4.Differences between d values from each sampling station will be analyzed to determine their significance.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1559, INFLUENCE OF THE EFFLUENT FROM A CONCENTRATED INDUSTRIAL COMPLEX ON A LARGE RIVER - FISH DISTRIBUTION
H.M. HANCOCK, State Dept. of Fish & Wl. Rso., *Frankfort, Kentucky* 40601

Objectives: To determine if industrial complex effects distribution of fishes.

Procedures: Distribution of fishes will be studied using gill net and hoop net sets in the control area (mile 19 or above) and in various stations below the outlets of the industrial plants (mile 17.7 - mile 2.5). Net sets will usually be made horizontally at or near mile points.

Part 1 of 7.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.1560, INFLUENCE OF THE EFFLUENT FROM A CONCENTRATED INDUSTRIAL COMPLEX ON A LARGE RIVER
H.M. HANCOCK, State Dept. of Fish & Wl. Rso., *Frankfort, Kentucky* 40601

Objectives: To determine if effluent is harmful to any species of fish.

Procedures: Effect of the industrial effluent on fishes will be studied by placing fishes caught in Job A into wire cages which measure 3 ft. x 5 ft. These cages will be located in the control area and in at least three stations in the effluent fan. Physical condition of caged fishes, after various periods of entrapment, will be compared.

Part 2 of 7

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.1561, INFLUENCE OF THE EFFLUENT FROM A CONCENTRATED INDUSTRIAL COMPLEX ON A LARGE RIVER - WATER QUALITY EFFECTS
H.M. HANCOCK, State Dept. of Fish & Wl. Rso., *Frankfort, Kentucky* 40601

Objectives: To determine the water quality in the control section of the river and in the affected area.

Procedures: Water quality will be determined from samples taken at various mile points above and below the industrial complex. Dissolved oxygen, pH, total hardness and conductivity will be determined in the field. Duplicated samples will be returned to Murray University chemistry laboratories in inert containers to be analyzed for inorganic chemicals by atomic absorption and for organic chemicals by gas chromatography. Approximately 437 hours chemical consultation will be required for this job.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.1562, INFLUENCE OF THE EFFLUENT FROM A CONCENTRATED INDUSTRIAL COMPLEX ON A LARGE RIVER - BENTHOS DISTRIBUTION
H.M. HANCOCK, State Dept. of Fish & Wl. Rso., *Frankfort, Kentucky* 40601

Objectives: To determine the effects on the industrial complex of the distribution of benthos.

Procedures: The distribution of benthos will be determined by taking bottom samples by use as many mile points and also as many stations across the river as possible. These samples will be identified as to micro and macro benthos in Murray University biology laboratory. Approximately 435 hours of biological consultation will be required to complete this work.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish

2.1563, INFLUENCE OF THE EFFLUENT FROM A CONCENTRATED INDUSTRIAL COMPLEX ON A LARGE RIVER
H.M. HANCOCK, State Dept. of Fish & Wl. Rso., *Frankfort, Kentucky* 40601

Objectives: To determine chemical content of the muds of the control section of the river and of effected area.

Procedures: Chemical content of bottom muds will be determined from selected mud samples by atomic absorption and gas chromatography. Differences between control and influenced area muds will be recorded. Approximately 334 hours chemical consultation will be required for this job.

Part 5 of 7.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.1564, INFLUENCE OF THE EFFLUENT FROM A CONCENTRATED INDUSTRIAL COMPLEX ON A LARGE RIVER - CHEMICAL CONCENTRATION IN FISH
H.M. HANCOCK, State Dept. of Fish & Wl. Rso., *Frankfort, Kentucky* 40601

Objectives: To determine if fishes are concentrating in their tissues any effluent chemicals.

Procedures: Fish tissues will be ashed and tested for organic and inorganic materials to determine if fishes are concentrating any of these components of the industrial complex's waste. Most of the fish tested will be taken from the fish cages (Job B). Approximately 334 hours chemical consultation will be required for this job.

Part 7 of 7.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.1565, DETERMINATION OF THE EFFECTS OF OIL IMMERSION ON SWAMP RABBITS
L.K. NELSON, State Dept. of Fish & Wl. Rso., *Frankfort, Kentucky* 40601

Objective: To determine the effects of oil immersion on swamp rabbits.

Procedure: In order to gather data on the effects of oil immersion on individual swamp rabbits from oil pollution occurring during flooding periods in the bottomlands, visits will be made by boat in search of rabbits so affected. Some of these rabbits will be netted, ear tagged for future identification, and placed in the same spot as originally found. An attempt will then be made to check the condition of these individual rabbits by daily visits, if practical, to the area where they were found. Records will be kept on their physical condition, as determined by the observer, and on their fate. If deemed necessary, necropsies or autopsies will be performed to determine their physical state or cause of death.

The facilities of the Animal Diagnostic Laboratory of the Kentucky Department of Agriculture at Hopkinsville, Kentucky will be utilized when necessary.

Experimentation may be conducted on swamp rabbits collected by netting during flooding periods in the bottomlands in pens constructed on the Higginson-Henry Wildlife Area near Morganfield, Kentucky. Rabbits will be immersed in crude oil and the effects of such immersion on the condition of the animal and its fate will be observed and recorded. Attempts will be made to conduct this experimentation during periods of varying weather, including cold and wet weather, when the effects of exposure would be expected to be the greatest.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1566, TOXICITY OF POLLUTANTS TO STRIPED BASS
J.S. HUGHES, State Wildlife & Fish Comm., *Baton Rouge, Louisiana* 70804

Objectives: (1) To determine the toxicity of pollutants to various sizes of striped bass.

Procedures: Striped bass ranging in size from fry to six inches in length will be used for these toxicity studies. Standard bioassay techniques will be followed. Dilution water will be from Bayou DeSiard, a lake adjacent to the laboratory. The water quality will be checked before each series of tests. Bioassays will be run at 22 degrees Centigrade.

Pollutants that will be included in this study are paper mill wastes; oil well effluents; wastes from sugar cane mills; rotenone; antimycin A; and pesticides, such as, 2,4-D, 2,4,5-T, silvex, endothal, diquat, dylox, methyl parathion, DDT, and endrin.

Total survival, total mortality and the TLm will be reported for 24, 48, 72, and 96 hours.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1567, BIOLOGICAL CHARACTERISTICS OF WORM POPULATIONS IN GROWING AREAS
E.P. CREASER, State Dept. of Sea & Sh. Fish., *Augusta, Maine* 04330

Objective: To determine certain biological characteristics of worm populations in different types of growing areas.

Procedure: The growth rates of bloodworms will be determined from monthly length-frequency data. The age composition of sandworms and bloodworms will be established by both length and weight distribution for various areas in the Sheepscot River. A continued investigation of the sexual maturity characteristics, spawning behavior, migration and mortalities will be conducted during the spring and early summer. Evidence of a prespawning mortality of mature bloodworms will be checked out. The male, female, nonspawner ratio for all lengths of sandworms will be checked. Diving techniques will be employed in the study of spawning behavior and the estimations of subtidal worm populations. Studies of sandworm and bloodworm eggs and sperm will continue for the Sheepscot River, and include the Sasonoa River where it is thought that the addition of warm water from a nuclear power plant under addition of warm water from a nuclear power plant under construction may affect egg development or spawning.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.1568, THE EFFECT OF HEATING WATER EFFLUENTS ON THE LOWER NEUSE RIVER ESTUARY
D.B. HORTON, Res. Inst. of the Gulf of Me., *Portland, Maine* 04103

The objectives of the project are to provide a description of the physical characteristics and structure of the water column of the estuary and a survey of the benthic invertebrate population before the installation of a nuclear-fueled power plant. A major objective is to predict by simulation, the effect of passage of small fish and invertebrates through the reactor condenser tubes.

SUPPORTED BY No Formal Support Reported

2.1569, WATER QUALITY - BENTHIC INVERTEBRATE RELATIONSHIPS IN ESTUARIES
D. DEAN, Univ. of Maine, Ira C. Darling Ctr. for Res., *Walpole, Maine* 04573

This project proposes to investigate the relationships between water quality and benthic invertebrates in Maine estuaries. Studies will be conducted in three estuaries, the Penobscot, the upper reaches of the Damariscotta and the Sheepscot, representing heavily polluted, moderately polluted and unpolluted conditions, respectively. Comparable portions of each estuary will be studied to determine the benthic communities present, the settlement of benthic invertebrate larvae, larval metamorphosis, and the growth and survival of juvenile forms. Hydrographic, chemical and geological parameters of the waters and sediments will be measured and used as guidelines for controlled laboratory experiments on larval settlement.

The results of this project should aid 1) in the interpretation of fish distribution patterns in estuaries subject to different levels of pollution and 2) in predicting biotic changes that would occur in an estuary subjected to increased or decreased pollution loads.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1570, AN ENVIRONMENTAL SURVEY OF THE DAMARISCOTTA RIVER ESTUARY, LINCOLN COUNTY, MAINE
B.J. MCALICE, Univ. of Maine, Ira C. Darling Ctr. for Res., *Walpole, Maine* 04573

The present environmental characteristics of the Damariscotta River may be significantly altered by the construction of a sewage treatment plant in the upper estuary.

Temperature and salinity distribution, the volume of fresh water entering the estuary, current velocities, and basin topography are being used to derive a picture of the salt balance, exchange rates, and circulation patterns. The summer flushing time is on the order of 3 weeks. Maps of 37 bottom grab samples have used to construct a preliminary sediment distribution in the estuary.

Intensive sampling of inorganic nutrient species is being carried out to determine the nutrient distribution in the estuary and the influence of present small quantities of raw sewage on the distribution.

Hydrographic and nutrient data will be used to predict the effect of the proposed treatment plant on the environmental characteristics of the estuary.

SUPPORTED BY Maine State Government

2.1571, DETERMINE EFFECTS OF RESERVOIRS ALONG SUSQUEHANNA RIVER ON SEDIMENT BEING DISCHARGED INTO CHESAPEAKE BAY AT HAVRE DE GRACE, MD.
J.H. MANNING, State Dept. of Ches. Bay Afrs., *Annapolis, Maryland* 21404

The objectives of this study are to determine the effects of the Susquehanna reservoir on the sediment being discharged into the Bay by the Susquehanna River.

During the fall of 1968 samples will be collected from the water and from the bottoms of several of the reservoirs. Samples will also be collected during the spring freshet of 1969. The mineralogic composition of each of the samples will be determined microscopically and by x-ray diffraction. The size distributions will be determined by sedimentation using a standard pipette method and a Mine Safety Appliance Particle Size Analyzer. The results will be used to evaluate the role of the reservoirs in the downstream fractionation of the Susquehanna River's sediment load.

This study will be conducted by Dr. J. R. Schubel, Chesapeake Bay Institute, The Johns Hopkins University.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.1572, COOLING WATER DISCHARGE PROJECT (RP-49)
L.D. JENSEN, Johns Hopkins University, School of Arts, *Baltimore, Maryland* 21218

Study the physical and biological impacts of discharging central electric power station condenser cooling water into rivers, lakes and estuaries. Eleven utilities are collecting temperature and meteorological data which is sent to project for analysis. Biological studies are being conducted at two sites and two more sites are to be activated in Summer 1969. Cooperation of industry and public agencies is very significant. Project will serve in coordinating capacity in other industry studies of cooling water problems.

Data collection and surveys conducted at 12 plus or minus sites throughout the U.S.A. All analytical work is at the University.

SUPPORTED BY Edison Electric Institute - New York, N.Y.

2.1573, AN ECOLOGICAL STUDY OF THE PATUXENT ESTUARY
R.G. BROWN, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (MD-F-020)

OBJECTIVE: Study the effect of heated water from the Chalk Point plant of the Potomac Electric Power Company on the plants.

APPROACH: Ecological and taxonomic study of the vascular plants of the Patuxent estuary.

PROGRESS: Yield and mineral content of the four marsh species Typha, Spartina, Phragmites and Zizania are being studied. Six quarter meter quadrates along a transect line were laid out and replicated three times. Harvest was biweekly, all plants were harvested at ground level to give yield records.

SUPPORTED BY Maryland State Government

2.1574, EFFECTS OF THERMAL POLLUTION ON PRODUCTIVITY AND STABILITY OF ESTUARINE COMMUNITIES
J.A. MIHURSKY, Univ. of Maryland, Natural Resources Institute, *College Park, Maryland* 20740

A multidisciplinary investigation is proposed to study thermal pollution of an estuarine community. Laboratory studies of behavioral, metabolic and growth responses to heat stress will be integrated with field experiments to evaluate the overall impact of thermal pollution on an estuarine ecosystem.

Specifically, the laboratory phase will study representative species from the phytoplankton and planktonic herbivores. Growth of algae and intrinsic rates of increase of copepod populations will be used to evaluate thermal stress separately and when other environmental components are varied. At the same time, survival, behavior and metabolism of vertebrates and macro-invertebrates will be measured in gradients of temperature and salinity.

Field experiments will determine the influence of heat pollution on several trophic levels. Rates of mortality, biomass turnover or production and energy flow will be used to evaluate the impact of pollution. An ideal field situation has been provided by the newly constructed electrical generating plant at Chalk Point on the Patuxent river estuary.

The field experiments may be divided into those which test the direct effect of the passage of a part of the estuary through the power plant. The indirect effect of effluent water on the planktonic community adjacent to the power plant may be determined by correlation and comparison with pre-existing patterns of biomass, production and species structure of the plankton. Similarly, pre-pollution-phase measurements of vertebrate and macro-invertebrate standing stocks may be correlated and compared with those existing under thermal pollution.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1575, THE EFFECTS OF THERMAL LOADING AND WATER QUALITY ON ESTUARINE PRIMARY PRODUCTION
J.A. MIHURSKY, Univ. of Maryland, Natural Resources Institute, *College Park, Maryland* 20740 (C-1401)

The proposed research plan involves field and laboratory investigations directed towards determining the effects on estuarine primary production and standing crops by a) steam electric station operation, and b) nutrient additions. In addition, field studies will also examine the ecological role of fresh tidal marshes with regard to the utilization of nutrients from domestic sources.

Field investigations will include routine determinations of: (1) primary production by carbon-14 uptake (2) chlorophyll a (3) temperature (4) conductivity (5) salinity (6) methyl orange alkalinity (7) pH (8) inorganic PO4 (9) total PO4 (10) NH3 (11) NO2 (12) NO3 (13) dissolved organic nitrogen (14) particulate nitrogen (15) particulate carbon (16) dissolved carbon (17) particulate carbohydrate. The above determinations will be made on a tidal system ranging from fresh water to about 15 parts per thousand salinity.

Laboratory investigations will examine (1) the effects of temperature changes on natural estuarine and uni-algal populations held in specially designed incubation chambers and thermal gradient blocks and (2) the effects of nutrients viz. NO3, PO4 etc. on primary activity of natural estuarine and uni-algal populations. Measurements of photosynthetic activity under laboratory conditions will be made by the carbon-14 technique, chlorophyll a content and density estimates by packed cell volume.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1576, THE THERMAL REQUIREMENTS AND TOLERANCE OF KEY ESTUARINE ORGANISMS
J.A. MIHURSKY, Univ. of Maryland, Natural Resources Institute, *College Park, Maryland* 20740

The program will employ temperature as the major variable in monofactorial design and temperature-time and temperature-salinity as variables in poly-factorial design work. Estuarine invertebrates and vertebrates will be tested using three basic approaches: (1) temperature - mortality bioassay, (2) temperature - performance and (3) temperature - metabolic. Steam electric station operational characteristics will be used to influence experimental design.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1577, WATER QUALITY CRITERIA TO PROTECT THE FISH POPULATION DIRECTLY BELOW SEWAGE OUTFALLS
C. TSAI, Univ. of Maryland, Natural Resources Institute, *College Park, Maryland* 20740

The proposed research plan is to establish water quality criteria to protect fish population directly below the sewage outfalls in streams. The criteria will be used as one measurement of sewage pollution assessment and control.

Field investigation will be made at about 120 secondary sewage treatment plant outfalls throughout the State of Maryland during the summers of 1968, 1969 and 1970. At each plant outfall, two stations (one upstream and one downstream, each 300 yards from the outfall) will be designed for determining the water quality (DO, CO2, ammonia, pH, temperature, turbidity, conductivity, nitrite, nitrate, phosphate, and chloride ions) and the fish population (species diversity and fish abundance). The degree of water quality degradation and the degree of fish population depletion by sewage effluents in a stream will be determined from their difference between two stations. Water quality criteria will be established from the relationship between the degree of water quality degradation and the degree of fish population depletion at all plant outfalls studied.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1578, BIOGEOCHEMISTRY OF ESTUARINE ECOSYSTEM WITH EMPHASIS ON HEAVY METALS AND SHELLFISH
J.T. VANDERSLICE, Univ. of Maryland, School of Arts, *College Park, Maryland* 20740

A study of biogeochemistry of estuaries with emphasis on the effects of metal ion and organic pollution on the oyster of the Chesapeake Bay. Selected oyster beds will be analyzed for metal elements and organic compounds in the substrate, silt and fluid portions. Oysters from the same beds will be analyzed for metal content. Mechanisms of retention and storage of metals by the oyster will be studied. A detailed characterization of the lipids in oyster flesh and organs and comparative study of lipid characteristics as functions of age, season and location will be made.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1579, EFFECTS OF SURFACTANTS IN WATER ON BLACKBIRD METABOLISM
M.I. DYER, U.S. Dept. of the Interior, Bureau of Sport Fish. & Wlfe., *Laurel, Maryland* 20810

Objectives: (1) To measure basic and normal metabolic response of blackbirds to a series of different temperature environments. (2) To measure abnormal metabolic responses of blackbirds after treatment with a series of surfactants in water.

Procedures: (1) Assemble physiological apparatus (O2 and CO2 detectors, Beckman Bio-Monitor) to provide metabolic data. (2) Construct empirical avian curve, at least for temperatures of 0.5 degrees, 10 degrees, 15 degrees, and 20 degrees C. (3) Run initial trails non-selective for surfactant, the only criterion being 100 percent effectiveness of wetting qualities of treated Water. (4) Place bird in metabolism suite, monitor for standard response, then treat with surfactant (atomizer system needed). (5) Check CO2 consumption, CO2 production, body temperature parameters before and after treatment. (6) Calculate: R.Q. (use Bio-Monitor); delta T equal (TB - TE minus TE); heat production rate (cal/(gram x hr); and conductance (k cal oird x hr /delta T. (7) Test surfactants as mixtures in water

and as concentrates followed by water treatment-immediately after treatment at intervals during several ensuing days.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1580, COLLABORATIVE RESEARCH IN STRUCTURE, FUNCTION AND EXPORT OF A SALT MARSH
I. VALIELA, Boston University, Graduate School, *Boston, Massachusetts* 02215

This grant supports a study of the structure and function of a New England salt marsh-tidal creek ecosystem subjected to nutrient enrichment by the addition of sewage sludge and chemically defined fertilizers. The consequences of enrichment will be followed in the main structural components of the marsh, particularly primary producers and secondary consumers. These two elements are crucial to the energy exchange between the marshes and adjacent creeks. The research will concentrate on gas exchange in marsh grasses, production of benthic diatoms, populations of benthic animals, especially fiddler crabs and mussels, and growth of fish.

SUPPORTED BY U.S. National Science Foundation

2.1581, WATER RESOURCES POTENTIAL OF AN URBAN ESTUARY
J.J. COCHRANE, Northeastern University, School of Engineering, *Boston, Massachusetts* 02115

An investigation of the physical, chemical and biological parameters pertinent to the development of an urban estuary for recreation and flood control. Specific objectives are: Effects of nitrogen and phosphorous on the development of estuarine algae. Influence of bottom deposits, including nutrients and toxic materials, on the balance of the ecosystem. Determination of background levels of physical, chemical and biological data to ascertain the impact on the estuary of the proposed construction of a flood control detention basin. Development of improved methodology for characterization of an estuarine environment including data collection frequency and computer graphics.

2.1582, PHOSPHATE EXCHANGE WITH SEDIMENTS
W. STUMM, Harvard University, Graduate School, *Cambridge, Massachusetts* 02138

The proposed study is a part of a broad investigation on chemical factors in limnological transformations of phosphate. It is proposed specifically to investigate the kinetics of the reaction CaCO3 plus HPO4 ion yields phosphate substituted CaCO3 (Ca-Phosphate Apatite).

A better knowledge on the distribution of phosphate between the sediments and the overlying waters is relevant for interpreting the eutrophying effect of phosphates introduced into a receiving water. The results of such an analysis should also be of predictive value in establishing whether and how fast the process of eutrophication can be reversed by reducing the introduction of phosphate bearing wastes into the receiving waters.

2.1583, NAVY ENVIRONMENT--SURFACE FILM EFFECTS ON APPARENT INFRARED TEMPERATURES
P. TWITCHELL, New England Aquarium Corp., *Cambridge, Massachusetts* 02139 (N00014-69-C-0380)

Technical Objective: The Navy's ASW Research Program requires examination of the air-sea interface with respect to infrared emission and reflection from the water. Surface pollutants mask the apparent surface temperature and distort ship wake signatures. The thermal energy exchange, and thus thermal structure important in ASW, is also affected by these pollutants.

SUPPORTED BY U.S. Dept. of Defense - Navy

2.1584, INTERACTION BETWEEN MARINE ORGANISMS AND OIL POLLUTION
P.M. FYE, Woods Hole Oceanographic Inst., *Woods Hole, Massachusetts* 02543

I. Marine hydrocarbons derive in part from living organisms and in part from pollution. We plan to establish sensitive criteria to distinguish hydrocarbons from either source. This knowlege is essential if we are to measure in the oceans the spread of the true pollutants and not of the ubiquitous natural hydrocarbons.

II. Many stable pollutants, especially hydrocarbons, pass through the marine food chain with little alteration but often with a rise in concentration. We plan to study the persistence and accumulation by marine organisms, especially human food, of objectionable and hazardous compounds derived from pollution.

III. Natural organic compounds in the sea play an important ecological role as stimuli in the attraction of the sexes, in the finding of food and in short and long distance migration. Marine pollution is likely to interfere with many of these processes. Because of the extreme sensitivity of the organisms to these stimuli, such interference may be more subtle and still have a more catastrophic long term effect than the gross toxicity of bulk pollution. We plan to study the extent to which marine pollution interferes with these processes and the concentrations which are harmful.

2.1585, NAVY ENVIRONMENT - ENVIRONMENTAL EFFECTS OF DEEP WATER ORDNANCE DISPOSAL
B.H. KETCHUM, Woods Hole Oceanographic Inst., *Woods Hole, Massachusetts* 02543 (N00014-66-C0241)

Technical Objective: Evaluation of the environmental effects of Navy ordnance disposal in the deep ocean is essential to prevent inadvertent pollution of the marine ecosystem. Woods Hole Oceanographic Institution is providing investigative and consultative assistance to the US Naval Ordnance Laboratory in determining the ecological consequences of deep ocean ordnance disposal off the northeast coast of the United States.

SUPPORTED BY U.S. Dept. of Defense - Navy

2.1586, COLLABORATIVE RESEARCH IN STRUCTURE, FUNCTION AND EXPORT OF A SALT MARSH ECOSYSTEM
J.M. TEAL, Woods Hole Oceanographic Inst., *Woods Hole, Massachusetts* 02543

This grant supports a study of the structure and function of a New England salt marsh-tidal creek ecosystem subjected to nutrient enrichment by the addition of sewage sludge and chemically defined fertilizers. The consequences of enrichment will be followed in the main structural components of the marsh, particularly primary producers and secondary consumers. These two elments are crucial to the energy exchange between the marshes and adjacent creeks. The research will concentrate on gas exchange in marsh grasses, production of benthic diatoms, populations of benthic animals, especially fiddler crabs and mussels, and growth of fish.

SUPPORTED BY U.S. National Science Foundation

2.1587, ENVIRONMENTAL CHANGES IN LAKE ERIE
J.F. CARR, U.S. Dept. of Commerce, Natl. Marine Fisheries Service, *Ann Arbor, Michigan* 48107

Lake Erie has experienced major changes in the benthos and fish populations. Analyses of physicochemical data show that concentrations of most major ions have increased significantly, very low dissolved oxygen concentrations occur during the summer, and mean annual water temperatures have increased. Present studies are directed toward documenting the extent of change in the benthos and studying the factors which result in the oxygen depletion of the hypolimnetic waters. Laboratory and field studies are being made of the exchange of nutrients and the oxygen demand at the mud-water interface.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1588, LONG-TERM EFFECTS OF PESTICIDES ON AQUATIC INVERTEBRATES
M.E. BENDER, Univ. of Michigan, School of Public Health, *Ann Arbor, Michigan* 48104

The long-term effects of parathion and endrin exposure to aquatic invertebrates are being studied under continuous flow conditions. Test organisms include: the stonefly Acroneuria, the caddisflies hydropsyche and Chimarra, the dobsonfly Corydalus and crustaceans Asellus and Gammerus, measurement of effects is being evaluated by: mortality rates, growth, time of molting, success of emergence and reproduction success of crustaceans.

The acute and chronic effects of the hydrolysis products of malathion, parathion, and sevin are also being studied.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1589, EFFECT OF WATER TEMPERATURE AND/OR DISSOLVED OXYGEN REQUIREMENTS ON SELECTED MOLLUSKS

H. VANDERSCHALIE, Univ. of Michigan, Graduate School, *Ann Arbor, Michigan* 48104

Eight species of gastropods representing a variety of habitats, ability to survive within several ecological situations, susceptibility to pollution, and significance in the food chain have been selected for study: Physa gyrina, Lymnaea stagnalis appressa, L. emarginate, Helisoma trivolvis, H. campanulatum, Goniobasis livescons, Pleurocera acuta, Amicola limosa.

The temperature tolerance for short periods of time will be determined for the eight species listed above. Three principal factors of several are involved; tolerance to sudden temperature changes, acclimation rates, and upper physiological limits. These three factors will be tested in a manner to separate their importance. An animal migrating or swimming down a river is subject to sudden temperature change at the mixing zone; sensitivity will be tested in this parameter. Rate of acclimation tests are important for ascertaining how fast a temperature changes without adverse effect on the animal, and upper physiological limit ascertains maximum limit of temperature change without death.

Further growth rate over a wide range of temperature changes, freezing, to barely possible survival limits will be investigated. Thus, rate of growth at optimum temperature will be determined. Finally, studies will include the effects of various elevated temperatures on the reproduction of the snail.

This contract was started Fiscal Year 1968-69 and is scheduled to end 1971-72. Quarterly reports are to be submitted to the contract officer in order to keep him posted on the progress of the study. All raw data will be furnished in a final report so that no data are lost for future reference and study.

2.1590, ECOLOGY OF PESTICIDES IN AN AQUATIC ECOSYSTEM

R.C. BALL, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00961)

OBJECTIVE: Develop methods of evaluating effects of low levels and chronic input of pesticides in an aquatic habitat. Study of pathways and mechanisms of movement through the aquatic ecosystem, and identification of biotic effects at each trophic level.

APPROACH: The precision, reliability, and specificity of 'stress' analysis technic tested on insecticides in two artificial streams. Criterion will be changes in the mobile fraction of the plasma proteins in fish. Study movement of the toxic materials from the soil into the ponds and follow through the organisms that constitute the food chain leading to game fish.

PROGRESS: The fate of DDT was studied in a productive farm pond and in three artificial pools. The effect of fish and food organisms on the degradation and distribution of DDT was assessed in the pools by placing both trophic levels in one pool, just food organisms in another pool and fish without food organisms in a third pool. DDT applied to the experimental units was lost from the units, apparently by codistillation with evaporating water. DDT in the water was rapidly taken up by the flora, fauna and sediments. DDT deposited on the bottom was degraded to DDD. Both DDD and DDT were recycled back into the water from the bottom. Invertebrates and fish degraded DDT and DDE. Biological transfers of DDT facilitated its degradation to DDE. Increasing the biological productivity of the lentic ecosystem appeared to promote DDT degradation to DDE. The concentration of DDT-R (DDT, DDD and DDE) persisting in the flora and fauna was mediated by the concentration of DDT-R in the water. DDT-R was concentrated from the water about 1 x 10 times by algae, 1 x 10 times by invertebrates and 1 x 10 times by lean fish.

SUPPORTED BY U.S. Dept. of Agriculture

2.1591, TOXIC ACTION OF WATER SOLUBLE POLLUTANTS ON FRESHWATER FISH

P.O. FROMM, Michigan State University, School of Medicine, *East Lansing, Michigan* 48823

Fish subjected to chronic low level stress (hexavalent chromium) and forced exercise exhibited a transitory increase in plasma cortisol which returned to control levels after one week exposure. Animals treated with exogenous cortisol by implanting pellets in the body cavity had plasma cortisol levels of over 100 micrograms. Fasted fish so treated had elevated liver glycogen and excreted more waste nitrogen than controls. Plasma glucose was not elevated. Animals similarly treated but fed during the experimental period had liver glycogen stores and nitrogen excretion rates similar to controls. A seasonal variation in plasma cortisol levels of untreated trout was found.

Rainbow trout were placed in solutions of ammonium chloride containing 0,1,3,5 and 8 micrograms ammonia (total)/ml. After 24 hours' exposure the blood levels for total ammonia showed a direct linear correlation with ambient ammonia and ranged from 38 to 71 micrograms/ml. Expressed in terms of non-ionic ammonia (NH_3): fish exposed to 0 to 1 micrograms ml had blood levels which ranged from 0.06 to 1.3 micrograms ml. The daily excretion of total waste nitrogen showed an inverse relationship with starting ambient levels of ammonia as did the data for excretion of ammonia nitrogen. The relatively greater decrease in ammonia nitrogen excretion nitrogen over total nitrogen excretion in fish exposed to the higher concentrations of ammonia suggests that excretion of other nitrogenous compounds occurred to partially compensate for decreased ammonia nitrogen excretion.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1592, PHYSIOLOGIC RESPONSE OF AQUATIC ORGANISMS TO POLLUTANTS

P.O. FROMM, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00122)

OBJECTIVE: Determine physiological cause of death in aquatic animals most susceptible to pollutants, establish the symptoms of sublethal amounts of pollutants. Identify responses which have value as diagnostic symptoms of pollution toxicity. Determine validity of findings in predicting population changes in habitats subjected to pollution.

APPROACH: Kinetics of surface binding of chromium to cells made and studies of metabolic respones of fish. Investigation of pathway(s) of excretion by fish of two radionuclides (Cr and I) permeability of fish skin.

PROGRESS: Studies using the isolated-perfused trout gill preparation have indicated that when perfused with Ringer solutions having sodium concentrations less than normal plasma levels there was a net uptake of sodium from the bath solution. Perfusion fluid sodium level and epinephrine both appear to control the rate of sodium uptake by isolated gills. Experiments with various inhibitors indicated that sodium uptake is an oxidative metabolism dependent and an ATP dependent system which may be independent of rate and pattern of fluid flow through the gill. In gills exposed to dieldrin, rotenone and MS-222 (tricainemethanesulfonate) flow rates in muL/min dropped significantly, whereas exposure to methoxychlor had no effect. Histological sections of india ink perfused gills exposed to these test chemicals have not yet been completely evaluated and results will be reported later. Studies of the effect of these same chemicals on sodium transport by isolated gills were made using flame photometric analytical procedures but the results were generally unsatisfactory. New studies using radiosodium and radioiodine labeled protein are now underway and reliable data should be obtained. Studies of the effect of ammonia on nitrogen excretion by intact fish have been terminated. When ambient ammonia was increased total-N and ammonia-N excretion decreased, excretion

of urea remained relatively constant and the excretion of waste protein-N showed a slight increase. Some five per cent of the total waste-N excreted remained unidentified.

SUPPORTED BY U.S. Dept. of Agriculture

2.1593, EFFECTS OF LIMNOLOGICAL FACTORS ON UPTAKE OF 137CS BY FISH

N.R. KEVERN, Michigan State University, Institute of Water Research, *East Lansing, Michigan* 48823 (AT(11-1))

Limnological factors that directly or indirectly influence the uptake of 137Cs by fish are being investigated in six contrasting lakes. The factors include concentrations of 137Cs, stable cesium and potassium, and the conductivity and alkalinity. The relationships will be determined by multiple regression analysis. Analyses are being made on samples of largemouth bass and water from each lake and will allow demonstration of the importance of the specific activity of the water on the uptake of 137Cs. Very low concentrations of stable cesium in freshwater dictate the development of methods to concentrate water samples. Investigations on this will include removal by and elution from exchange columns using cobalt ferrocyanide compounds. The final analytical step for cesium is by flame emission techniques. The influence of trophic position on the accumulation of cesium 137 is being studied also. Samples of plants, invertebrates and several fish species in a trophic level series will be collected from a single lake. These samples will be analyzed for 137Cs and potassium. Analysis of variance will be used to test for differences in 137Cs concentrations among trophic levels. The overall objective is to gain sufficient knowledge to allow prediction of maximum concentrations of 137Cs in food fishes when given estimates of radio-nuclide inputs to the water.

SUPPORTED BY U.S. Atomic Energy Commission

2.1594, AN EVALUATION OF WIDELY USED HERBICIDES ON AQUATIC PLANTS, FISH AND FISH-FOOD ORGANISMS

V.A. KNUDSON, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00959)

OBJECTIVE: Assess the influence of total alkalinity, pH and temperature of the water on the effectiveness of several widely used herbicides. Test the effect of weed control by chemical means on fish- food organisms. Evaluate fertilization as a method of controlling higher aquatic plants.

APPROACH: Preliminary work in the laboratory will include study of influence of water quality on effectiveness of various herbicides. Toxicity of herbicides to fish will be studied in conjunction with the laboratory, experiments. While some fertilization studies can be done in the laboratory, the major effort here will be in farm ponds and small lakes.

PROGRESS: Bioassays were run with two genera of cladocerans, Simocephalus sp. and Ceriodaphnia- sp., an ostracod, and Vivaparus purpurea, a large snail. Herbicides tested included copper sulfate, sodium arsenite, diquat, silvex, 2,4-D, endothal, and Hydrathal-47. The tests generated several conclusions: snails were generally unaffected by all herbicides tested except for copper sulfate, while cladocerans and ostracods were particularly susceptible to H-47, copper sulfate, and sodium arsenite at all levels tested; copper sulfate, even at 0.15 ppm, proved lethal to most organisms tested and should be studied in greater detail, since it apparently is used at toxic levels in the environment. Endothal, silvex, 2,4-D, and, in most cases, diquat, appeared to be relatively harmless to the organisms tested.

SUPPORTED BY U.S. Dept. of Agriculture

2.1595, MONITOR FISH POPULATIONS IN THE VICINITY OF THE PALISADES NUCLEAR POWER PLANT SITE ON LAKE MICHIGAN

M.H. PATRIARCHE, State Res. & Dev. Division, *Lansing, Michigan* 48926

Objectives: Determine whether or not the heated effluent of about 1,000 cfs from this power plant will have pronounced effects on the fish population in the vicinity of the plant, with respect to species composition, abundance, and growth.

Procedures: For 2 years prior to the start of plant operations (spring of 1970) and 3 years thereafter, gill nets will be fished for two 24-hour periods (longer intervals if weather interferes) four times a year. These sampling periods coincide with a limnological study plan carried on by a private consultant, and occur in mid-May, late June, late August, and mid- October. Approximately 1,000 feet of gill nets of assorted mesh sizes are fished in four gangs at eight stations located 1/2 and 1 mile out from the plant site, on transects radiating out from shore. Water depths range from 20 to 40 feet. All fish captured are measured and counted; many are scale sampled, sexed, and weighed. Shoreline seining (day and night) with a 125-foot bag seine will be done when conditions permit. Also, fish will be collected by trawling when the schedules of either the Department research vessel 'Steelhead' or the Bureau of Commercial Fisheries vessel 'Cisco' permit. The field data will be used to determine species and age composition, catch per unit of effort indices, and seasonal growth rates.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1596, MONITORING FISH POPULATIONS IN THE VICINITY OF THE PALISADES NUCLEAR POWER PLANT SITE

M.H. PATRIARCHE, State Res. & Dev. Division, *Lansing, Michigan* 48926

Project and Job Objectives: To determine if there is a pronounced change in the species composition of the fish stocks and their growth rates after heated plant discharges enter Lake Michigan.

With the advent of many nuclear power plants on the Great Lakes, information is needed on the effects on the fish populations of the heated discharges into these large cold bodies of water. Activities such as fishing (both commercial and sport) and stocking salmonids might be affected by fish reactions to temperature and other possible environmental changes. Inasmuch as Consumers Power Company, the owner of the plant, is financing a 4-year limnological study and the Michigan Department of Natural Resources is furnishing a vessel and manpower for same, it was decided to also sample the local fish population during these surveys to detect any gross changes that might occur.

Procedures: Under one job, population sampling will be done concurrently with the seasonal limnological surveys. Gill netting, shorelines seining (in summer), and trawling (by the Bureau of Commercial Fisheries vessel 'Cisco') will be done before and after the plant goes into operation. Seasonal and annual data on population structure and fish growth will be compared.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1597, CHRONIC EFFECTS OF HEAVY METALS ON FISH

R.W. ANDREW, U.S. Dept. of the Interior, Federal Water Quality Admin., *Duluth, Minnesota* 55804

The overall objective of this work is to develop analytical and toxicological techniques for relating the chronic effects of heavy metals and heavy metal wastes to observable short-term metabolic and physiological effects. The acute, subacute, and chronic effects of Cr, Cu, Cd, and Zn will be studied with Brook Trout, Yellow Perch, and for Bluegills as possible test species. Emphasis will be placed on the effects of the metals on the respiratory and reproductive systems, growth rates, and overall production efficiency of the fish. Tracer and radiotracer techniques will be used to determine modes of metabolism (intake/disposition/excretion) and physiological effects of one or more of the metals. Ultimately, attempts will be made to correlate the chronic physiological and toxicological effects with measurable short- term (acute) effects.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1598, MULTIPLE SCLEROSIS AND THE QUALITY OF DRINKING WATER

M. ALTER, U.S. Veterans Administration, Hospital, *Minneapolis, Minnesota* 55417

Epidemiologic evidence is being collected and analyzed relating various parameters of environmental sanitation to the distribution of multiple sclerosis. So far, almost all data collected

support the hypothesis that a positive correlation exists between the quality of environmental sanitation and the frequency of MS. It has been shown that a) communities which are technologically advanced but have poor sanitation have a low rate of MS, b) socio-economically disadvantaged individuals (Negroes) have a lower rate of MS than socio-economically favored individuals (Caucasians) living in the same area, c) groups reared in an area where sanitation is improving tend to have an increase in frequency of MS as compared to immigrants to the same region reared in less sanitary environments, d) communities having a frequency of MS different from what would be expected on the basis of their geographic latitude, are not 'discrepant' if the sanitation in the community is taken into account, e) the distribution of sanitation parameters such as quality of drinking water, sewage disposal, crowding, tuberculosis, correspond well with the distribution of deaths due to MS.

If the hypothesis is valid that sanitation and MS are directly 'linked,' it might mean that the agent causing MS is transmitted via contaminated water or food. As was the case in poliomyelitis, in areas with poor sanitation, an agent was transmitted early in life and individuals infected then developed immunity. Individuals in sanitary environments were affected later and developed clinical signs of the disease. A similar mechanism might be operating in MS.

SUPPORTED BY U.S. Veterans Administration

2.1599, POLLUTION AND THE ECOLOGY OF NEAR-SHORE PERIPHYTON OF LAKE SUPERIOR
T.A. OLSON, Univ. of Minnesota, School of Public Health, *Minneapolis, Minnesota* 55455

Representative areas of the North Shore and other adjacent waters will be examined for the purpose of characterizing the periphyton which prevails in shallow water areas and at the shore-water interface: for the purpose of comparison, concurrent samples of periphyton will be collected from deeper waters. In addition, simultaneous field and laboratory experiments will be carried on to ascertain the growth response of the periphyton community as affected by contamination or enrichment of the water. Flow-through, temperature controlled photosynthetic units used in earlier pigment studies on deeper water periphyton will be utilized for this work. Certain in situ experiments dealing with controlled eutrophication are also planned. Estimates of productivity and growth rates will be made and reported on the basis of dry and ash-free dry weight.

2.1600, CONTROLLED TEMPERATURE REGIMES IN OUTDOOR EXPERIMENTAL PONDS
E. SILBERMAN, Univ. of Minnesota, School of Engineering, *Minneapolis, Minnesota* 55414

The Water Quality Laboratory of the Federal Water Pollution Control Adminstration located at Duluth, Minnesota, proposes to build and operate a number of outdoor experimental ponds for the study of aquatic life under the effect of variable water temperatures. The ponds would be located near the electric power generating plant presently under construction near Monticello, Minnesota, and owned by Northern States Power Company. Waste heat from the plant and local groundwater supplies would be available for establishing controlled temperature regimes in the ponds. The ponds are to represent natural conditions insofar as this is compatible with maintaining the desired experimental temperature regimes.

Personnel of the Heat Transfer Laboratory, Department of Mechanical Engineering, University of Minnesota, are to assist in the study of the means whereby artificial heating (or cooling) may be applied to maintaining predetermined temperature regimes in large outdoor ponds. The objective of the study will be to devise a method whereby the requirements for temperature control in the experimental ponds of the Water Quality Laboratory can be met as nearly as possible. A secondary objective will be to establish modified requirements for the ponds if certain of the preliminary requirements turn out to be impracticable.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1601, SECONDARY PRODUCTION IN RUNNING-WATER ECOSYSTEMS
T. WATERS, Univ. of Minnesota, Graduate School, *Minneapolis, Minnesota* 55455

This project is concerned with the study of secondary production in streams, including production rates, growth and survival rates, and quantitative life-history information for stream invertebrate animals primarily. The emphasis on invertebrates is significant, because it is this group that is the most sensitive to the quality of the aquatic habitat and to environmental disturbances. Studies will be made in streams of eastern Minnesota, including both field sampling and laboratory experiment. Production rates will be determined according to the growth method of Ricker and Allen, for which instantaneous growth rates and field standing crops are required. Growth rates will be determined from laboratory culture of invertebrates in running-water aquaria and small laboratory streams at normal season-specific water temperatures. Additional growth information for confirmation will be derived from size-frequency analyses of bottom samples. The new Hynes-Coleman-Hamilton procedure of estimating production rate will be tested; turnover ratios will calculated for all species and streams.

Aquatic ecologists in the past have focused most attention on lakes, large reservoirs, and the oceans. Relatively little effort has been applied to the running-water ecosystems, except that of a descriptive nature. This resource is delicate and easily disturbed, and recovery is often difficult and slow. Therefore, the continued viability of streams as sources of domestic water supply, waste dispersal, recreation, and natural beauty, will depend on intensive management, the expected significance of the research is in providing knowledge that will permit such management on a sound basis.

SUPPORTED BY U.S. National Science Foundation

2.1602, MISSISSIPPI RIVER ECOLOGY ASSOCIATED WITH HEATED POWER PLANT EFFLUENT
A.J. HOPWOOD, Saint Cloud State College, Graduate School, *Saint Cloud, Minnesota* 56301

Construction of a large power plant on the Mississippi River near Monticello, Minnesota, is scheduled for completion in February, 1970. Heated water will be discharged from the plant during operation causing changes in the environment with subsequent alterations in aquatic life. The study described herein is designed to determine existing ecological conditions in the Mississippi River before operation of the plant and to monitor environmental changes due to thermal discharge from the generator.

The above purpose can best be served by attainment of the following objectives: A. Prior to operation, February, 1970: 1. Determine existing physical and chemical factors of water quality; 2. Determine existing species, and temporal and seasonal abundance; 3. Determine general physical condition, food habits, life cycles & energy relations of species in the river ecosystem. B. During operation: 1. Compare physical and chemical water quality with that which was present before plant operation; 2. Compare species structure and abundance with data collected prior to operation; 3. Observe physical condition, food habits, life cycles and energy interactions of all species.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1603, EFFECT OF HEATED DISCHARGE WATER FROM POWER GENERATING PLANT ON FISH POPULATIONS & FISHING IN LAKE ST. CROIX (ABBREV)
H. KROSCH, State Div. of Game & Fish, *Saint Paul, Minnesota* 55101

Objectives: To collect, compile and evaluate information about fish populations and fishing success in the vicinity of the Allen S. King power generating plant at Oak Park Heights for two years prior to and three years after the plant goes into operation to determine the effects of heated discharge water on fish and

fishing in Lake St. Croix. This information will be used to help formulate regulations governing operations of other power plants.

SUPPORTED BY Minnesota State Government - Saint Paul

2.1604, DOMESTIC WATER PROBLEMS AS RELATED TO TEXTILES

S. DAVISON, Univ. of Minnesota, Agricultural Experiment Sta., *Saint Paul, Minnesota* 55101 (MIN-20-095)

OBJECTIVE: Investigate the effect of water of various mineral content on fabrics composed of cotton, chemical fibers or blends. Study the problems arising from the methods of laundering used by a selected group of homemakers in water problem areas.

APPROACH: State Extension specialists will assist in selection of water problem areas and Home Agents will assist in choosing homemakers participating in study. The garment selected will be worn and laundered by homemakers with their other apparel. They will be returned to laboratory at specified intervals for evaluation by nondestructive measures. Information on washing methods, equipment, agents, water supply, etc. will be obtained. Laboratory investigation will parallel wear study as a means of determining how's and why's of problems encountered and as a control of work underway at cooperative stations. As garments are withdrawn evaluation will include such measures as stiffness, residual strength, elongation, weight, thickness, and dimensional stability.

PROGRESS: Through the cooperation of the Agricultural Extension Services polyester cotton fabrics, with and without permanent press, have been laundered with family white wash loads from one to 25 times. There are 20 participants in a hard water area of each state. Mrs. Ruth Kent, Home Economics Agent in Itasca County, has assisted in supervision of the Minnesota study. Swatches were withdrawn at specified intervals. Factors held constant were the type of detergent, and type of washer (top loading). Water samples were analyzed for hardness minerals and iron content. Using paper thermometers enclosed in glass, temperature of wash water was obtained periodically. Reflectometer readings to determine whiteness or grayness are in progress. Swatches of the same fabric as that used by the participants have been artificially soiled. These are being laundered in a controlled laboratory study using four levels of water hardness, three water temperatures, two types of detergent (anionic and non-ionic) and five concentrations.

SUPPORTED BY U.S. Dept. of Agriculture

2.1605, EFFECT OF PAPER FIBER WASTES ON FISH EGGS AND JUVENILES

L.L. SMITH, Univ. of Minnesota, School of Agriculture, *Saint Paul, Minnesota* 55101

Suspended wood fiber is to be tested for its effects on fish eggs, fry and fingerlings. Effects of wood fiber mats in Rainy River on fish and invertebrates will be tested. Decomposition products of wood fiber mats will be tested in laboratory. Effect of Sphaerotilus natans on fish eggs and fry is to be tested. Deleterious effects of low oxygen levels in connection with fiber decomposition products will be determined.

SUPPORTED BY U.S. Dept. of Interior - Wtr. Qua. Adm.

2.1606, EFFECT OF WATER POLLUTANTS AND WATER QUALITY ON EARLY LIFE HISTORY AND POPULATION DYNAMICS OF MINNESOTA FISHES

L.L. SMITH, Univ. of Minnesota, Agricultural Experiment Sta., *Saint Paul, Minnesota* 55101 (MIN-17-076)

OBJECTIVE: Determine the influence on fish production of various water pollutants of industrial and domestic origin; specifically, what such materials as H(2)s, detergents, paper mill wastes and similar materials have on growth rate, fecundity, and survival of fish. Fish food organisms are also included in investigations.

APPROACH: Field observation in polluted areas are made to determine limits of major parameters such as temperature, O(2) pollutant levels and fish survival. Laboratory bioassays, long-term tests at sublethal levels of various materials, and fecundity tests will be made in the laboratory under controlled conditions to separate out effects of various factors and to define subtle lont-term effects of pollutants that will influence level of annual harvestable crop of fish.

PROGRESS: This project has been devoted during the present calendar year to long term studies of low level hydrogen sulfide concentrations and their effect on various life history phases of five species of fish. These studies, which were in progress for the entire period, have examined growth, spawning characteristics, and survival of fathead minnows, walleye pike, goldfish, bluegills and suckers. It has been determined that sublethal levels of hydrogen sulfide reduce growth, inhibit spawning, and inhibit food conversion efficiency on these species. It is planned that these studies will be continued through at least two full life history cycles. Short-term acute bioassay tests have been run on these species to determine the relationship of the TLM values to demonstrate deleterious effects of long term exposure at lower levels.

SUPPORTED BY Minnesota State Government - Saint Paul

2.1607, HEMATOLOGY OF FISH

B.A. FISCHER, Univ. of Southern Mississippi, School of Arts, *Hattiesburg, Mississippi* 39401

Study of whether there is a significant difference in the hematology of fishes from polluted and nonpolluted streams in the State of Mississippi.

SUPPORTED BY University of Southern Mississippi

2.1608, WATER AND SEDIMENT, SUPPLY AND ACCUMULATION IN THE ESTUARY, ST. LOUIS BAY, MISSISSIPPI

C.M. HOSKIN, Univ. of Southern Mississippi, School of Arts, *Hattiesburg, Mississippi* 39401

Texture, origin and sites of sedimet accumulation will be studied for the Wolf and Jordan Rivers and Bay St. Louis estuary. Sediment accumulation in estuaries has multiple impact because of the strong control on distribution of aquatic creatures of commercial importance to man and because of potential interference with man's exploitation of estuaries in water use, recreation and industry.

SUPPORTED BY University of Southern Miss. - Hattiesburg

2.1609, A SURVEY OF THE VERTEBRATES OF THE PEARL RIVER RESERVOIR

J.P. MCKEOWN, Millsaps College, Undergraduate School, *Jackson, Mississippi* 39210

Population studies of the relative densities of the vertebrates in the Pearl River Reservoir are being made. The effects of various pollutants on natural populations are being determined.

SUPPORTED BY Millsaps College

2.1610, A SYSTEMS APPROACH FOR THE STUDY AND CONTROL OF FACTORS AFFECTING WATER POLLUTION

R. ANOUR, Mississippi St. University, School of Engineering, *State College, Mississippi* 39762

The proposed research plan is directed toward using a systems approach technique for the determination of various activities and their effects on water pollution.

The main purpose of these investigation is to build a systems approach including all ecosystem pollution factors and to find through operational analysis the interrelationships between or among these factors. This could be the first step toward optimization of water pollution problems as a whole instead of suboptimization of each individual pollution problem.

The proposed plan will be done in three stages: 1. General review of the literature for the pollutants which enter the main stream from point sources and dispersed sources. 2. Field investigations of sources, type of pollutants and their associated risks in a selected, small river basin. 3. Development of a general systems approach through mathematical modeling and operational analysis.

2.1611, THE EFFECT OF SALINITY ON THE OXIDATION OF HYDROCARBONS IN ESTUARINE ENVIRONMENTS

L.R. BROWN, Mississippi St. University, Graduate School, *State College, Mississippi* 39762

It is known that petroleum products are adsorbed on the surfaces of various materials including silt and sand and find their way to the bottom of bodies of water. Ultimately, these materials are utilized by microorganisms, but very little is known about the rate of decomposition, the products formed from their utilization, or the effect of the environment on the microbial hydrocarbon utilization.

The overall objective of this proposal is to study the effect of salinity on the oxidation of hydrocarbons in estuarine environments. More specifically, studies will be conducted to determine (1) the effect of various salinities on the aerobic utilization of petroleum products, (2) the effect of salinity on the anaerobic decomposition of petroleum products, and (3) the microflora that predominate at various salinities.

2.1612, ENVIRONMENTAL STUDIES ON THE MISSISSIPPI RIVER

W.T. MCKIE, Mississippi St. University, School of Engineering, *State College, Mississippi* 39762

A study of the effects of the discharge of heated effluents on the aquatic life of the Mississippi River. A mathematical model for the thermal energies as related to the electrical load demand, the river conditions, and the expected water temperatures will be developed.

SUPPORTED BY Mississippi Power & Light Co. - Jackson

2.1613, THERMAL GRADIENTS ASSOCIATED WITH DISCHARGE OF HEATED EFFLUENTS

A. SHINDALA, Mississippi St. University, School of Engineering, *State College, Mississippi* 39762

Although there has been a considerable amount of work on the qualitative effects of heated waters on aquatic life and some qualitative work on thermal gradients, there is relatively little published information on the analysis of hydraulic factors and their influence on thermal gradients. The writer does not know of any successful attempt at a generalized method for the prediction of thermal gradients.

It is the purpose of this proposed study to gather and analyze prototype data on thermal gradients in the receiving waters and to relate those gradients to the hydraulic characteristics of the entering and receiving streams. A procedure for the prediction of thermal gradients which result from the entry of heated effluents from thermal power plants into natural streams will be developed.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1614, DETERMINATION OF AQUATIC ECOSYSTEM RESPONSE TRENDS RESULTING FROM MAN-IMPOSED ENVIRONMENTAL STRESSES

J.W. KEELEY, U.S. Army, Corps of Engineers, *Vicksburg, Mississippi*

Technical Objective: Determine functional relations between the biotic and abiotic elements of select aquatic ecosystems. In particular, the research is directed toward the development of a capability for predicting the response trends of ecosystems that result from environmental stresses imposed by man's activities. Results of this study may be used to plan military and construction activities that will not adversely affect the ecological environment.

SUPPORTED BY U.S. Dept. of Defense - Army

2.1615, IMPACT OF CORPS OF ENGINEERS CONSTRUCTION ACTIVITIES ON THE ECOLOGICAL ENVIRONMENT

J.W. KEELEY, U.S. Army, Corps of Engineers, *Vicksburg, Mississippi*

Technical Objective: The objective of this work unit is to provide consultant services and to define areas and capabilities for environmental research as related to the U. S. Army Engineer Waterways Experiment Station in particular and the U. S. Army Corps of Engineers in general with emphasis on the extreme importance of developing an in- house capability for a coordinated systems approach to meet military as well as civic needs. Army interests in ecology include but are not limited to the conduct of military and construction activities so that the ecological environment will not be adversely affected. Military reservations together with theaters of operations encompass all aspects of ecology such as water resources, land and forests which together contain all species of fish and wildlife.

SUPPORTED BY U.S. Dept. of Defense - Army

2.1616, EFFECTS OF RECENT AND PAST PHOSPHATE FERTILIZATION ON THE AMOUNTS OF PHOSPHORUS PERCOLATING THROUGH SOIL PROFILES INTO SUBSURFACE WATERS.

R.W. BLANCHAR, Univ. of Missouri, School of Agriculture, *Columbia, Missouri* 65201

The proposed work is a laboratory investigaton of the phosphorus chemistry of two similar soil profiles. One profile has received no fertilizer phosphate and the other has been maintained at a phosphate level judged adequate for maximum crop production since 1889. The profiles will be sampled to a depth of nine feet and divided into appropriate horizons.

The chemical characteristics of the soil profile which influence the solubility of phosphorus will be determined. Total, organic, inorganic, aluminum, calcium, iron, occluded, available, and water soluble phosphates in the profile will be measured. The kinetics of phosphate adsorption and equilibration with the water phase will be measured. Equilibrium extracts will be evaluated in terms of mineral components responsible for phosphate solubility.

A model will be developed and tested to estimate the amount of phosphate which will percolate through heavily and non-fertilized soil profile. This information will be related to chemical properties of the soil profile and to predictions of the probability of percolation conditions for Missouri soils. These data will act as a guide to predict the probable contribution of fertilizer level to the effectiveness of phosphate from farm fields in terms of water pollution.

2.1617, RECOVERY FROM ACID POLLUTION IN FOUR STRIP-MINE LAKES

R.S. CAMPBELL, Univ. of Missouri, Graduate School, *Columbia, Missouri* 65202

The purpose of this research is to determine the successional changes in strip-mine lakes during recovery from acid pollution. This series of lakes created by strip-mining in 1919-21 show widely divergent biological and chemical characteristics which are related to differences in acidity ranging from pH 3.0 to pH 8.6. Total acidity ranges from 5090 to 98 mg/liter $CaCO_3$.

These lakes were first investigated in 1940-41 and again in 1949- 50. The present study dates from 1960. Successional changes are therefore documented within individual lakes and inferred from lake to lake as the acid climate is slowly altered.

In addition to seasonal physical, chemical and biological investigations, special effort is directed toward: (1) Evaluation of chemical stratification, and of the iron (Fe II - Fe III) complex; and (2) Measurement of water quality, of comparative primary and secondary production of community metabolism and of energy flow.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1618, THE EFFECTS OF HERBICIDES, PESTICIDES, AND FERTILIZERS ON THE OPTICAL PROPERTIES OF WATER

M.R. QUERRY, Univ. of Missouri, Water Resources Research Ctr., *Columbia, Missouri* 65201

A study is proposed to determine the effects of herbicides, pesticides, and fertilizers on water's capacity to reflect and absorb electromagnetic radiant flux.

The objectives of the project are: (1) The measurement of the reflectance and transmittance of water solutions of herbicides, pesticides and fertilizers with infrared radiant flux. (2) The computation of the optical constants, i.e. the index of refraction and the extinction coefficient from the reflectance and transmittance data. (3) The computation of the absorptance and reflectance of radiant energy for these solutions, and to relate these results to possible long range changes in the thermodynamic equilibrium of rivers, lakes, and coastal waters. (4) The further study of the intermolecular interaction of solutes with the water substance.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1619, THE EFFECT OF WATER TEMPERATURE ON ECOLOGICAL PROCESSES IN A RESERVOIR RECEIVING HEATED WATER

A. WITT, Univ. of Missouri, School of Arts, *Columbia, Missouri* 65202

Thomas Hill Reservoir is subject to thermal loading in one of its two lower arms. This provides control and experimantal arms in which environmental alterations, due to thermal loading, can be studied. Acid mine drainage occurs in the upper end of the lake.

Field investigations will determine the effects of thermal loading on: 1. Photosynthetic rates of planktonic algae. 2. Rate of accumulation of organic matter by 'Aufwuchs'. 3. Community metabolism. 4. Temperature effect on water quality. 5. Contribution of limited acid inflow to the ionic compositions of the water. 6. Effect of heated water on benthos. 7. Growth rates of young-of-the-year and yearling fishes. 8. Culture of fishes in floating baskets in the heated water. 9. Movement of fishes in response to heated water.

A laboratory will investigate: 1. Temperature tolerances of fishes. 2. Rates of ingestion, food conversion efficiencies and growth of channel catfish under controlled temperatures. The results of this study will lead to a better understanding of the alteration of environmental processes due to heat and acid inflow, and how it may be managed for the benefit of man.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1620, HARVEST OF FISH IN THOMAS HILL RESERVOIR

W.D. HANSON, State Dept. of Conserv., *Jefferson City, Missouri* 65102

Objectives: To determine the fishing pressure, rate of success, and the hook-and-line yield by season. To determine what influences a warmwater discharge from a power plant has upon angling success and seasonal angler-use patterns.

Procedures: One job-trained creel census clerk will conduct a census on the entire reservoir on a one-half time basis. He will count boat and shore fishermen twice daily, according to a prearranged schedule, with the counts being started at opposite ends of the census area alternately. The lake will be divided into five areas, each area being treated as a separate unit for later comparative purposes. During the remainder of the working day, the clerk will contact fishermen both on shore and in boats in each of the five areas. Only those creels inspected by the clerk will be reported. In addition, the clerk will obtain lengths, scales and stomachs for designated species as the need arises. A record of air and water temperature, Secchi readings, and lake levels will be kept daily for each area. When tagging operations are conducted on the lake, the clerk will solicit the cooperation of anglers, Conservation Agents and local people for tag return information.

Calculations of species composition of the catch, fish per hour, average length of fishing trips, total trips, per cent successful anglers, and the average size of each species taken will be made directly from the creel census records. For composition of yield, the data will be divided into seasonal periods. For each period, the estimated total catch will be equal to the product of mean daily count averages, length of census day, number of days in the period, and rate of catch in fish per hour. Data from weekdays and weekend days will be treated separately. Information will be compiled and summarized each quarter by data processing.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1621, THE FISHERY OF THOMAS HILL RESERVOIR

W.D. HANSON, State Dept. of Conserv., *Jefferson City, Missouri* 65102

Objectives: To evaluate the effects of a warm water discharge and the introduction of northern pike on the fishery of Thomas Hill Reservoir.

Procedures: Thomas Hill Reservoir, a water supply impoundment for a steam power plant, was stocked with northern pike in 1966 and annually since. The effect of the warmwater discharge and the introductions on the fishery will be evaluated in the following investigations: 1. Harvest of fish in Thomas Hill Reservoir (Job No. 1), 2. Evaluation of the introduction of northern pike (Job No. 2).

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1622, WATER QUALITY SURVEYS

M.D. MCDANIEL, State Dept. of Conserv., *Jefferson City, Missouri* 65102

Objectives: To evaluate the effects of water quality on biological productivity.

Procedures: Quality of water and its effects on biological productivity will be evaluated by measurement of the benthos in the following situations: 1. Southeast Ozarks mining water quality survey (Job No. 3) 2. Effects of scouring on benthos populations (Job No.6). 3. Water quality of the North, Salt and Cuivre River basins (Job No. 7).

SUPPORTED BY Missouri State Government

2.1623, SOUTHEAST OZARKS MINING WATER QUALITY SURVEY

M.D. MCDANIEL, State Dept. of Conserv., *Jefferson City, Missouri* 65102

Objectives: To measure the benthic fauna so that the effects of effluents from present and future mining operations can be evaluated.

Procedures: A series of 21 stations are located on streams above and below present mines. Biological data were collected at these statons during 1966, 1967 and 1968. In 1969, a visit will be made to each area and samples of benthic macroinvertebrates will be collected. Physical and chemical factors and rate of flow were measured by the Missouri State Water Pollution Board and U.S. Geological Survey personnel in conjunction with the initial survey.

Qualitative benthos samples (which are semi-quantitative) will be collected on the riffles at each station with a bottom net. The riffles and pools will be checked for mussels, crayfish and snails. Fishes were surveyed once at all stations to determine species present during 1967-68 field season.

A standard form will be used to record kind and relative number of organisms present at each station. Identification of organisms will be as follows: (a) Flatworms, annelids, and roundworms will be identified to class. (b) Flies (Diptera) will be identified to family or genus, depending on the organism. (c) Stoneflies, mayflies, caddisflies, crayfish and mussels will be identified to species when practicable. (d) Snails, crustaceans and insect group other than those named will usually be identified to genus when practicable.

Data from the stations will be tabulated and compared to determine quality and relative quantity. Results will be compared to similar studies elsewhere.. In the written final report the relationships of the benthos to the physical and chemical quality of the water (not reported by cooperating agencies) will be emphasized. The report will be arranged as an integral part of the report for the over-all project.

SUPPORTED BY Missouri State Government

2.1624, POLLUTED WATERS
W.L. REDMON, State Dept. of Conserv., *Jefferson City, Missouri* 65102

Objectives: To document the extent and severity of pollution in the state and evaluate the effects on fish and aquatic habitats.

Procedures: The results of pollution of the waters of the state will be studied as follows: 1. Pollution investigations (Job No. 1).

SUPPORTED BY Missouri State Government

2.1625, POLLUTION INVESTIGATIONS
W.L. REDMON, State Dept. of Conserv., *Jefferson City, Missouri* 65102

Objectives: To evaluate the effects of water pollution on fish and aquatic habitat.

Procedures: Fish kills will be investigated to determine the cause and duration of the kill.

In cases of pollution by toxic substances, bioassays will be conducted to determine the concentration and relative toxicity of the toxicant.

When total fish kills occur over long stretches of a stream, observations will be made to determine the time required for repopulation.

Reported water pollution will be investigated to determine the source and quantities of pollutants. These data will be supplied to state and federal agencies charged with enforcement of water pollution laws.

Experiments will be conducted on the feasibility of various methods of combating oxygen depletion fish kills.

An annual report will be prepared for comparison with previous years and to furnish data to the Federal Water Pollution Control Administration.

SUPPORTED BY Missouri State Government

2.1626, GEOCHEMICAL EFFECTS OF MINING POLLUTION ON THE STREAMS OF SOUTHEAST MISSOURI
E.A. BOLTER, Univ. of Missouri, Graduate School, *Rolla, Missouri* 65401

The proposed research aims at determining the influence of developing lead-zinc mining operations on the quality of stream waters in the 'New Lead Belt' of SE Missouri.

The investigation will include the following parts: 1) Determination of possible pollution of stream waters by heavy metals. 2) Determination of the 'self-cleaning capacity' of the streams by adsorption or precipitation. 3) Determination of the uptake of heavy metals by aquatic life species.

Samples will be collect at about 20 sampling stations. The chemical analysis of water samples, stream sediments and aquatic life species will be performed by atomic absorption spectroscopy.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1627, EFFECT OF ENVIRONMENTAL FACTORS ON DESIGN AND OPERATION OF OPEN-AIR SLUDGE DRYING BEDS
J.C. JENNETT, Univ. of Missouri, School of Engineering, *Rolla, Missouri* 65401

In order to develop rational techniques for the design of open-air sludge drying beds, it is necessary to understand the effect environment has on the process. The main approach of this investigation is to study the fundamental aspects of sludge drying and how environment is a factor.

The specific objectives of this project are to develop laboratory procedures which will allow the quantitative evaluation of the effects of environment on sludge drying; to evaluate the experimental results gained from the laboratory to determine how and to what degree environment and sludge bed design affect the rate and extent of sludge drying; and to develop a rational approach to the design and operation of these drying beds.

Laboratory investigations will be performed using model sludge drying beds in environmental chambers which allow the control of the physical environment so that each variable may be held constant or changed as desired. Laboratory and field data will be correlated to allow practical application of the results.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1628, STREAM POLLUTION IN THE NEW LEAD BELT OF SOUTHEAST MISSOURI
B.G. WIXSON, Univ. of Missouri, Environmental Health Res Ctr, *Rolla, Missouri* 65401

The proposed research plan involves field and laboratory investigations to determine the initial and cumulative effects of lead- zinc mining wastes on the water quality and aquatic biota of the presently unpolluted streams in the 'New Lead Belt' of S. E. Missouri. The unpolluted water quality and natural ecological background data have already been established since mining activity is scheduled to start in the immediate future. The unique study area makes possible a before, during, and after pollution investigation. Specific objectives are: 1. To study and evaluate the initial shock of mining pollution on the water quality and aquatic biota of affected streams. 2. To study and evaluate the cumulative effects of increasing amounts of mining pollution upon water quality and ecological systems. 3. To determine water quality and aquatic biota in control unpolluted streams in the area which will not be affected by increased population of new industry. 4. To evaluate and correlate all the investigative data and relate the findings to the unpolluted control streams and initial background survey of the streams in the study area.

Pollution effects on water quality would be evaluated by changes in pH, dissolved oxygen, turbidity, color, alkalinity and water hardness. Pollution effects on the biota would be evaluated by the response or changes in bacteria, algae, snails, crayfish, and fish.

The evaluation of all investigative data would provide information which will help conserve and protect healthy streams and biotic communities from futrue lead-zinc mining pollution.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1629, ENERGY EXCHANGE WITHIN ECOSYSTEMS
D.M. GATES, Missouri Botanical Garden, *Saint Louis, Missouri* (AT(11-1))

Objective: We wish to test a theoretical model for plant productivity by means of experiments with labelled CO2. A valid model for productivity is vital in understanding plant competition, the original goal of this project. It will also be important in understanding the interactions of herbivores and carnivores in the production cycle, and in assessing the effects of thermal pollution on plants. Scientific Background for Study: In the past few years, Gates and co-workers have worked out the energy budgets of leaves. The total energy environment of a leaf is considered and results in the temperature of a leaf being described as a function of incident radiation and several environmental variables. A model of photosynthesis has recently been worked out and is now in preparation for publication. The combining of the energy budget with the model for photosynthesis results in a model for productivity.

Proposed Procedure: We intend to thoroughly test our model by measuring plant photosynthesis, respiration and transpiration as a function of various environmental variables.

Test Objects and Agents: To do this we need an air-tight chamber in which to place the leaf or plant, an infrared gas analyzer to monitor CO2 concentration, a thin window geiger tube for monitoring labelled CO2 concentration a water vapor guage to measure transpiration rate, and a computer to assist in reducing the data.

Results: Our preliminary approach and results were presented at Proc. International Symposium 'Productivity of Photosynthetic Systems.' Moscow, U.S.S.R. September, 1969.

Since then the model has been refined. Also application of the model to relatively simple systems, such as that of corn (where total respiration in the light is apparently zero or very close to it) has yielded encouraging results.

SUPPORTED BY U.S. Atomic Energy Commission

2.1630, STUDY OF POSSIBLE EFFECTS OF STRIP COAL MINING ON THE HYDROLOGICAL REGIMEN IN EASTERN MONTANA

W.A. VANVOAST, Montana Coll. of Min. Science, State Bur. of Mines & Geology, *Butte, Montana* 59701

This project is designed to analyze the effects of strip mining of coal on the hydrologic system including changes in water quality, artesian pressure, ground water storage and surface water runoff. The hydrologic changes due to strip mining can be both detrimental and beneficial.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1631, PLUMBISM IN MIGRATORY WATERFOWL FROM FOOD CHAIN ACCUMULATION OF LEAD

M.J. BEHAN, Univ. of Montana, School of Arts, *Missoula, Montana* 59801

Lead poisoning in migratory waterfowl has been observed for nearly 100 years, and has been attributed to the ingestion of lead shotgun pellets. This project will determine the significance of lead ingestion via the food chain as a contributor to the plumbism that has been documented. The hypothesis that the lead pellets deposited in the bottom sediments of ponds are subject to chemical changes will be tested. The lead is then absorbed and accumulated by bottom-rooted aquatic plants which form the principal food source of certain migratory waterfowl in some seasons. The lead accumulated in these plants may provide an important additional source, and in some cases may be the principal source of lead ingestion. Evidence in support of this hypothesis has been shown by the presence of lead pellets in gizzards of ducks which have succumbed to plumbism.

This hypothesis will be tested by: 1. The Collection and analysis for lead content of bottom-rooted aquatic plants from areas of known high incidence of plumbism. 2. The culture bottom-rooted aquatic plants in an aquaria designed to simulate the environmental conditions of natural pond sediments but heavily impregnated with fine Pb pellets or Pb powder to determine whether lead can be absorbed by these plants from this source. 3. If lead can be detected in these artificially cultured aquatic plants, feeding experiments will be conducted to determine whether plumbism can be induced when lead is supplied solely as that in these artificially grown plants.

Results of this research may suggest significant alternative recommendations in the reclamation procedures now proposed for certain National Refuges of known regular occurrence of die off due to plumbism. In addition, information concerning the cycling of an important industrial pollutant will be provided.

SUPPORTED BY U.S. National Science Foundation

2.1632, AN INVESTIGATION OF THE WATER QUALITY AND PRODUCTIVITY OF POLSON BAY, FLATHEAD LAKE, MONTANA

A.R. GAUFIN, Univ. of Montana, School of Arts, *Missoula, Montana* 59801

This project is designed to determine the variability in productivity in various areas within Flathead Lake and to determine to what extent variations in productivity are due to local pollution rather than to natural variations in the aquatic environment. Ever increasing requirements for water make it extremely important that our water sources be kept in the best possible condition for human consumption and enjoyment.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1633, EFFECTS OF WARM-WATER DISCHARGES ON FISH IN THE MISSOURI RIVER

L. MORRIS, State Game & Parks Commission, *Lincoln, Nebraska* 68509

This job is one part of a comprehensive study to measure various chemical, physical and biological factors of the Missouri River before and after operation of two nuclear power plants. By comparing the results of these measurements, it should be possible to determine some of the environmental effects of the warm-water discharges from the plants. In each plant river water will be diverted through the plants, and used for cooling, raising its temperature about 18 degrees F. above ambient before being released back into the river. One plant will use approximately 800 cfs of water while the other plant requires about 1440 cfs of water.

Objective: To direct and participate in field work, laboratory work, data analysis and reporting of the fishery portion of the comprehensive study.

Procedures: Field work will be initiated in July of 1970 and completed in July of 1974. In the pre-operational phase field work consists of one weeklong sampling period in each of the following months: July, September, and November of 1970; and April and July of 1971.

It is anticipated that both plants will begin operation sometime between September of 1971 and June of 1972. Field work for the post- operational phase will then begin in July of 1973 and terminate in July of 1974 with the last week of each of the following months comprising the five sampling periods: July, September, and November of 1973, April and July of 1974. 1. Insure that sufficient equipment and personnel are scheduled and available at the proper times to accomplish fish and laboratory work for the fishery portion. 2. Adjacent to each nuclear plant establish the boundaries for the use of each fish collecting device. 3. Design data sheets that will insure uniform and accurate recording of all fishery data during each collecting period. 4. Supervise and participate in actual field work on the fishery portion of the comprehensive study. 5. Coordinate the laboratory work and reporting of the fishery data.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1634, EFFECTS OF WARM-WATER DISCHARGES ON FISH IN THE MISSOURI RIVER

L. MORRIS, State Game & Parks Commission, *Lincoln, Nebraska* 68509

Procedures: Field work will be initiated in April and will continue through November. Each nuclear site will be visited once weekly and fish collections will be by boat shocking, telephone shocking, seining and hoop netting at stations above and below the power plants. Although the location of these stations is determined by the location of existing stabilization structures (pile dikes and trail dikes) none of the stations will be more than five miles above or below the entrance of warm water. In order to catch adequate numbers of fish and to maintain a constant unit of sampling effort, all samplings must be confined to the pile dikes and trail dikes.

We will establish six stations for boat shocking along the trail dikes near each nuclear site. Each station will be one-half mile in length. On each side of the river, one station will be upstream and two will be downstream of the entrance of warm water. At both nuclear sites we will establish two stations (each will encompass five pile dikes) for telephone shocking. Both stations will be on the same side of the river as the nuclear site with one upstream and one downstream of the entrance of warm water. The pile dikes at each station will be shocked once weekly with the telephone shocking device during the summer season in order to collect flathead catfish. All fish will be measured, fin- clipped in a pre-determined manner and released. A nested analysis of variance will be used to detect changes in gross numbers and possibly in abundance of some species before and after operation of the power plants.

At both nuclear sites we will establish two stations (each will encompass five pile dikes) for seining and hoop netting. Both stations will be on the same side of the river as the nuclear site with one upstream and one downstream of the entrance of warm water. By seining the sandbar downstream of each pile dike we will collect forage species (mostly cyprinids). By hoop netting in the deeper water near the pile dikes we will capture several larger species including the channel catfish. Forage will be identified, counted and released. The larger species will be measured, fin-clipped, and released.

Changes in movement patterns before and after operation of the power plants will be monitored through the recapture of marked fish.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1635, INFLUENCE OF FERTILIZER PRACTICES ON WATER AND THE QUALITY OF THE ENVIRONMENT
R.A. OLSON, Univ. of Nebraska, School of Agriculture, *Lincoln, Nebraska* 68503

The project studies the fate of applied nitrogen and phosphate with different systems of fertilizer management and with particular reference to nutrient movement from the zone of root activity. Additionally; ground, surface and rain waters of Nebraska are being analyzed and chemical character of the waters related to human and livestock densities, inherent soil properties and history of fertilizer use. Nutrient accumulations from the soil surface to the underlying water table are measured by ecological regions and in relation to topography and varied soil, water, and crop management practices.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1636, EFFECTS OF ENVIRONMENTAL STRESSES ON BEEF CATTLE
H.J. WEETH, Univ. of Nevada, Agricultural Experiment Sta., *Reno, Nevada* 89507 (NEV00303)

OBJECTIVE: Investigate water and electrolyte metabolism of dehydrated animals as a means of recommending methods for alleviating natural stress conditions. Determine water and electrolyte metabolism in animals as influenced by various inorganic salts.

APPROACH: Individually penned heifers will be offered drinking water containing various concentrations of sulfate. Experimental designs will be Latin Squares. The usual meteorological, feed consumption, water consumption and body weight observations will be taken. For renal studies urine will be collected via indwelling catheters. The effects of sulfate on glomerular filtration rate and the clearance of pertinent electrolytes will be evaluated. Hemoglobin and its metabolites will be quantitated. Where expedient laboratory rats will be used for preliminary studies.

PROGRESS. A study of the effects of sulfate-contaminated water on cattle has been initiated. In preliminary work it was found that growing rats were unaffected by 7500 ppm sodium sulfate in their drinking water. They did not develop detectable methemoglobin or sulfhemoglobin. Hereford heifers would drink little or no water containing 7500 ppm sodium sulfate, but water containing 5000 ppm was consumed. This amount (5000 ppm) of sodium sulfate in the drinking water reduced feed consumption, water consumption and growth rate. The salt induced a relative diuresis. Total hemoglobin was unaffected by sulfate-water, but the heifers developed a mild methemoglobinemia and sulfhemoglobinemia. The sulfhemoglobin was detectable for at least 2 months. These effects of drinking 5000 ppm sodium sulfate water were due to the sulfate ion.

SUPPORTED BY U.S. Dept. of Agriculture

2.1637, EFFECTS OF TEMPERATURE ON THE BEHAVIOR OF ADULT ATLANTIC MACKEREL
B.L. OLLA, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Highlands, New Jersey* 07732 (AT(49-7)3045)

We have previously established normal activity patterns of adult bluefish, Pomatomus saltatrix, held in a tank under simulated diurnal changes of light, and subsequently used norms to measure temperature effects on activity rhythms. As an extension of this work we propose to study in a similar fashion the effects of temperature on activity rhythms of adult Atlantic mackerel, Scomber scombrus, and compare the results with those for bluefish. Our intention is to gain a better understanding of the responses of different species of marine fishes to thermal stress.

Beginning at an acclimation temperature of 12-13 degrees C and under a light regimen corresponding to the natural seasonal photoperiod, temperature will be raised 0.5 degrees C per day until behavioral changes occur which indicate sublethal stress. These changes might affect, a) swimming speed, b) schooling tendency, c) variability in speed and schooling, and d) rhythmic activity. The temperature at which these changes occur will be considered the upper behavioral limit. We will continue to raise the temperature to compare these significant behavioral changes with those occurring as the ultimate upper incipient lethal level is approached. These results will establish an upper behavioral limit to temperature and describe quantitatively the subtle changes which are caused by gradually increasing temperature.

Results: Observations on a small school of 8 adult Atlantic mackerel held at an acclimation temperature of 12 degrees and under a naturally changing photoperiod, have shown that they (1) have a distinct diurnal swimming speed rhythm and (2) show greater school cohesiveness at night than during the day. Part 3 of 3.

SUPPORTED BY U.S. Atomic Energy Commission

2.1638, EFFECTS OF THERMAL ADDITIONS ON MARINE ECOSYSTEMS
J.B. PEARCE, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Highlands, New Jersey* 07732 (AT(49-7)3045)

Summary of proposed work: The objective of this project is to determine the sublethal effects of thermal additions on marine ecosystems particularly communities. The lethal effects of heated discharges are reasonably well documented in scientific literature; the importance of the subtle effects of artificially heated marine waters are, however, poorly known. If future steam- and nuclear-electric plants are to be sited in an ecologically appropriate manner, subletnal effects must be well-known.

We are studying the effects of thermal additions in two dissimilar marine ecosystems; in one case we are observing the effects of a plant (Northport, Long Island) sited on the open coast of Long Island Sound. At this site there is an adequate supply of rapidly circulating, cool water. The second site is located on Barnegat Bay, New Jersey, where the circulation is restricted and ambient summer temperatures may naturally exceed 90 degrees F.

Results: Results to date: Our earlier investigations indicated that temperatures well below those which are lethal markedly affected the behavior and ecology of many marine organisms. Sublethal temperatures affected the mobility and bysal attachment of mussels and thus indirectly affected their survival under predation. We have recently observed that elevated but sublethal temperatures affect the rate of development of a marine community in Long Island Sound and probably the ultimate diversity of this community.

We are investigating the effects which elevated water temperature have on planktonic larval stages of attached and motile benthic organisms and their subsequent settling attachment, growth, survival, succession and reproduction.

Our studies in the field involve the use of artificial substrata which are placed in heated and controlled environments and periodically collected by SCUBA techniques and examined in the laboratory; the fauna associated with the substrata is fixed and preserved in a standard manner so that we can histologically assess the impact of added heat on reproductive and other tissues.

In addition, living organisms are observed in special laboratory aquaria to determine the effects of sublethal temperatures on normal patterns of behavior.

2.1639, EFFECTS OF SEWAGE SLUDGE ON FINFISH AND BENTHIC AND PLANKTONIC COMMUNITIES
J.B. PEARCE, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Highlands, New Jersey* 07732

Currently 5 million cubic yards of sewage sludge per annum are dumped at a site 4.5 nautical miles SE of Ambrose light. This practice has been continuous for the past 4 decades. Effects of sewage sludge on benthic and planktonic organisms important to the economy of sport and commercial finfishes is not known. From a grid of collecting stations bounded by longitudes 73 degrees 15' W and 74 degrees 0'W and latitudes 40 degrees 10'N and 40 degrees 32'N. We are 1) using species diversity and community stability as indices for environmental well being, 2) study-

ing movements of the sludge to determine increase in area effected, and 3) measuring viral, bacterial, and heavy metal contamination of shellfish and sediments near the center of the sewage sludge dump area.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1640, BIOLOGICAL EFFECTS OF DREDGE SPOIL AND WASTE ACID DISPOSAL PRACTICES
J.B. PEARCE, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Highlands, New Jersey* 07732

Since 1948, 2.5 million cubic yards/year of dilute acid and iron industrial wastes have been disposed of approximately 10 nautical miles SE of Ambrose Light. The peculiar yellow stain from these wastes can extend for over 20 miles in a north-south direction and up to 5 miles in width. The area provides excellent catches of pelagic sport fishes. We are studying planktonic communities to determine effects of these wastes on components of the food chain.

Collections obtained at various depths are to be compared with organisms from surrounding natural waters. Preliminary findings indicate smaller zooplankton populations exist inside the polluted water masses. We will determine experimentally lethal and sublethal effects of acid wastes. We will study a dredge spoil dump site 4.5 miles south of Ambrose Light employing techniques similar to the Sewer Sludge Study (2518-01).

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1641, EFFECTS OF THERMAL AND OTHER FORMS OF POLLUTION ON SOME ANADROMOUS FISHES
J.R. WESTMAN, Rutgers the State University, School of Agriculture, *New Brunswick, New Jersey* 08903

This research is divided into two parts: (1) the temperature tolerance and preference ranges of juveniles of four species of anadromous fishes will be determined. The species are: the striped bass, Roccus saxatilus, the American shad, Alosa sapidissima, the blueback herring, Alosa aestivalis, and the alewife, Alosa pseudoharengus (2) The dissolved oxygen requirements of the four species will also be measured at three water temperatures, and at two salinities in addition to 'fresh' water. Oxygen requirements will also be measured in the presence of various concentrations of petroleum products, of ammonia, and in the presence of both.

A temperature preference tank will be employed for determining preference ranges; and oxygen reduction will be obtained by the use of nigrogen, and by helium for comparative purposes.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1642, ENVIRONMENTAL FACTORS AFFECTING FISHERIES
J.R. WESTMAN, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00533)

OBJECTIVE: Obtain size, age, sex and percent repeat spawners of the adult shad runs in the Delaware River. Determine chief spawning and nursery areas. Determine effects of temperature on the development and survival of eggs and young. Determine effects of flow and velocity on movement of eggs. Determine oxygen and temperature requirements of the winter Flounder, Common Spearing and Northern Swellfish.

APPROACH: Sample adult shad runs each week. By observation and sampling determine spawning and nursery areas. Temperature and temperature changes and stream flow and velocity will be done experimentally at DeBruce, N.Y. Oxygen and temperature requirements for the flounder, common spearing and northern Swellfish will be conducted under controlled laboratory conditions.

PROGRESS: Striped bass, white perch and herring were studied for oxygen tolerance, avoidance of low oxygen areas, diural variation and temperature tolerance. Mortality usually appears at oxygen levels below 3 mg/l. Thermal studies included determinations of avoidance temperatures, temperatures of avoidance breakdown and death temperatures (LD 50's) of Atlantic Silversides exposed to increasing thermal gradients in our experimental gradient tank. The effects of acclimation temperature, salinity, fish size and rate of temperature change on this species thermal responses were examined. Effect of anticipated hot water discharge on fish in Barnegat Bay below reactor. Data on species composition, relative population size, and distribution of fish populations collected since 1967 will be compared to conditions after operation on stream. Relationship of nitrifying bacteria to sea water studied. Results suggest the existence of 3 different populations, namely, freshwater-adapted: Grows best in fresh water medium inhibited in 25% sea water. Tolerant: Grows in fresh water intermediate salinities and full strength seawater media. Sea Water adapted: No growth in medium containing less than approximately 5% sea water.

2.1643, THE PREDICTION AND OPTIMIZATION OF STREAM RESPONSES TO POLLUTANT WASTES
R. DRESNACK, Found. for Adv. of Grad. Study, *Newark, New Jersey* 07103

The ability of the mathematical models presently used to predict the effects of pollutant loads upon the resultant stream biochemical oxygen demand (BOD) and dissolved oxygen (DO) profiles is questionable. The problem is complicated by the fact that some of the stream parameters are difficult to measure and that the mathematical models presently used do not, in many instaces, adequately describe the physical conditions they model.

In this research, a previously developed model is presented which makes use of measured BOD and DO stream values for particular loading conditions to evaluate those stream parameters which cannot be easily measured, and then uses them, in turn, to predict the effects of future loading situations. By testing selected streams, the effectiveness of the proposed mathematical model will be evaluated.

SUPPORTED BY U.S. National Science Foundation

2.1644, TEMPERATURE REGIMEN IN TIDAL WATERS
P.K. MACEWEN, Delaware River Basin Comm., *Trenton, New Jersey*

The purpose of this study is to evaluate the short term and long term effects of heated wastes in the Delaware River Estuary. A one dimensional temperature model will be developed to predict 16 effects of heated discharges on the long term temperature of the Estuary and the effects that such heated wastes and related temperature increases have on reaeration rates, organic waste assimilative capacity and the stream ecology. Available records of local agencies (Weather Bureau, U.S. Geological Survey and State Health Departments) will provide basic input for the model.

River sampling above and below heated outfalls will be conducted to determine the size and shape of areas affected by heated wastes. These data will be used to develop mixing areas to permit controlled and regulated discharge of heated wastes into the Delaware Estuary in accordance with Commission Water Quality Regulations.

SUPPORTED BY Delaware River Basin Comm. - Washington

2.1645, EVALUATION OF WATERFOWL MORTALITY FACTORS (EXCEPT HUNTING)
S. BROWNE, State Div. of Fish & Wildlife, *Albany, New York* 12226

Objectives: To appraise the effect and extent of mortality of waterfowl by agents other than hunting.

Procedure: Factors detrimental to waterfowl, such as oil, water pollution, disease and chemicals used in pesticide work, frequently cause losses or are suspected of causing losses. Under this job indications of such losses will be investigated and, if necessary, the assistance of the Department's Water Pollution Control Unit, N.Y.S. Health Department or others will be called upon to aid in determining the cause, extent and source of the trouble. Law enforcement and Regional personnel will be requested to report cases of loss, as will sportsmen's groups through the Waterfowl Committee of the Conservation Council. Specific data on the frequency of occurrence and severity of oil-

ing will be obtained from records made at certain banding stations, hunter bag-check stations, from newspaper accounts and from other sources.

2.1646, DYNAMIC WATER QUALITY FORECASTING AND MANAGEMENT
D.J. OCONNOR, Manhattan College, School of Engineering, *Bronx, New York* 10471

The primary purpose of this research project is to evaluate the effects of treated effluents on the quality of the receiving waters, particularly with reference to the effects of nutrient compounds on both the dissolved oxygen conditions and on the dynamics of algal systems. A time-variable water quality analysis of the Great Lakes, a preliminary analysis of the dynamics of algae systems has been formulated, and a completed study of the effects of nitrification and algal photosynthesis and respiration on the dissolved oxygen in rivers has been completed. Statistical analyses of data on waste effluents has been carried out for several representative treatment plants to provide background information on waste discharge variability. It is planned to complete the nitrification study, including denitrification and other feedback effects and to develop the time variable analysis of the phytoplankton dynamics. Verification of these models will be stressed. The time variable analysis of such parameters as river flow, waste water discharge and temperature will be further pursued, particularly with reference to seasonal treatment on advanced levels.

2.1647, PHYSIOLOGICAL ADAPTATION OF TWO SPECIES OF FISHES, FUNDULUS HETEROCLITUS AND SALMO GAIRDNERI, TO ALTERED WATER QUALITY PARAMETERS
E.J. MASSARO, State University of New York, School of Medicine, *Buffalo, New York* 14214

The objectives of this project are the characterization of: (a) the effects of altered water quality parameters (temperature, pH, ionic strength, light transmission and mercury content) on the development, and viability of freshwater fishes (Fundulus heteroclitus, Salmo gairdneri, Perca flavescens, Osmerus mordax) and (b) the physiological and biochemical responses of these fishes to altered water quality parameters.

In regard to the second objective, a unique biochemical or morphological phenotype resulting from a particular set of environmental conditions would function as an 'environmental fingerprint' simultaneously characterizing the nature of the environment and the organism. It may be possible to relate a particular phenotype (morphlogical, biochemical, or both) to a particular set of environmental parameters (i.e. the conditions under which the fish has developed or is living). From acquired knowledge of the viability, growth rate, reproductive capacity, etc. (i.e. the adaptability) of fishes 'tagged' in this manner, it would be possible to make predictions concerning the future history of these species in particular environmental situations. Furthermore, the development of a characteristic 'fingerprint' would serve as a sensitive indicator of incipient water pollution and function as a built-in monitor of the existing level of pollution.

Recently, I have observed extremely high concentrations of mercury (over 2 ppm) in the skeletal muscle of the yellow perch (Perca flavescens) while the American smelt (Osmerus mordax) taken from equally contaminated waters contained only 0.2 ppm. I plan to investigate the kinetics of uptake and release of mercury (as dimethyl mercury), the mechanism of its sequestration and concentration in tissues, and its effect on the development, growth rate and viability of these species (1-11).

The biochemical phenotypes of the species to be studied will be determined by well established electrophoretic, chromatographic and enzyme kinetic techniques (12-27). Tissue and environmental concentrations of mercury will be determined by neutron activation analysis and protein binding studies will be carried out employing standard equilibrium dialysis techniques (28) in conjunction with electrophoretic and chromatographic methods and isotopic analyses.

2.1648, THE EFFECT OF TEMPERATURE AND CHEMICAL POLLUTANTS ON THE BEHAVIOR OF SEVERAL ESTURAINE ORGANISMS
E.C. RANEY, Ichthyological Associates, *Ithaca, New York* 14850

The proposed research plan is a laboratory study to determine the limit of habitable conditions in thermal effluents for estuarine fishes and macroinvertebrates. These limits will be expressed in terms of behavioral avoidances and swimming capabilities. The study is ecologically based and will be conducted under conditions commensurate with those of the Delaware River estuary.

Seven ecologically and/or commerically important species will be tested with respect to conditions which occur in thermal effluents of nuclear generating stations. Beginning with standard static bioassays, lethal concentrations of copper, zinc, and chlorine will be determined for temperatures extending from river ambient to lethal. Lethal temperatures will also be determined for these sub-lethal concentrations of copper, zinc, and chlorine. These bioassays will establish the limits for behavioral testing.

Avoidance reactions to the interactions of sub-lethal temperatures and chemical concentrations will be conducted in a factoral design for two light levels, three salinities, and two levels of dissolved oxygen. Tests of maximum sustained swimming speeds and endurance will be conducted under the same combination of conditions.

Data acquired from these tests will then be used to formulate biological (behavioral) models of the interaction of these conditions for the species under study.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1649, EFFECT OF WATER QUALITY ON FIRST-YEAR MORTALITY OF LARGEMOUTH BASS
A.W. EIPPER, State University of New York, New York Coop. Fishery Unit, *Ithaca, New York* 14850

The objective of the proposed project is to contribute to establishment of water quality standards by determining the effects of temperature, oxygen concentration and other aspects of water quality on mortality of largemouth bass during the egg and larval stages. Information on factors affecting first-year mortality of game fish species is also essential for management of populations necessary to increase the capacity of water resources to produce food and recreation. Investigations of causes of first-year mortality conducted by the New York Cooperative Fishery Unit will be continued and expanded. Additional equipment for temperature and oxygen control and monitoring will be employed to study survival of eggs and fry at various levels of temperature and dissolved oxygen. The relationships of turbidity, pH, and alkalinity to mortality will also be evaluated. Studies of the effects of water quality on predators, kinds and quantity of food available to fry, and other ecological phenomena are also planned. After preliminary observations and monitoring in nature, mortality factors will be evaluated under controlled laboratory conditions, and attempts will then be made to determine if relationships observed in the laboratory apply in earthen ponds and natural waters.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1650, BASIC RESEARCH IN THE AQUATIC ENVIRONMENT EFFECTS OF EUTROPHICATION ON PLANKTON ALGAE AND BENTHIC PLANTS COMMUNITIES
H.F. MULLIGAN, State University of New York, School of Agriculture, *Ithaca, New York* 14850

The composition of submerged and planktonic aquatic plant communities will be examined to determine the effects of different levels of enrichment over a period of 3 years. Six species of submerged aquatic plants will be established in the bottoms of twenty, one-quarter acre earthen ponds containing 200,000 gallons of water. Species selected include Potamogeton pectinatus, P. crispus, Myriophyllum exalbescans, Chara Vulgaris, Ceratophyllum demersum and Elodea canadensis. These plants have world wide distributions and commonly occur in abundance in the local aquatic plant flora.

2. WATER QUALITY

Three levels of a mixture of soluble organic and inorganic fertilizers containing nitrogen and phosphorus will be added to the water of specific ponds weekly for a period of twelve weeks during the summers of 1968 and 1969. The growth of each plant species will be observed under the different enrichment regimes. The movement of the fertilizer within the aquatic ecosystem will be followed.

By beginning with an unmodified environment and adding known quantities of enrichment material, it will be possible to isolate the effects of eutrophication on planktonic and benthic plant populations and make predictions of the effects of current cultural practices.

2.1651, THE EFFECTS OF ENVIRONMENTAL STRESS ON THE COMMUNITY STRUCTURE AND PRODUCTIVITY OF SALT MARSH EPIPHYTIC COMMUNITIES

J.J. LEE, City University of New York, Graduate School, *New York, New York* 10031 (AT(30-1)-3995)

We are studying the microbiota of marine salt marsh epiphytic communities in order to gain insight into the changes which take place, or could take place, as the result of radionuclide, thermal, organic, pesticide, and herbicide pollution. These studies, when correlated with energy-flow experiments and experimental manipulation of model microcosms, should assist in the interpretaton of the non-random distribution of foraminifera in nature and the adaptive processes in community structure which occur as a response to stress and resource changes. Identification of the structure-function relationships may give clues to the more effective use and management of this important marine habitat.

Results: Eleven papers were written or published on subprojects of this contract during the past year. The standing crop end ecological bases for species diversity of littoral foraminifera was studied. Radionuclides proved excellent tools to measure the feeding rates and growth of representative herbivores such as foraminifera and nematodes. The removal rates of Ca45 and Sr89,90 from coastal marine environments by calcareous foraminifera have been estimated. The rates of growth and reproduction of foraminifera and epiphytic algae in various experimental situations including stress were measured. Foraminifera have a complex position in the food web; they require large quantities of food for optimum rate and grow best on a varied diet. Marine bacteria have a metabolite essential to the growth of foraminifera which is unavailable in algal food. The carbon budget of the community is under study. The nutritional requirements of 11 representative epiphytic algae has been studied. All have heterotrophic capabilities but each species has a different nutritional pattern. The growth of 9 of 11 organisms was stimulated by either arginine or alanine.

SUPPORTED BY U.S. Atomic Energy Commission

2.1652, PHYSIOLOGICAL ECOLOGY OF MARINE NEMATODES FROM SALT MARSH EPIPHYTIC COMMUNITIES

J.L. LEE, City University of New York, School of Liberal Arts, *New York, New York* 10031

Funds from this grant support investigations of the biology of the most abundant, yet least known group of marine benthic invertebrates: free-living marine nematodes. The investigators concern themselves with an assessment of the ecological niche that these organisms occupy in shallow marine ecosystems, particularly in the epiphytic communities of estuarine macrophytes located near salt marshes. In addition nematode life histories, feeding habits, physiological habits, and relationships with other epiphytic organisms are being studied. These investigations are aimed at assessing energy flow through shallow water nematode populations, interspecific nematode competition under various conditions of environmental stress including crowding, physical stress, organic enrichment and other pollutants. The information gained from these investigations will add significantly to our knowledge of the ecology of coastal marine waters.

SUPPORTED BY U.S. National Science Foundation

2.1653, A STUDY OF BAY SCALLOP GROWTH DURING FALL, WINTER AND SPRING IN HEATED SEA WATER

R.C. BATSON, State Div. of Marine Resources, *Old Field, New York*

The objective is to determine the usefulness of heated discharge water from power stations and desalination plants in promoting bay scallop growth.

A sample of Bug Bay scallops collected in early fall will be divided into four equal subsamples. The scallops will be measured, and statistical analysis will be made to determine whether or not these subsamples are derived from the same population. If they are not from the same population, random divisions of a sample into four subsamples will be made until it is established that they are from the same population. One subsample will be placed in an aquarium receiving 34 gallons per hour of salt water at 50 degrees F., 60 degrees F., and 70 degrees F. Each week from early fall to spring, the scallops will be measured and returned to the aquaria. These measurements will be treated by analysis of variance and a test of critical differences to determine the effect of temperature on scallop growth.

At the same time that the study is going on in the laboratory aquaria, a field study will be made. Bug Bay scallops will be collected in early fall. Procedures described above will be used to make certain that the two subsamples of scallops come from the same population. These subsamples will be suspended from anchored floats. One will be placed near the heated salt water discharge at a power plant; the other will be placed nearby and in water not affected by the heated effluent. Each week the scallops will be measured and returned to the floats. The measurements will be treated statistically as previously described to determine the effect of power plant heated effluent upon scallop growth.

2.1654, EFFECT OF INCREASED TEMPERATURE ON CELL PROLIFERATION KINETICS OF THE GOLDFISH

H.A. JOHNSON, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

It has been shown that increased temperature shortens the lifespans of poikilotherms. The question arises as to whether this life shortening also occurs at the cellular level, i.e., whether increasing the temperature shortens the generative cycle. We have begun a study of the generative cycle of intestinal epithelium and hemopoietic tissue of the goldfish adapted to temperatures of 22 degrees, 30 degrees, 35 degrees and 38 degrees centigrade.

SUPPORTED BY U.S. Atomic Energy Commission

2.1655, TEMPERATURE AND LENGTH OF LIFE IN THE ANNUAL FISH, NOTHOBRANCHIUS GUENTHERI

A.J. ROTERMUND, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

There is evidence that alteration of environmental temperature affects the lifespan of poikilothermic organisms.

We are trying to demonstrate a life shortening in annual fish at elevated temperatures. Fish are maintained at 20 degrees, 25 degrees, and 30 degrees C. and mortality data are recorded along with causes of death when they can be determined.

SUPPORTED BY U.S. Atomic Energy Commission

2.1656, ENERGY RELATIONS IN ESTUARINE ECOSYSTEMS

R.B. WILLIAMS, U.S. Dept. of the Interior, Bureau of Commercial Fisheries, *Beaufort, North Carolina* 28516 (AT(49-7)-5)

Information on the abundance, ecology, and physiology of organisms in estuarine ecosystems is necessary to construct mathematical models simulating the energy flow through the system and suitable for predicting the systems responses to environmental stresses. Knowledge of the responses of the ecosystem to man-induced stresses, such as thermal pollution, as

well as under natural conditions, is needed for the rational management of our estuarine resources. We have chosen higher plants, plankton, benthos, and fish for laboratory and field studies. These groups are important in the overall flow of energy and cycling of nutrients; yet sufficient detailed information on these groups is not available. Our field studies are conducted in the Newport River, N.C., and adjoining estuaries, and consist of describing species composition, standing crop, and ecology. Interrelations between losses of zinc 65 from fish and their metabolic rates are being sought to obtain a method for estimating the overall metabolism of fish populations in nature. Chemical composition and decay rates of estuarine plants are analyzed as an index of nutrient contribution to the estuary through degradation processes. Laboratory research will deal with the energy content, metabolism, and growth of fish, plankton, and benthos under environmental and elevated temperatures, so that ultimately we will have the information required to model natural responses and predict responses to environmental stresses.

Results: Energy requirements of zooplankton, eelgrass invertebrates, and benthos accounted for 12, 38, and 22 percent of the net plant production in the estuaries. Routine metabolism of the pinfish population in the Newport River was 11 cal./m.2/day. The greatest part of net plant production in the estuary was dissipated as microbial respiration, and decomposer production was estimated to be larger than herbivore production. This suggested the possibility of increasing the production of commercially valuable species by manipulating food chains to direct a greater energy flow into herbivores. Part 3 of 3.

2.1657, RESPONSE OF NATURAL PHYTOPLANKTON POPULATIONS TO THERMAL SHOCK

C.M. WEISS, Univ. of North Carolina, School of Public Health, *Chapel Hill, North Carolina* 27514

The project will attempt to determine the effects of power plant operation on the primary productivity of the water used for condenser cooling. The experimental design will attempt to examine three different increases in temperature resulting from plant operating procedures, as well as effects of three lengths of discharge canal be simulation of time-temperature cooling curves. Productivity will be measured as carbon fixed per ml sample per hour using carbon 14 tagged NaHCO3. Special incubators will be used to simulate cooling rate curves as well as providing constant illumination for phytoplankton photosynthesis. Seasonal effects due to changes in phytoplankton populations will be monitored by conducting standard experiments through one full year.

SUPPORTED BY Duke Power Company - Charlotte, N.C.

2.1658, THE EFFECTS OF TEMPERATURE ENRICHMENT ON THE ECOLOGY OF STREAMS

C.M. WEISS, Univ. of North Carolina, School of Public Health, *Chapel Hill, North Carolina* 27514

Using artificial stream channels, the effect of thermal stress will be determined by examination of changes in stream metabolism. The effect of organic waste from sewage treatment plants will simultaneously be evaluated. Varying amounts of organic and heat stress will be used to establish thresholds beyond which irreversible changes in the aquatic system take place.

Artificial stream channels will be constructed of fiberglass with bottom to be covered with natural stream materials. Water from a nearby stream will be pumped into the channels. Treated sewage will be introduced to provide organic loading. One to two days flowthrough will be set depending upon specific experimental conditions with 50% of the channel flow to be heated by diversion through a high-rate hot water heater fueled by bottled gas. The heated fraction will be discharged back to the stream and will flow out over the stream surface in a plume. Heat increments of 10, 20, and 30 degrees C above ambient temperature are planned. The stream channels will be monitored to establish thermal dispersion, oxygen level, pH, cycling of plant nutrients and die-off of index organisms. The photosynthesis--respiration function of the stream, will be determined as a function of the experimental conditions. Project start is scheduled for July 1970 with construction of the artificial streams.

SUPPORTED BY North Carolina State Government - Raleigh

2.1659, A COMPARATIVE STUDY OF THE RESPONSES OF THE AQUATIC WEEDS, ZANNICHELLIA PALUSTRIS & RUPPIA MARITIMA, TO DIFFERENT TEMPERATURES AND SALINITIES

G.J. DAVIS, East Carolina University, School of Arts, *Greenville, North Carolina* 27834

Research to determine the growth responses of two useful estuarine plants (Ruppia maritima and Zanichellia palustris) to various temperature and salinity conditions is proposed. This would involve laboratory experiments with supplementary field observations. The research should be useful in predicting the effects of thermal pollution and explaining certain field observations.

2.1661, ESTUARINE ECOSYSTEMS AND HIGH TEMPERATURES

J.E. HOBBIE, Univ. of North Carolina, Graduate School, *Raleigh, North Carolina* 27607

Estuarine microcosms will be set up in 4,000 gallon pools and maintained 5 degrees C above controls. Both flowing and standing water systems will be tested with each experiment lasting 3 months. The following observations will be made throughout each experiment: phosphate, nitrate, pH, total alkalinity, particulate carbon, salinity, respiration and photosynthesis of the whole community. At the end of experiments, measurements will be made of the survival or replacement of varies species, the growth of shellfish, the biomass of algae, growth of rooted aquatics, and size and weight of fish. The object of the research is to test whether or not this approach can be used to examine the effects of nuclear power effluents in the estuary

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1662, BIOLOGY OF AQUATIC HETEROTROPHIC BACTERIA AS AFFECTED BY PHOSPHATE MINING IN AN ESTUARY

J.E. HOBBIE, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC03279)

OBJECTIVE: Study the ecology of the Pamlico River so that changes due to phosphate mining may be quantified and long-term predictions made.

APPROACH: Add differing amounts of a substrate, such as glucose-C, to a series of subsamples from natural water. After incubation, the plankton is filtered and the activity is counted. Respired CO(2) may be trapped in a basic amine and counted by liquid scintillation. The concentration of natural substrate is measured by standard chemical techniques. Laboratory bioassays of effects of various pollutants on common estuarine organisms will use variables such as temperature, salinity, phosphate, nitrate, and fluoride concentrations.

PROGRESS: The amount of nitrate nitrogen entering the Pamlico River Estuary has been measured at 30 stations over 5 months bi-weekly. The concentrations were 20-50 times higher than the usual found in estuaries. It is likely that the source is both sewage treatment plants and farm fertilization. Where the excess nitrogen mixed with high amounts of phosphate from mining operations, there was growth of phytoplankton as indicated by oxygen and pH measurements. Because there are no regulations about these levels of nitrogen and because the amount of agricul-

tural fertilization and domestic sewage will increase many fold in the next decade or so, this finding must be regarded as the first signs of pollution in the estuaries. If continued, the valuable fishing and recreation industries would be seriously damaged.

SUPPORTED BY U.S. Dept. of Agriculture

2.1663, PARASITES OF FRESH-WATER FISHES IN NORTH CAROLINA

G.C. MILLER, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC03291)

OBJECTIVE: Study the ecology and life histories of parasites in our native fresh-water fishes, especially those of economic importance and their possible relationship to man and his domesticated animals.

APPROACH: Host animals from various parts of the state will be collected and studied for the prevalence of parasitism. These host fishes will be collected by the use of setpoles, trotlines traps, angling, netting and seining. In addition, some hosts may be obtained from the North Carolina Wildlife Commission and the North Carolina Cooperative Fishery Unit. Fishes from lakes, ponds, and streams will be examined to study the effect of environmental influences on parasite burden in the host. Some smaller, non-game fishes are directly implicated in the life histories of parasites of some economically important hosts. Parasitic helminths, leeches, and copepods will be the primary organisms investigated but protozoans also may be included if they show significant parasitism.

PROGRESS: This project was just initiated in October, 1969 and therefore there is little to be reported at this time. Contacts were established with fishery biologists at Lake Norman and at Kerr Scott Lake. Samples of various species of fishes were surveyed from both lakes to determine the incidence and types of parasites in these hosts. Lake Norman especially offers some unique possibilities. The presence of the Duke Power Plant and its associated thermal 'pollution,' or rather thermal effects, offers an opportunity to study these effects on the parasitic fauna as compared with other parts of the lake and other comparable lakes. Studies have been initiated in this direction. Small samples of fishes from ponds and streams have been surveyed for parasites since it is our intention to identify and determine the importance of these parasites in fresh-water fishes in North Carolina.

2.1664, ENVIRONMENTAL EFFECTS OF COASTAL ZONE POWER GENERATION

D.A. ADAMS, Coastal Zone Resources Corp., *Wilmington, North Carolina* 28401

The contract provides for consulting services and such other assistance as Carolina Power and Light Company may request in the area of: 1. Environmental effects from coastal power generator installations. 2. Coordination and negotiation of environment related issues involving the company and Federal and State permit granting agencies. 3. Such other advice and consultations on ecological and environmental matters as Carolina Power and Light Company may desire.

SUPPORTED BY Carolina Power & Light Co. - Raleigh, N.C.

2.1665, EFFECTS OF SUGAR REFINING LAGOON EFFLUENTS ON BIOLOGICAL, PHYSICAL, AND CHEMICAL PROPERTIES OF FARGO CLAY

B.R. FUNKE, North Dakota State University, Agricultural Experiment Sta., *Fargo, North Dakota* 58103

The proposed research plan involves use of soil columns and greenhouse experiments to determine the effects of applying sugar refinery lagoon effluents to Fargo clay. The chief objectives of the investigations will be to: 1. Determine any changes in the ability of Fargo clay to allow infiltration of sugar lagoon effluents, for example, slowing due to clogging from biological or other causes. 2. Determine the effectiveness of Fargo clay in eliminating biologically degradable components of these wastes. 3. Determine effect of such wastes on selected chemical properties of Fargo clay. 4. Determine the practicality of cropping soils treated with such lagoon effluents with various types of plants.

The methods to be used would involve application of liquid wastes to soil columns of Fargo clay, both cropped and uncropped, and determining any changes in infiltration rates. Tests would be aimed at correlating any clogging with biological accumulations and physical and chemical changes in the soil. The continuing effectiveness of the soil in purifying the wastes would be determined by testing for changes in Biological Oxygen Demand and Chemical Oxygen Demand. Greenhouse pot experiments would determine effects of waste applications on growth of various plants.

2.1666, EFFECTS OF SUGAR REFINING LOGOON EFFLUENTS ON FARGO CLAY

B.R. FUNKE, North Dakota State University, Agricultural Experiment Sta., *Fargo, North Dakota* 58103 (ND-S-08-003)

OBJECTIVE: Determine the feasibility of disposing of sugar refinery effluents by spreading on Fargo clay soil.

APPROACH: Rate of infiltration of sugar refinery effluents thru soil lysimeters. Tests for possible biological origins of clogging effects. Changes of BOD after infiltration of soil. Effects on various soil chemical constituents. Investigation of types of cropping possible on soils receiving sugar refinery effluents.

PROGRESS: Infiltration rates were very slow but no significant short term clogging attributable to effluents noted. No significant difference noted between growth of alfalfa or soybeans treated with effluent or distilled water. Sudan grass did slightly better with effluent, barley did much better. Alfalfa disposed of the most water by transpiration (three successive croppings), Sudan grass slightly less (two croppings). Soybeans good but only one crop, barley poor. Comparisons of soil lysimeters treated with effluent and with distilled water showed: electrical conductivity doubled, calcium, magnesium, potassium, increased somewhat but no cause for immediate concern. Sodium increased substantially but still below level of immediate concern. Soil lysimeters treated with effluent and distilled water respectively showed: no difference in carbon:nitrogen ratio (13:1) or nitrate levels; phosphorous levels increased slightly; no change in pH with water, increase from 6.5 to 7.5 with effluent. Tests with respirometers showed rapid metabolism of organic matter in effluent when applied to soil. Metabolic activity very high, subsiding to normal soil levels in 3-4 hours.

SUPPORTED BY North Dakota State Government

2.1667, DISTRIBUTION AND ECOLOGY OF RIVER MOLLUSKS IN CENTRAL AND WESTERN NORTH DAKOTA

A.M. CVANCARA, Univ. of North Dakota, Graduate School, *Grand Forks, North Dakota* 58201

This investigation has two objectives, 1) to determine the distribution and ecology of mollusks in the rivers of central and western North Dakota, and 2) to determine the effects of water pollution in the rivers of this area as indicated by these mollusks.

This study is to be initiated and completed before natural drainages are altered by the Garrison Diversion Unit of the Missouri River Basin Project. The diversion project will effectively mix the waters of the Missouri River and Hudson Bay Drainage basins.

Ecologic factors affecting mollusk distribution, once known, can be further evaluated by ecologic impact studies after the natural drainages are altered physically or by possible water pollution. Also, present ecologic data can be related to paleoecological conditions of Pleistocene mollusks. Distribution data of the mussels may be applied to tracing former stream confluence in central and western North Dakota.

Numerous sampling stations will be established on each river system, with at least five stations on each minor tributary. At each station, all species of mollusks will be collected and their relative abundance estimated. Light penetration, turbidity, water temperature, dissolved oxygen, alkalinity, hardness, chloride content, nitrate and nitrite content, pH, and other factors will also be analyzed.

2.1668, FISH OPERCULAR RESPONSE TO ENVIRONMENTAL VARIABLES

W.A. SPOOR, Univ. of Cincinnati, Graduate School, *Cincinnati, Ohio* 45221

To define water quality favorable for aquatic organisms it is necessary to know for each environmental component the range over which its concentration or intensity may vary without adverse effects, and how any one component is related to the rest within their permissible ranges, not only directly, but also indirectly through their effects on the organisms. Relatively little of the literature on the effects of various agents on aquatic life is germane to water quality criteria at present; the major deficiencies are (1) the tests have been acute, with endpoints (usually death) too crude to be relevant to life history and productivity, (2) the effects of combinations of environmental components have received relatively little attention, (3) few species have been tested extensively, and (4) even a few have been studied at more than one or two stages of the life cycle. My research objectives are to help correct these deficiencies by using opercular movements* to detect and measure a fish's responses to changes in dissolved oxygen concentration, carbon dioxide and temperature varied alone and in combination. These three will be studied first because of their primary importance. The goldfish and the fathead minnow will be tested to begin with, the former because of its relatively slow opercular movements and because of the numerous papers on goldfish, the latter because it may be possible to relate short-term tests on opercular rate to long-term tests on life-history now being conducted at the Fish Toxicology Laboratory at Newton, Ohio. The study will include, also, an attempt to develop an improved method for measuring free carbon dioxide in water.

*The sensitivity and utility of the opercular response have been known for many years, but until recently technical problems have discouraged its use. Now that the frequency (and probably the amplitude) can be detected and recorded electrically without disturbing or damaging the fish, the technical problems seem to have been solved.

2.1670, HYDROLOGIC INFLUENCES OF STRIP MINING, BEAVER CREEK, KENTUCKY

F.F. SCHRADER, U.S. Dept. of the Interior, Geological Survey, *Columbus, Ohio* 43212

The purpose of this study is to determine the effect of strip mining for coal on the soil, water, and other natural resources. The main study area consists of two small stream basins in the headwaters of Beaver Creek tributary to Cumberland River in McCreary County, Kentucky. The study area includes one watershed in a natural state and the adjacent watershed which has been extensively strip mined.

Strip mining is a common operation in large areas of Kentucky and adjacent states. It is important to all phases of water development in the Appalachia Region to know the effects of strip-mining on the hydrologic system. This study is designed to determine both the nature and the magnitude of the effects.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.1671, THE DETERMINATION OF GROUND WATER INFILTRATION & THE EFFECTS OF INTERNAL CHEMICAL SEALING OF SANITARY SEWERS

G.E. CRONK, Montgomery Co. Bd. of Comrs., *Dayton, Ohio* 45401

We wish to determine the effect of a rising water table on defective main line sanitary sewers in combination with sewer services with probable interior house basement drains connected to sewer service. It is proposed to construct small diameter observation wells adjacent to sanitary sewers and to monitor elevation of water table with relation to invert line of sanitary sewer for long periods of time in all types weather. Test section would be about one mile long. It is proposed to expose and observe flow of some service pipes for basement houses. Construction of this phase of work is to be done by contract and observations will be done by our Consulting Engineers. Test section will be cleaned and inspected by television equipment operated by our personnel to determine condition of sewer pipes. Based on findings, we will make repairs using internal chemical sealing methods, both pressure grouting and liquid sealers. Lines will be inspected after sealing program to determine physical effects on sewer. Discharge from test section of sanitary sewers will be gauged so quantities of flow can be determined at all times, both prior to work during inclement weather and after program has been completed.

Elevation of water table and flow in sewer will be monitored during period of study. This should result in data which will show amount of benefit of process as sections of sewer are sealed. This effect should be able to be noted between sections of sewer under water table conditions and under dry conditions.

Hopefully, a byproduct of study will be data showing how sewage flow is affected in a basement home with interior foundation drains connected to cellar drains. Such information should support the County's position in further attempts to alter local building codes which permit this practice.

2.1672, THE EFFECTS OF ENVIRONMENTAL CONDITIONS ON THE SPAWNING AND SURVIVAL OF FRY OF THE WALLEYE IN LAKE ERIE

V.C. APPLEGATE, U.S. Dept. of Commerce, Natl. Marine Fisheries Service, *Sandusky, Ohio* 44870

The recent decline of walleye stocks in Lake Erie following a man- induced acceleration of the eutrophic process in the lake demands investigation of the many environmental factors which might influence the survival of young walleyes. Temperature monitoring stations were established on three known walleye spawning grounds (reefs) in the Western basin; with the object of determining the effect of temperature regimes during spawning and fry development in the success of walleye hatches. These records will also be used to determine the effects of temperature on the timing and abundance of food organisms that may be essential to the survival of walleye fry when they first begin feeding.

In addition, automatic devices for the regular and periodic sampling of plankton organisms on the reefs have been devised and incorporated into this study. Qualitative and quantitative examination of these samples will be compared with the planktonic diet of fry captured during their first weeks after hatching.

The temperature study which was started in 1963 will be continued through 1969, at which time sufficient data will have been collected to indicate the relationship, if any, between temperature variance and the success of hatch and survival of walleye fry. Temperature data from the thermograph tapes have been plotted through 1967.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1673, SUBLETHAL INFLUENCE OF POLLUTANTS ON FISH METABOLISM

J.J. OHARA, Central State University, Graduate School, *Wilberforce, Ohio* 45384

Metabolic alterations due to the presence of copper ions are being investigated for a range of concentrations from lethal to a level of no effect.

Fish are tested in a sealed controlled environment chamber using recycled water. Response to the toxicant is determined using oxygen uptake as the metabolic indicator. This is monitered through an oxygen meter built into the system.

Oxygen uptake is probably the most sensitive measure of metabolic alterations and these kits provide data on toxicity, recovery periods and levels of no effect for bluegill sunfish.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1674, COMPARISON OF ENERGY FLOW PARAMETERS OF MIDGE POPULATIONS IN BIOLOGICAL OXIDATION PONDS

J.L. WILHM, Okla. St. Univ., Graduate School, *Stillwater, Oklahoma* 74075

The proposed research involves a study of the effects of pollution on the flow of energy through populations of midge larvae (bloodworms). Midge larvae are extremely abundant in enriched areas and have a pronounced effect on the ecosystem. The experimental area is a series of 10 biological oxidation ponds which are the terminal treatment of effluent from an oil refinery in Ponca City, Oklahoma. Thus, it will be possible to compare bioenergetics of the populations under varying degrees of pollution.

The procedure includes the following: 1) Measure energy content in the diet items, in the standing crop of the different instar stages of bloodworms, and in the major predators of the bloodworms in four of the series of 10 ponds. 2) Measure aerobic respiration rates in the different instar stages of bloodworms inhabiting the different ponds. 3) With the data accumulated in the study and in a concomitant study of bloodworm populations, construct energy flow models for the bloodworm populations living under different levels of environmental stress. 4) Discern variations in water quality as reflected in energy flow and in ecological ratios in bloodworm populations.

2.1675, COMPUTER SIMULATION OF EUTKOPHICATION

D.A. BELLA, Oregon State University, School of Engineering, *Corvallis, Oregon* 97331 (C-1819)

The Project seeks to develop digital computer simulation methods of eutrophication in lakes, rivers and estuaries. The methods will include algal growth, nutrient regeneration, predator removal, mixing and other factors which influence algal population dynamics.

The study will begin with an examination of different growth models. Satisfactory growth models will then be combined into food chain models. Models will then be expanded to include the effects of mixing and water movement. Comparisons to existing experimental data will be made throughout the study. Through these models the interrelationships between the numerous factors influencing algal growth will be studied. The sensitivity of assumptions made will be tested. Methods of simulating alternate abatement measures will be developed and studied.

2.1676, EFFECTS OF CHEMICALLY AND BIOLOGICALLY MODIFIED PULPING EFFLUENTS ON THE PRODUCTION OF FISH

R.O. BLOSSER, Oregon State University, School of Engineering, *Corvallis, Oregon* 97331

To determine whether various chemical and biological modifications of pulp mill effluent are effective in reducing their toxicity to finned fish.

Progress to Date: The effect of biological modifications of kraft effluents on short term acute toxicity has been initiated. This work will be expanded to include detailed characterization of other effluents and assessment of biological and chemical modification on short term acute toxicity and productivity of finned fish.

SUPPORTED BY Oregon State Government

2.1677, CONTROLLING THERMAL POLLUTION IN SMALL STREAMS

G.W. BROWN, Oregon State University, School of Forestry, *Corvallis, Oregon* 97331

(1) Relate density and composition of streamside vegetation to the energy budget of forest streams, (2) using the information from the first objective, relate vegetation density and species to stream temperature changes and (3) prepare a vegetative model for use by foresters to aid them in manipulating stream-side vegetation when preparing plans for logging near streams.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.1678, PULP MILL EFFLUENT DISPOSAL

F.J. BURGESS, Oregon State University, School of Engineering, *Corvallis, Oregon* 97331

Research will be conducted on predicting the effects of kraft mill waste disposal in the ocean on the marine environment. A remote sensing system and aerial photography will be utilized to estimate waste concentrations, water currents, diffusion coefficients, and vertical waste concentration profiles in an ocean outfall plume. Aerial photography will be taken with a multispectral camera system of the waste field. Boat sampling will be conducted at the same time to provide 'ground truth' data. Data will be compiled and analyzed by a system of computer analysis which was developed for this purpose in 1968-69.

The investigation will include several kraft mill outfalls along the Oregon coast. Results of bioassays and chemical analyses will be related to photographic imagery. Zones of water quality influence about existing outfalls and proposed outfalls will be estimated, and diffusion coefficients will be estimated.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1679, LITERATURE RESEARCH ON WATER QUALITY REQUIREMENTS AND TOXICOLOGY OF FISHES

P. DOUDOROFF, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

Annotated bibliographies and copies of all obtainable materials (literature) on recent advances in fish toxicology relating to water pollution in the Soviet Union (USSR), the toxicity to freshwater and marine fishes of simple and complex cyanides, ammonia and ammonium compounds, sulfides, and carbon dioxide (world literature), and the dissolved oxygen requirements of marine fishes (world literature) are to be assembled and some of the collected materials studied and abstracted. This is to be the first phase of a proposed, continuing literature research project, being preliminary to the planned preparation of detailed, critical reviews of the literature on the above subjects, which should be useful in connection with future development or refinement of water quality criteria for the protection of fisheries and in the planning of further experimental research.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1680, HYDROLOGY OF SMALL MOUNTAIN STREAMS

J.T. KRYGIER, Oregon State University, School of Forestry, *Corvallis, Oregon* 97331 (ORE-F-00850)

OBJECTIVE: Determine the significance of logging and road building on streamflow.

APPROACH: Five watersheds under 130 acres each have been gauged since 1962 and are being calibrated to a U.S. Geological Survey Control Watershed nearby. Storm flows and other characteristics are separated from the hydrographs and compared to the control data by regression techniques for periods before and after road building and logging.

PROGRESS: Effect of clearcut logging on several watersheds in the Coast Range of Oregon has been evaluated for effects on peak discharge, volume, time-to-peak, and other flow parameters. Covariance techniques were applied to control and treated watersheds before and after logging to determine if significant

changes occurred. Peak discharge was increased significantly on two clearcut watersheds. Larger increases were noted in the fall than during winter. Quick flow, delayed flow, and total flow were increased from the larger cutover. Time-to-peak was not altered. Current analysis is emphasizing roads and cutover units on Deer Creek watershed (25% clearcut).

SUPPORTED BY Oregon State Government

2.1681, IMMEDIATE EFFECTS OF LOGGING ON THE FRESHWATER ENVIRONMENT OF SALMONIDS
R.L. LANTZ, Oregon State University, State Game Commission, *Corvallis, Oregon* 97331

Objectives: 1. To measure environmental changes in salmon spawning and rearing areas during and immediately after logging. 2. To determine the influence of any environmental changes on fish populations.

Justification: This project expands current research efforts to investigate, on a long-term intensive basis, the effects of logging on salmonids in three Alsea River tributaries. Information from a larger number of streams, studied on a less intensive basis, will provide a broader sample of the effects of timber harvesting activities, eliminate the single-area content, and make the entire study more representative of conditions along the Oregon coast.

Procedures: Trained crews measure a variety of parameters on predetermined sampling schedules one year before and one year after logging occurs. Parameters monitored include dissolved oxygen content of surface and intragravel waters, water temperature, streamflow levels, gravel compositon, pH, and fish population estimates. Specific sampling units have been established on twelve coastal streams. To date, prelogging information has been collected on all of the streams. Post- logging data has been collected on four streams.

SUPPORTED BY Oregon State Government

2.1682, MARINE FISHERIES - ESTUARINE ALGAL COMMUNITIES
C.D. MCINTIRE, Oregon State University, School of Science, *Corvallis, Oregon* 97331

The research and training is concerned with the physiological ecology of benthic algal communities and the interrelationship with animals of commercial importance.

Field data on the structure, i.e.species composition and relative abundance, and on the production of benthic diatom communities has been obtained for over a 12 month period from the Yaquina estuary. Much of this data has been analyzed relative to light intensity, salinity and desiccation resulting from tidal cycles. A manuscript will soon be submitted for publication.

The model laboratory ecosystem, located at the OSU Marine Science Center, has provided information on the structure and productivity of benthic algal communities. Experimental data concerning light intensity and desiccation has provided baseline information used for analysis of changes in community structure and productivity under the effects of reduced salinity or heated water. The results of these experiments were, briefly, productivity increased when freshwater or heated seawater were introduced into a marine environment. But, the species diversity (number and relative abundance) decreased, which often leads to a very unstable community. Generally, instability will damage the food chain structure and may place great stress on the feeding habits of commercially important animals. Barry Wulff, the trainee, has performed the laboratory experiments and his Ph.D. thesis will be completed in August, 1970.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1683, PHYSICAL FACTORS AFFECTING OREGON COASTAL POLLUTION
V.T. NEAL, Oregon State University, Graduate School, *Corvallis, Oregon* 97331

The central aim of this research is to provide information on and understanding of the physical factors that will control the pollution of certain Oregon coastal areas. These physical factors are primarily circulation and water density distribution (therefore salinity and temperature) in the nearshore region and the tidal regime in and near the mouths of estuaries. Dissolved oxygen will also be an important factor in determining 'safe' pollution levels. Therefore these factors will be measured and their variability determined at selected places.

The time variability of these factors will be determined as a function of seasonal and meteorological conditions.

All data forthcoming from this project will be made available immediately to the Pacific Northwest Water Laboratory at Corvallis, Oregon. Since the knowledge to be gained by this project is needed by that agency, the planning and operation of this program will be arranged in close cooperation with the personnel of that agency.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1684, RELATIONSHIP OF AQUATIC FLORA TO WATER QUALITY AND POLLUTION
H.K. PHINNEY, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00275)

OBJECTIVE: Establish a continuing research program concerning the relation of aquatic flora to the quality of water supplies and water pollution. Determine by biological studies of aquatic habitats, the relation between biotic and edaphic factors that are responsible for changes in the quality of water resources. Coordinate and extend studies presently conducted in the general area of aquatic botany.

APPROACH: Study of the structure of natural aquatic communities existing under varying degrees of pollution. Field and laboratory studies of the metabolic status of these communities. Development of simplified communities under controlled laboratory condition in artificial ecosystems. By use of information obtained in approaches 1-3 the structure of communities of aquatic plants and their metabolic status can be related to variations in individual ecological factors and to human activity.

PROGRESS: Projects brought to completion: (a) The culture of planktonic algae from Yaquina Estuary and the suitability as food for larval shellfish. Two manuscripts are in preparation. (b) The effects of kraft process mill wastes on benthic algae in laboratory stream. Manuscript in preparation. (c) Ecology of benthic microalgae of estuarine intertidal sediments. Manuscript in preparation. Projects to be completed by July 1, 1970: (a) Distribution of benthic microalgae in Yaquina Estuary in relation to season, temperature and salinity. New projects undertaken: (a) The effects of kraft process mill wastes on benthic algae in controlled flow streams. (b) The control of distribution of intertidal algae by biological interactions.

SUPPORTED BY Oregon State Government

2.1685, EFFECTS OF PULP MILL EFFLUENTS ON THE GROWTH AND PRODUCTION OF FISH
C.E. WARREN, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331

This is Phase II of an investigation directed toward determining the highest concentrations of untreated and biologically stabilized kraft mill effluents which, either by direct effects on salmon and trout or by indirect effects through their food chains, will not reduce their production in receiving waters. Research under Phase I of this investigation has established the concentrations of such effluents which just begin to affect the growth of salmon in aquaria and the concentrations which under different conditions in laboratory stream communities may begin to be deleterious to production of these fish. Phase II of this investigation is to extend the research to conditions more nearly resembling those in receiving waters. For this purpose, large experimental stream channels have been constructed at the site of a kraft mill. Here in long-term experiments, we intend to establish those concentrations of untreated and biologically stabilized kraft mill effluents, which either by direct effects on salmon and trout or by effects on their food chains, can be expected to reduce the production of these fish in nature. Phase II research initiated July 1, 1969 for a period of three years.

2. WATER QUALITY

2.1686, ECOLOGICAL STUDIES OF AN EXPERIMENTAL STREAM

C.E. WARREN, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

Changes in streams, whether due to natural causes or the activities of man, bring about changes in the pathways by which energy from its various sources reaches organisms of interest to man. For about twenty years, biologists have been studying the pathways of energy transfer and efficiencies with which energy is transferred through aquatic communities. Because of the complexity of most biological communities, these studies have not progressed far. Nevertheless, certain of the approaches and methods that have been used in such studies have promising application in the solution of water pollution problems. The general objectives for our studies are (1) to identify key relationships between important organisms and their environments and determine how these are affected by pollutional changes, and (2) to find or develop and test practical approaches, parameters, and methods for utilizing these relationships in the solution of water poliution problems.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1687, EFFECTS OF KRAFT PULP MILL EFFLUENTS ON THE GROWTH AND PRODUCTION OF FISH

C.E. WARREN, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00781)

OBJECTIVE: Determine the influence of biologically treated and biologically stabilized pulp mill effluents on the food habits, food comsumption, growth and production of salmonids and on biological communities in laboratory streams, experimental streams, channels and in nature.

APPROACH: Laboratory studies on the influence of these effluents on the growth of fish provided known food rations will make it possible to determine to what extent changes in growth and production of fish in laboratory streams, in controlled experimental streams, and in rivers are due to direct effects of the effluents on the fish themselves. Studies on the influence of effluents on the food consumption, growth, and production of fish and on the organisms comprising the food chain of these fish in simplified communities in laboratory streams will provide knowledge of not only the direct but the indirect effects these effluents are likely to have on fish production. Studies on a much larger scale in controlled experimental streams will provide knowledge of the effects of effluents on fish production in biological systems that are more nearly natural. Finally, studies on rivers receiving kraft mill effluents will provide necessary information for the design and interpretation of the other studies as well as information that will be necessary to define and solve actual problems concerning the influence of effluents on fish production.

PROGRESS: Kraft mill effluents, both untreated and biologically stabilized, can have a direct effect on the growth of juvenile chinook salmon fed in aquaria at final BOD levels between 0.5 and 1.0 mg/l and above. There are, however, differences being either more or less toxic than this. Both untreated and biologically stabilized kraft mill effluents can reduce the production of juvenile chinook salmon in laboratory stream communities when introduced at a rate of 1.5 percent by volume, even though this results in BOD levels of 0.3 mg/l for the treated effluent as compared to 3.0 mg/l for the untreated effluent. Some of the toxic substances present in the effluents must not be reduced by biological stabilization in proportion to BOD.

SUPPORTED BY Oregon State Government

2.1688, EFFECTS OF LOGGING ON SALMON POPULATIONS IN COASTAL STREAMS

J.D. HALL, State Fish Commission, *Portland, Oregon* 97201

This segment of research is part of the Alsea Watershed Study, designed to determine the effects of Douglas-fir logging practices on the physical and biotic resources in small coastal watersheds. The objective of the research covered in this project is to determine the effects of two patterns of timber harvest (complete clear-cut versus patch-cut) on the abundance of coho salmon in coastal streams. The work funded by this project is concerned primarily with analysis, interpretation, and publication of results of the study.

In fiscal year 1971 there exists an unusual opportunity to study factors affecting downstream migration of newly emerged fry and the effects of logging on carrying capacity of headwater streams. There was a very small adult run into the study streams in the past winter. Therefore, it will be possible to carefully monitor the distribution of these fish and contrast their migratory patterns in logged and unlogged streams.

2.1689, AN EXPANDED PROGRAM OF RESEARCH IN FRESHWATER ECOLOGY

UNKNOWN, Acad. of Nat. Sci. of Phila., *Philadelphia, Pennsylvania* 19103

An expanded research program is being undertaken, focused on the structure of natural aquatic communities and the flow of energy through them. This should lead to better means of determining the effects of specific pollutants and of learning how different aquatic communities can be managed so as to resist or neutralize pollutants. Moreover, it appears that qualitative comparisons may be made between aquatic communities and other types of collectivity, even human; there is thus the possibility that useful analogies regarding energy flow and psychobiological environmental quality, applicable to the urban environment, may be drawn from the results of these studies.

SUPPORTED BY Rockefeller Foundation - New York, N.Y.

2.1690, CYTOPATHOLOGY IN FISH EXPOSED TO STREAM POLLUTANTS

A. ANTHONY, Penn. State University, School of Science, *University Park, Pennsylvania* 16802

The major focus of this project is on histochemical and histophysiological consequences of acid exposure on gills, blood, liver and other organs of representative species of native Pennsylvania fish. One of the important practical objectives is the development and evaluation of short term methods of predicting what constitutes a safe level of a specified stream pollutant using quantitative histochemical bioassay procedures. Laboratory and field experiments will be conducted using subacute (1 mo) and acute (4-7 d) exposures. Comparisons will be made on hatchery-bred and native brook trout. Laboratory tests will involve the use of a gravity-flow diluter system with automated pH regulation and field tests will entail maintaining fish in enclosure pens placed in streams rated as good, marginal and poor with respect to mine acid pollution.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1691, FISH AND FOOD ORGANISMS IN MINE ACID WATERS OF PENNSYLVANIA

R.L. BUTLER, Penn. State University, State Coop. Fishery Unit, *University Park, Pennsylvania* 16802

The objectives are: (1) Determine the species of fish and their abundance in waters exposed to different concentrations of mine acids throughout Pennsylvania and relate their distribution to total alkalinity, total acidity, pH, sulfate and specific conductance. (2) Quantify one or more behavioral responses to cover in at least two species of fish which can be used for measures of chronic toxicity within the assumed chronic pH ranges of 4.5 to 6.0. (3) Carry out similar behavioral assays with treated mine water from acid treatment plant developed under FWPCA grant WPRD-34-01-68 at Hollywood, Pennsylvania.

A 2-man crew will continue to obtain fish samples from selected streams that are exposed to mine acid conditions. Measurements will include species, number and sizes of fish, pH, total alkalinity, total acidity, total sulphate and conductivity at each site of collection. A summary analysis will be made of all collections for fish species and abundance throughout the state.

Chronic toxicity bioassays of fish species will be made on 2-hour tests of response to cover within a 40-foot stream aquarium. Statistical comparisons will be made for each species under clean, mine acid and treated water conditions.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.1692, ECOLOGICAL PARAMETERS OF THE DEVELOPMENT AND FEEDING HABITS OF SIMULIUM SPP. (BLACK FLIES)

G. FIELD, Univ. of Rhode Island, Agricultural Experiment Sta., *Kingston, Rhode Island* 02881 (RI00625)

OBJECTIVE: Determine the natural food of black fly larvae. Determine the effect of eutrophication of streams on the development of black fly larvae. Determine the faunistic relationships of black fly larvae. Establish a laboratory culture of simuliids.

APPROACH: Field studies: Locate streams in which simuliids occur. Determine parameters of the ecological system. Determine water quality. Laboratory studies: Determine adequate larval diet. Determine effects of eutrophication by nitrates and phosphates on larval dietary.

PROGRESS: A number of streams in Washington County has been surveyed and the greatest concentrations of simuliid larvae have been found in streams receiving mild organic pollution. Larvae of Simulium vittatum zett. have been found to be abundant in a stream receiving discharge from a private fish hatchery. Large populations of chironomid larvae, isopods, and amphipods are also found in the same stream. Also, there is a large biomass of aquatic weeds which may be due to the increased productivity of the stream. Large numbers of black fly larvae have also been found in waters flowing from eutrophic ponds. Larvae of Simulium decorum Walk. have been found in large numbers in streams of this nature. Preparations are under way to determine chemical and physical parameters of streams supporting heavy populations of larvae. Tests for phosphate, nitrates, total solids have been worked out.

SUPPORTED BY U.S. Dept. of Agriculture

2.1693, CHEMICAL RESPONSES BY MARINE ORGANISMS TO STRESS

H.P. JEFFRIES, Univ. of Rhode Island, Graduate School, *Kingston, Rhode Island* 02881

The ocean is physically stable compared with land and freshwater environments, and the medium has intimate association with the life it bathes. Consequently marine organisms have developed less complex regulatory systems than their terrestrial and aquatic counterparts. But when the ocean does change -- by natural processes or as the result of pollution -- it follows that the biotic community will also change, along with the ecosystem's ability to process waste materials. Homeostatic control at the community level is, therefore, an essential element in understanding the sea's populations, especially in coastal waters where environmental oscillations are large.

The major goal of this investigation is to identify and measure quantitatively the ways marine communities respond to ecological stress. The internal responses are measured in terms of homeostasis; the external stresses result from temperature, salinity, competition, food and pollution.

The first phase of this investigation showed that the balances of free amino acids, fatty acids and blood constituents are sensitive indicators of environmental conditions. Relationships observed in nature between external stress and internal composition are now being analyzed in the laboratory. In addition, the genetic determinants of chemical specificity will be separated from environmental influences in copepods, mollusks and fishes.

When we know the minimum stress intensities and corresponding maximum internal tolerances within which normal community composition and function are maintained, we should be able to predict the fate of populations living under various conditions of water quality.

2.1694, CHEMICAL RESPONSES BY MARINE ORGANISMS TO STRESS

H.P. JEFFRIES, Univ. of Rhode Island, School of Oceanography, *Kingston, Rhode Island* 02881

The ocean is physically stable compared with land and freshwater environments, and the medium has intimate association with the life it bathes. Consequently marine organisms have developed less complex regulatory systems than their terrestrial and aquatic counterparts. But when the ocean does change -- by natural processes or as the result of pollution -- it follows that the biotic community will also change, along with the ecosystem's ability to process waste materials. Homeostatic control at the community level is, therefore, an essential element in understanding the sea's populations, especially in coastal waters where environmental oscillations are large.

The major goal of this investigation is to identify and measure quantitatively the ways marine communities respond to ecological stress. The internal responses are measured in terms of homeostasis; the external stressors are temperature, salinity, competition, food and pollution.

The first phase of this investigation showed that the patterns of free amino acids, fatty acids and blood constituents are sensitive indicators of environmental conditions. Relationships observed in nature are now being analyzed in the laboratory. Hard clams from polluted water have persistent patterns of abnormality. A shrimp is being used as another laboratory test organism.

When we know the natural stress intensities and internal tolerances, we should be able to predict the fate of populations living under various conditions of water quality.

2.1695, DEPENDENCE OF FISH ON TIDAL MARSHES

S. NIXON, Univ. of Rhode Island, School of Oceanography, *Kingston, Rhode Island* 02881

As part of a continuing effort to develop a mathematical simulation model of the physical oceanography, ecology, and economics of Narragansett Bay, a preliminary computer model will be extended to include more realistic parameters of tidal flushing, river and sewage inflows, and more complex biological interactions. An attempt will also be made to further develop the interface between ecological and economic dimensions of the model so that it may become a useful tool for long- range management of the bay.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1696, CHARACTERISTICS OF ORGANIC SUBSTANCES IN TIDAL MARSHES AND BENTHIC ENVIRONMENTS

J. QUINN, Univ. of Rhode Island, School of Oceanography, *Kingston, Rhode Island* 02881

1. To measure the contribution of organic substances from tidal marshes to the organic matter found in estuarine waters and sediments.

2. To study the equilibrium between dissolved, particulate and sedimentary organic matter.

3.To establish the trophic relationships between natural organic matter and the estuarine community and the effect of pollutants on these relationships.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1697, HEALTH EFFECTS OF TOXIC CHEMICALS WITHIN THE WATER ENVIRONMENT

A.S. ZYGMUNTOWICZ, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Narragansett, Rhode Island* 02882

Real or potential threats are posed by chemical contaminants in our drinking water supplies and certain of these are recognized to have cumulative, long-term deleterious effects, including chronic and incapacitating illnesses. The variety and complexity of such chemical contaminants are rapidly increasing. During the time that the precise health effects of such materials are being investigated, while we attempt to develop or improve our capabili-

ties to qualitate and quantitate their presence, while methodology for their removal or preclusion is under design. humans are serving as filters and accumulators for many of these substances. The potential for widespread illness is in all likelihood compounded by synergistic effects as well as reinforcement by pollutants introduced from other environmental media.

Objectives: To investigate those mechanisms of concentration of toxic chemicals within the water environment, including the biochemical and physiological implications for human health that will permit the establishment of chemical standards.

Accomplishments through FY-1970: Prior to the CWSS, the cumulative effects of cadmium, chromium, copper, and zinc on whole body glycogen, glutamic-oxalacetic transaminase, malic dehydrogenase and shell growth were measured over a 20-week period. While investigation into the biochemical mechanisms of heavy metal accumulation was carried out in shellfish, the result of this type of study may be significant in the analysis of physiological effects of toxic metals in mammalin systems exposed to environmental pollutants, their competition and binding to active sites and possible mechanisms of detoxification in the system. Data to date indicates that animal (oysters) exposed to continuous levels of cadmium (0.1 and 0.2ppm) show lower glycogen levels on the higher cadmium level than do controls. Transaminase levels appear to be slightly elevated in low cadium, while malic dehydrogenase in both cadmium concentration is significantly elevated over control values. Malic dehydrogenase activity is markedly depressed on both high and low copper levels (0.25 and 0.05 ppm). High zinc (0.2 ppm) also appears to depress transaminase activity after 9-10 weeks. Carbonic anhydrase, a zinc dependent enzyme found in many animal tissues, is active in hydrating CO2 to carbonic acid.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.1698, EFFECTS OF ELEVATED TEMPERATURE ON SPAWNING AND DEVELOPMENT OF FISHES

C.R. ARNOLD, U.S. Dept. of the Interior, Bureau of Sport Fish. & Wlfe., *Narragansett, Rhode Island* 02882 (AT(49-7)3045)

Fish spawning appears to be triggered by critical levels of temperature and photoperiod. For inshore marine species we plan to experiment with varying temperature and photoperiod to determine the precise rate of spawning advancement to be expected with exposure to artificially heated waters. In a graded series of temperatures we will determine the relation between development, survival and production of deformities in embryos of winter flounder, scup, tautog, and striped bass. A series of thermal shock experiments is planned for embryos held in salinities from 0.5 - 36 ppt. Experimental lots of larvae, acclimated at normal temperatures, will be exposed to a thermal shock. The behavior and subsequent development of larvae will be observed during a sufficiently long post-shock period to determine latent effects. The reproduction, survival and growth of minute forage organisms important to the diet of larval finfish will also be studied under different ambient temperatures.

Results: In early phases of the study relating thermal variations to development of marine fish eggs and larvae, eggs of scup, winter flounder and cod, subjected to temperature increases up to 8C for 1/2, 1-1/2, and 2 hour periods usually had a significant mortality prior to hatching. Part 2 of 3.

2.1700, PHARMACOLOGY OF METAL POISONING IN ESTUARINE FISHES

R. EISLER, U.S. Dept. of the Interior, Federal Water Quality Admin., *West Kingston, Rhode Island* 02892

Pilot bioassays were conducted under laboratory conditions with mummichogs, Fundulus heteroclitus, against various metals abundant in solid wastes dumped off shore. Analyses by atomic absorption, and other methods, of mummichogs that died during exposure to high concentrations demonstrate measurable changes in elementary chemical composition. Tissues from fishes surviving sublethal exposures were also significantly different from controls in levels of one or more of the 25 metals measured. The significance of these changes in terms of enviromental stress and metabolic pathways is being studied.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1701, COMPARATIVE TOXICITIES OF METALS TO ESTUARINE FISHES

R. EISLER, U.S. Dept. of the Interior, Federal Water Quality Admin., *West Kingston, Rhode Island* 02892

Disposal of solid wastes at sea is being practiced by an increasing number of municipalities. Preliminary analysis of incompletely-ashed incinerator wastes by atomic adsorption indicates that aluminum, iron, calcium, zinc, sodium, potassium, and lead--in that order--are most abundant. Short-term bioassays with inorganic salts of these and other metals to the mummichog, Fundulus heteroclitus, are being conducted under controlled environmental conditions. Relationships between mortality, physical-chemical environment, and concentration of test metal in solution is being investigated.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1702, EFFECT OF NITRILOTRIACETIC ACID (NTA) UPON THE TOXICITY OF METALS TO SELECTED SPECIES OF ESTUARINE PHYTOPLANKTON

S.J. ERICKSON, U.S. Dept. of the Interior, Federal Water Quality Admin., *West Kingston, Rhode Island* 02892

Laboratory studies will be conducted to determine the relationship of nitrilotriacetic acid (NTA), a metal chelator, to the toxicity of metals to selected species of estuarine phytoplankton. The metals employed in this study will be those which are known metabolic toxins and are of importance from the standpoint of estuarine pollution.

The toxicity of the various metals to six species of phytoplankton will be determined in the presence of several concentrations of NTA. In addition to growth rate, C14 labeled carbon dioxide will also be employed as a parameter for determining levels of metal toxicity.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1703, EFFECTS OF PETROLEUM AND PETROLEUM WASTES UPON IMPORTANT SPECIES OF ESTUARINE PHYTOPLANKTON AND ZOOPLANKTON

J.H. GENTILE, U.S. Dept. of the Interior, Federal Water Quality Admin., *West Kingston, Rhode Island* 02892

The effects of petroleum and petroleum wastes upon important species of estuarine phytoplankton and zooplankton will be assessed. Assays on zooplankton will employ acute toxicity to various stages in the organisms' life history as the principal parameters. Assays on phytoplankton will involve the effects of pollutants on growth, photosynthesis, and respiration as well as mechanical effects such as cell lysis. Comparative toxicity of different types of petroleum products will be investigated.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1704, HISTOPATHOLOGIC EFFECTS OF POLLUTANTS ON CELLS AND TISSUES OF MARINE FISHES

P.P. YEVICH, U.S. Dept. of the Interior, Federal Water Quality Admin., *West Kingston, Rhode Island* 02892

Histopathologic studies will be conducted on various species of marine fishes after exposure to pollutants. Studies presently are being conducted on mummichogs being exposed to Cd and Pd.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1705, HISTOPATHOLOGIC EFFECTS OF POLLUTANTS ON CELLS AND TISSUES OF MARINE INVERTEBRATES

P.P. YEVICH, U.S. Dept. of the Interior, Federal Water Quality Admin., *West Kingston, Rhode Island* 02892

Histopathologic studies will be conducted on various species of marine invertebrates: quahogs, soft shell clams, oysters, lobsters, shrimp, blue crab, etc. after exposure to various pollutants. Studies are presently being conducted in cooperation with the Northeast Marine Health Sciences Laboratory on quahogs (Mercenaria mercenaria) which have been exposed to 0.05 and 0.025 ppm of Cu, 0.2 ppm of Zn, 0.2 and 0.1 ppm of Cd and 0.05 and 0.1 ppm of Cr.

2.1706, THERMAL EFFECTS IN FLOWING STREAMS

R.S. HARVEY, U.S. Atomic Energy Commission, Savannah River Plant & Labs., *Aiken, South Carolina* 29801 (AT(07-2)-1)

The objective is to use laboratory streams to learn the effects of heated effluents, such as those produced by power generating plants, on the biota in natural streams receiving the thermal waters.

Organisms in reactor effluent streams are exposed to nonlethal changes in temperature, and we want to know the effects of slightly elevated temperature on the biota.

Results to date: Pilot studies are in progress to determine the optimum flow and the best design for the experimental streams. The Thermal Effects Laboratory will be erected on Upper Three Runs Creek, which will serve as a source of substrate, water and organisms for the experimental streams. Factors such as current velocity, temperature, gas and nutrient concentrations, light intensity, and turbidity will be subject to varying degrees of control.

SUPPORTED BY U.S. Atomic Energy Commission

2.1707, THERMAL EFFECTS IN RESERVOIRS (LAKES)

J.S. MARSHALL, U.S. Atomic Energy Commission, Savannah River Plant & Labs., *Aiken, South Carolina* 29801 (AT(07-2)-1)

The ecological effects of hypernormal temperatures in lakes due to condenser discharges from electric power plants are important considerations in reactor siting.

The initial emphasis in this program is on the short-term effects of hypernormal water temperatures on the rates of primary plankton production and plankton community respiration. Work will then move to the long-term effects of hypernormal temperatures on species diversity and population dynamics, with emphasis on zooplankton.

Studies will be made of short-and-long-term effects of hypernormal temperatures on nonplanktonic organisms in a cooling reservoir, including periphyton, macrophytes, macro- and microinvertebrates, and possibly certain vertebrates.

Field observations will be supplemented with laboratory experiments. Experiments are designed to determine the interaction of temperature with other key variables such as light intensity and nutrient concentration.

Results to date: Measurements of the effects of elevated temperatures in the cooling reservoir on photosynthetic carbon fixation by phytoplankton showed that the results obtained during the summer of 1969 confirm those reported earlier for the winter months, in that the effect of the higher temperatures are either nil or stimulatory. No short-term inhibitory effects were found even at 36 degrees C.

2.1708, THE ECOLOGICAL EFFECTS OF THERMAL STRESS ON CERTAIN NEUROENDOCRINE-PHYSIOLOGICAL SYSTEMS OF SELECTED AQUATIC ANIMALS

A.S. TOMBES, Clemson University, School of Agriculture, *Clemson, South Carolina* 29631

This study will involve laboratory and field investigations on a vertebrate (fish) and on several invertebrates (aquatic insect larvae) to determine the impact of sub-lethal thermal stress on the organisms mediated by the neuroendocrine-physiological systems.

Field aspects will involve the determination of densities, growth rates, and seasonal positioning of life cycle stages both away from the area of heat discharge and within the area of thermal effluent. Laboratory studies will monitor the organisms' responses to specific levels and durations of thermal stress and various photoperiods. Initially the histology will be described of the neuroendocrine system. This will be followed by an experimental phase where sub-lethal levels of thermal stress will be introduced to the animals. If any specific changes occur in the neuroendocrine system they will be identified and related to the duration and time of exposure to different temperature levels and, in turn, will be correlated with possible ecological effects.

Laboratory data will be related to the possible need for improved water quality and waste disposal standards of nuclear reactors, by determining the extent to which a body of water can absorb thermally enriched effluent without influencing the lake's ecosystem beyond that level which has been determined to be ecologically and economically permissible.

Hopefully the combination of organismal and ecological levels of study will provide a bioassay surveillance or predictive system for sub- lethal thermal loads.

2.1710, WATER POLLUTION INVESTIGATION, BATTLE CREEK, SOUTH DAKOTA

R.D. GLOVER, State Dept. of Game Fish & Pk., *Pierre, South Dakota* 57501

Objectives: To document the benthic fauna populations.

Procedures: The benthic fauna sampling program will be the only facet of this project which will be continued. Sampling will be conducted at previously described stations and information collected will be used to supplement existing data.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1711, EFFECTS OF DEVELOPMENT ON WATER QUALITY

M.A. CHURCHILL, U.S. Tennessee Valley Auth., Div. of Environ. Res. & Dev., *Chattanooga, Tennessee* 37401

Provide a means for predicting the quality of the water to be released through low-level outlets of proposed impoundments. A regression equation has been fitted to data collected routinely for a number of years for other purposes. This equation allows the prediction of dissolved-oxygen concentrations in the releases throughout the year. As more extensive data on water quality and on movement of water into, through, and out of reservoirs are obtained, a rational prediction equation will be developed that will apply to a wider range of conditions than does the regression equation. Techniques for predicting concentrations of iron, manganese, plankton, coliform organisms, and other properties are also sought. Means of raising dissolved-oxygen concentrations by modifying the design or operation of discharge-control structures are under evaluation.

2. WATER QUALITY

SUPPORTED BY U.S. Tennessee Valley Auth.

2.1712, EFFECTS OF TEMPERATURE ON AQUATIC LIFE

M.A. CHURCHILL, U.S. Tennessee Valley Auth., Div. of Environ. Res. & Dev., *Chattanooga, Tennessee* 37401

Research is being conducted to provide sound technical bases for development of realistic temperature control criteria for maintenance and propagation of aquatic life. The effects of temperature on the quality and quantity of economically important species and their supporting food chain will be studied. Laboratory studies have been initiated to determine lethal temperatures for nine species of locally important fish and several fish-food organisms. It is planned to construct eight large channels simulating natural waterways. In these channels, normal biotic situations will prevail except for water temperatures. Six of the channels will contain lake water heated to maintain desired elevated temperatures. Two channels will serve as biological controls and will contain water of ambient stream temperature.

SUPPORTED BY U.S. Tennessee Valley Auth.

2.1713, EFFECTS OF IMPOUNDMENT ON WATER QUALITY

M.A. CHURCHILL, U.S. Tennessee Valley Auth., Div. of Environ. Res. & Dev., *Chattanooga, Tennessee* 37401

Problem. To develop engineering methods which can be used in planning, designing, and operating river and reservoir water control structures associated with multi-purpose water resource projects for management of water quality and quantity. The water quality management problem arises from the discharge of hypolimnetic water during periods of reservoir stratification having quality problems associated with low temperatures, low dissolved oxygen, and objectionable quantities of iron and manganese. These water quality problems are associated with low level outlets in existing and proposed water control structures.

Method. The physical, chemical, and biological factors which cause objectionable changes in water quality during periods of reservoir stratification are to be qualitatively and quantitatively assessed. The resulting knowledge is to be used to develop a model which will allow temporal and spatial changes in the water quality parameters of temperatures and dissolved oxygen to be predicted within an impoundment. This model is necessary for evaluating the effectiveness and feasibility of proposed design and operational changes to improve water quality of discharged water.

The research method has involved frequent field surveys and laboratory analyses of water quality parameters of interest over several years during stratification of reservoirs in eastern Tennessee. Data produced are being studied extensively to gain insight into the relationships between physical, chemical, and biological factors and the associated water quality changes. These relationships will then be used to develop a predictive model for changes in water quality due to impoundment.

SUPPORTED BY U.S. Tennessee Valley Auth.

2.1714, EVALUATION OF FACTORS AFFECTING SPAWNING OF DALE HOLLOW WHITE BASS

B.L. RIDLEY, Tennessee Technological Univ., School of Arts, *Cookeville, Tennessee* 38501

Objectives: Determination of spawning areas; temperature and time of year at spawning; and sex ratio at the spawning areas. An attempt will be made to assess the effects of coal mine drainage on spawning. An attempt will also be made to determine if separate spawning populations exist in Dale Hollow Reservoir.

Procedures: Spawning areas will be determined along with the time of year and the temperature at spawning time. The sex ratio at the spawning areas will be recorded. It is known that the east fork of the Obey River is used some as a spawning ground and that the east fork is polluted by coal mine drainage. An attempt will be made to determine how severe this pollution affects the spawning white bass and to determine if this is a limiting factor to their spawning. Water quality data presently being collected on the east fork by another researcher. If time permits, it will be determined if there are separate spawning populations of white bass within Dale Hollow Reservoir, and if the same fish use the same spawning grounds from year to year. This will be accomplished by fin clipping fish for future recognition upon recapture.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1715, COAL STRIP MINE WATERSHED DEMONSTRATION--JACKSON COUNTY, ALABAMA

K.J. SEIGWORTH, U.S. Tennessee Valley Auth., *Knoxville, Tennessee* 37902

The demonstration-research watershed was established in June 1968 to determine how area coal strip-mining and subsequent reclamation practices will affect the water resource and aquatic life of a small 136-acre watershed in northeast Alabama. Farco Mining Company is cooperating in the study.

Hydrologic observations include precipitation, streamflow, water temperature, and sediment. Samples for complete water-quality are being secured. In addition, ecological studies of aquatic life in and adjacent to the stream are being conducted.

The project will be conducted in three phases: (1) a calibration period of approximately two years, (2) an action phase during which about 50 percent of the watershed will be mined, and (3) a recovery period following reclamation work on the stripped areas. Current reclamation provisions included in TVA coal contracts will be reviewed in the light of data obtained from the project.

SUPPORTED BY U.S. Tennessee Valley Auth.

2.1716, NORTH FORK CITICO CREEK WATERSHED RESEARCH

P.C. SPATH, U.S. Tennessee Valley Auth., *Knoxville, Tennessee* 37902

Research established in 1960 cooperatively by TVA, U. S. Forest Service, and Tennessee State Game and Fish Commission in Cherokee National Forest to determine the effect of high-standard, multiple purpose forest management on watershed hydrology and stream biology. The well-managed, completely forested Appalachian Mountain watershed has an area of 7 square miles and ranges in elevation from 2000 to 5000 feet above sea level.

Hydrologic observations include precipitation, streamflow, air and water temperatures, relative humidity, sediment and quarterly water- quality samples for mineral analysis. Forest, soil, and hydrologic condition surveys were made. Wildlife habitat surveys will be made and browse condition and trend or change in plant species composition observed. Stream biology investigations include sampling of bottom fauna, growth rate of wild rainbow trout, and determination of fish population.

The research involves two phases. The calibration phase involves the determination of the hydrologic characteristics of the watershed under existing conditions. The second phase, called the action phase, involves determining the changes in the hydrologic characteristics of the watershed caused by the construction of access roads to selected timber cutting areas and by the cutting and removal of timber in the selected areas. The calibration phase was completed in 1965. The action phase was begun in 1966 when construction was started on an access road to the first timber sales area. Construction of this access road was completed in 1967. Timber cutting began in the spring of 1968 and was completed in the first timber sale area in the fall of 1969. A system of roads is planned for additional timber harvesting operations and to provide access to proposed areas.

SUPPORTED BY U.S. Tennessee Valley Auth.

2.1717, EFFECTS OF WATER POLLUTION ON ZOOPLANKTON

D.L. BUNTING, Univ. of Tennessee, Graduate School, *Knoxville, Tennessee* 37916

Because of the lack of information dealing with the tolerances and reproductive rates of zooplankton species in polluted waters, it is planned to 1) provide estimates of the median

tolerance limits of planktonic rotifers, cladocerans, and copepods to insecticides and toxic materials found in domestic and industrial wastes, 2) to measure the effect of sublethal concentrations of toxic wastes on the reproductive rates of natural and laboratory populations of planktonic rotifers, cladocerans, and copepods, and 3) to determine the growth patterns of several important planktonic rotifers, so that immature specimens may be segregated from adults in the egg/female/day estimates of reproduction. It is expected that the median tolerance limits based on long term studies will contribute to the study of water quality criteria. And that the knowledge of tolerances and reproductive rates along with critical study of standing crops will further the understanding of changes in community structure brought about by the addition of toxic materials to natural water.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1718, HIGH ANALYSIS FERTILIZER INVESTIGATIONS - FISHERIES
B.D. JACO, U.S. Tennessee Valley Auth., *Norris, Tennessee* 37828

A comprehensive test of the effect of high-analysis plant nutrient application on fish production, particularly sport fish reproduction and survival, in limited areas of large TVA reservoirs. This project completed; results show:

Increasing sport fishing in selected coves of a deep reservoir through application of inorganic fertilizer during one growing season does not appear to be practical. The fertilizer produced little lasting increase in nutrients in the water of the coves. Most of it presumably sank into the mud or was sluiced out of the coves.

Fertilization increases the number of bottom organisms and zooplankton but there was no significant change in numbers, size, species composition, or survival of fish. Temperature and oxygen profiles coupled with the physical characteristics (directional axis of coves in relation to main creek and cove depth and length) suggest that the age of the water may be very significant in increasing production in coves.

The exact effect of fertilizer still remains unknown since the amount of fertilizer loss to sinking and sluicing could not be measured. But one thing seems clear: the measured increase in production was due to only a small fraction of the total application.

SUPPORTED BY U.S. Tennessee Valley Auth.

2.1719, COAL STRIP MINE WATERSHED STUDY
D.H. SCANLON, U.S. Tennessee Valley Auth., Div. of For. Fish. & Wlf. Dev., *Norris, Tennessee* 37828

A watershed project to determine how coal strip mining and subsequent reclamation affects water quality and stream ecology. The 136-acre watershed under study is in Jackson County, Alabama. Over half the watershed will be stripped for coal in 1970. Hydrologic data collection began in May 1968 upon completion of the weir and project instrumentation, and will continue for two years prior to mining, during the mining operation, and for ten years after reclamation. Biologists began sampling the stream and streamside flora and fauna in February 1968, and will continue periodic measurements through life of the study to identify ecological change.

SUPPORTED BY U.S. Tennessee Valley Auth.

2.1720, THERMAL ENRICHMENT STUDIES
S.F. AUERBACH, U.S. Atomic Energy Commission, Ecological Sciences Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

The objectives of these studies is to develop a capability for predicting the impact of man-made thermal modifications to freshwater ecosystems. Operation of power reactors can affect water temperatures when surface waters are used for cooling and the use of cooling towers can affect water quality through consumptive use of water for cooling purposes which may result in a concentration of chemicals, including radionuclides, in the released water. Research will include a closely integrated program of simultaneous field and laboratory investigation related to the needs of engineering design in power plant construction and siting. The behavioral responses of fish to temperature changes will be considered as they relate to predation, migration, spawning and survival of the population. Warm water species of fish, such as largemouth bass and channel catfish and associated food organisms, will be the experimental animals.

A simultaneous effort will be the development of systems models incorporating different temperature, nutrient regimes and stresses. These models would form a basis for predicting the ecological consequences of thermal additions to various aquatic habitats. The models will also serve as a guide in the experimental studies.

Preliminary results showed that the excretion rates of Cs 137 and 65 Zn were directly related to temperature within the range of 10 to 30 C. However, the Q sub 10 law does not appear to offer a good method of extrapolating to biological half-lives at the extreme temperature ranges. Similar studies of 32P metabolism showed that the biological half-life of 32P decreased from 58 days at 9.3 C to 3.7 days at 19.3 C. Assimilation of 32P from the gut was 51 per cent at 19.3 C and 30 to 38 per cent at the lower temperatures.

SUPPORTED BY U.S. Atomic Energy Commission

2.1721, ENVIRONMENTAL QUALITY STUDY PROJECT - UTILIZATION OF WASTE HEAT
S.E. BEALL, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

The conversion of energy to produce electricity in a thermal plant results in 60-70% of the energy being dispersed to the environment, usually by direct water cooling. The goal of this work is to use an energy systems approach to attempt to utilize this waste heat and simultaneously to lessen the environmental insult of the heated water. Possible uses include urban, industrial, agricultural, and aquacultural. The latter two have more immediate promise. Urban uses are very promising in the context of new or renovated cities. Our objective is to determine whether there are economically viable uses, conditions under which they may be developed, and the enviromental consequences of such developments. We utilize prior experience gained from AEC/HUD studies at ORNL and also the work of the Middle East Study Group. Experimental work, virtually absent in the past, is expected to commence in FY 71.

Results to date: We have finished design of a facility for shrimp production and an economic study of the system as a part of a major, shore-based energy center and have completed conceptual design of a greenhouse system utilizing heated water for heating and cooling and associated economic studies. We organized a working conference on prospects for beneficial use of waste heat, attended by representatives of government, industry, utilities, and universities.

SUPPORTED BY U.S. Atomic Energy Commission

2.1722, AGING AND IMMUNE COMPETENCE-EFFECT OF ENVIRONMENT ON IMMUNE COMPETENCE
T. MAKINODAN, U.S. Atomic Energy Commission, Biology Division, *Oak Ridge, Tennessee* 37830 (W-7405-ENG-26)

Since we began our study on aging of the immune system over ten years ago, dramatic improvements were made in the operation of animal care. Thus, by today's standard, a conventional mouse farm of a decade ago would probably be rated as a substandard farm. We do not know to what extent improvement in animal care may have influenced our earlier findings. Since studies on the effect of substandard environment on life span and immunologic activity of mice have never been made, we have undertaken this problem.

Five six-weeks old, 'specific-pathogen-free' BC3 F sub1 mice purchased from Cumberland View Farm were reared in either a conventional (clean) or a substandard (dirty) farm. The diet was the same. Those in the clean farm received clean pans twice a week and chlorinated water (16 parts per million) three times a week, and those in the dirty farm received clean pans only once a week, and tap water twice a week. The water bottles in the dirty farm were purposely contaminated with viable Salmonella and Pseudomonas soon after we initiated this project. Both primary and secondary antibody-forming capacities are being assessed.

Results: The results revealed that no significant farm effect was detected immunologically and no striking difference in the life span was noted; e.g., the median life span was comparable. These results indicate that 'specific-pathogen-free', postweaning mice can adapt themselves to a substandard environment without any long term effects on their immune system and life span. These studies are being expanded to include aged mice that were bred in their respective farms.

SUPPORTED BY U.S. Atomic Energy Commission

2.1723, ENVIRONMENTAL QUALITY STUDY PROJECT - THERMAL DISCHARGES AND EFFECTS STUDIES
M.M. YAROSH, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

Objective of this work is to develop a program of work designed to provide the basis for regulation of thermal effluents, to minimize their environmental impact by careful and improved design of inlets, outfalls and cooling towers, and to develop tools for regional planning of power plants. There is much already known about thermal discharges and aquatic effects. However there are large areas of insufficient knowledge that need to be bolstered with specific research, especially in thermal effects in the biosphere, analytical models for thermal water plumes, and wet and dry cooling tower design and meteorology. Our procedure is a combination of state-of-the-art survey, identification of needed R&D, ordering of research priorities, and experimental and theoretical studies. Results: A state-of-the-art review on atmospheric effects of cooling towers was largely completed. An evaluation of thermal baseline studies by utilities on docketed reactor sites was made. A study was undertaken of the current and projected research programs in the thermal area by approximately 200 federal and state agencies, utilities, universities, and private industries. A task force was assembled to prepare a Program Plan on Thermal Discharges and Effects (first draft due July 1970).

2.1724, THE DISTRIBUTION AND DENSITY OF MACROBENTHOS IN LAKE ARLINGTON, TEXAS
T.R. HELLIER, Univ. of Texas, Graduate School, *Arlington, Texas* 76010

It is proposed in this study to determine the qualitative and quantitative distribution of benthic invertebrates in Lake Arlington, Texas with emphasis being placed upon horizontal distribution and seasonal succession, and the possible effects of heated effluent upon the aquatic community. Collections will cover a period of at least one calendar year, thus permitting an analysis of the seasonal aspect of benthic distribution. By correlation of benthic samples with analyses of temperature, oxygen concentration, bottom type and other physicochemical characteristics, it is hoped that an understanding of temperature-related influences upon the benthic community may be developed.

SUPPORTED BY Texas Electric Service Company - Texas

2.1725, LARGEMOUTH BASS REPRODUCTION STUDY
K.W. GHOLSON, State Parks & Wildlife Dept., *Austin, Texas* 78701

Objective: To identify factors concerned with sewage effluent and hydroelectric cooling which inhibit largemouth bass reproduction.

Procedures: 1. Adult bass will be dissected and sexual development recorded along with length, weight, and other pertinent data. 2. Spawning areas will be located in Calaveras Lake, spawning activity observed, and information recorded. 3. Fertilized largemouth bass eggs will be removed from nests and incubated in the laboratory and/or state fish hatchery. These eggs and eventually produced fry will be observed for hatch-ability, development and survival. 4. Adult largemouth bass will be collected from Calaveras and Braunig Lakes and taken to a state fish hatchery and observed for spawning activity and success. 5. Monthly water temperatures will be recorded at established stations throughout the lake to establish a water temperature profile for Calaveras and Braunig Lakes. 6. During the first month of this segment, top and bottom water samples will be taken throughout the two lakes to determine water quality of the two reservoirs. Following, this, periodic samples will be collected to determine any changes which might occur in the lakes. 7. Quarterly core samples will be made at established stations to identify bottom deposits and to determine rate of desposit of organic detritus and other deposits on the bottom of the two lakes. 8. Pesticide residue analyses will be conducted on the following samples: a. Four water samples per lake monthly; b. Three bottom samples quarterly; c. Gonad, liver, and muscle tissue of four largemouth bass (2 males and 2 females) from each reservoir monthly.

2.1726, THE EFFECTS OF ENGINEERING PROJECTS ON THE ECOLOGY OF JONES BAY
R.B. JOHNSON, State Parks & Wildlife Dept., *Austin, Texas* 78701

Objectives: To study the ecology of Jones Bay prior to alteration and to evaluate the effects of the proposed Hitchcock extension of the Texas City Hurricane Protection Levee.

Procedures: The study will include description of the area, an analysis of bottom sediments, chemical and physical water quality, and species composition and abundance. The extent and quality of nursery habitat will be evaluated.

Representative stations will be established and sampled systematically in affected areas and in control sites. Catch per unit effort records will be maintained so that all work can be duplicated and compared. Sampling procedures will compare to those used in estuarine research by the Texas Parks and Wildlife Department and the Bureau of Commercial Fisheries Laboratory at Galveston.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.1727, THE EFFECTS OF ENGINEERING PROJECTS ON THE ECOLOGY OF MOSES LAKE
R.B. JOHNSON, State Parks & Wildlife Dept., *Austin, Texas* 78701

Objectives: To study the ecology of Moses Lake and compare data accrued prior to the construction of the Texas City Hurricane Protection Levee, and to evaluate the effects of levee alterations in progress.

Procedures: The study will include description of the area, an analysis of bottom sediments, chemical and physical water quality, and species composition and abundance. The extent and quality of nursery habitat will be evaluated.

Representative stations will be established and sampled systematically in affected areas and in control sites. Catch per unit effort records will be maintained so that all work can be duplicated and compared. Sampling procedures will compare to those used in estuarine research by the Texas Parks and Wildlife Department and the Bureau of Commercial Fisheries Laboratory at Galveston.

2.1728, THERMAL STUDY IN WILKES RESERVOIR
J.E. TOOLE, State Parks & Wildlife Dept., *Austin, Texas* 78701

P.S. Objective: To determine the effects of hydroelectric thermal effluent on aquatic life in Wilkes Reservoir.

Procedures: All field data from previous segments will be analyzed and compiled for publication or final report as findings warrant.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1729, BOTTOM SLUDGE ACCUMULATION AND OXYGEN DEMAND IN A POLLUTED ESTUARY
R.W. HANN, Texas A & M University System, Sea Grant Program Office, *College Station, Texas* 77843

Two major components in the analysis of the water quality in an estuary are the pollutant removal rate by sedimentation and the resultant oxygen demand of the bottom deposits. This project involves a study of solids balance and the oxygen balance of an

arm of the Houston Ship Channel to develop methodology for evaluating these parameters. The study includes both field evaluation of parameters and analytical computer simulation of the phenomena taking place.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1730, HEAVY METALS AND LOCOMOTION IN FISH
H. KLEEREKOPER, Texas A & M University System, School of Science, *College Station, Texas* 77843

Locomotor behavior in response to gradients of sublethal concentrations of heavy metals in an open field situation is studied. Locomotion is monitored by means of a matrix of 2000 photocells, embedded in the floor of a tank measuring 6.0 x 6.0 x 0.6 m. The matrix is part of an electronic interface with a computer or line and data- processing equipment. Gradients of temperature, flow, and chemical conditions are controlled by feedback and servo-mechanisms. Three dimensional profiles of temperature and chemical gradients are monitored with arrays of thermistors and conductivity cells.

Velocity of locomotion, frequency distribution of angles of turns, absolute directions, distances swum, areas of preference or avoidance are computed and analyzed in relation to the gradients of copper and zinc ions in various conditions of temperature and flow.

The investigation started on July 1, 1969, was continued on July 1, 1970, and is expected to be completed by June 1972.

2.1731, TOXICITY OF METALS TO MARINE PHYTOPLANKTON CULTURES
W.B. WILSON, Texas A & M University System, Graduate School, *College Station, Texas* 77843

The objectives of the proposed work are as follows: (1) Determine the acute toxicity of eight metals (V, Cr, Mo, Fe, Ni, Cu, Ag, and Hg) to cultures of three typically estuarine phytoplankton species (Cyclotella nana, Gymnodinium splendens and Isochrysis galbana) in media of various salinities; (2) Determine the acute toxicity of these metals to these organisms at five temperature levels and the interaction of temperature and salinity with the toxicity of these metals; (3) To determine whether or not organisms subjected to sub-acute toxic levels of these metals in combination with various temperatures and salinities will subsequently grow at a standard rate and determine the effects of a continuously maintained non-acutely toxic concentration of each metal to one or more of these organisms. For acute toxicity tests, it is proposed that bacteria-free and unialgal cultures of these three organisms grown in batch cultures will be subjected to various concentrations of these eight metals. The effects will be evaluated after 1, 24 and 48 hours by microscopic examination and culture enumeration. The combined effects of temperature, salinity and metals will also be evaluated by determining the C14 uptake. Chronic toxicity of metals will be evaluated in a continuous flow culture device.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1732, EFFECTS OF SELECTED POLLUTANTS ON CERTAIN GAME AND ROUGH FISH
C.E. MURPHY, Texas Christian University, Graduate School, *Fort Worth, Texas* 76129

The objectives of this project are to (1) ascertain the relative toxicity (TLm) of certain local industrial wastes for selected game and rough fish, (2) determine the influence of certain concentrations of specific industrial wastes on growth and development of selected game and rough fish, (3) gain information for computing a safe rate effluent discharge for certain industrial waste effluents.

This work will be carried out along the upper part of the Trinity River which serves as the sole avenue for transporting domestic and industrial wastes from a highly industrialized region. Initial attention will be given to effluents which bypass municipal treatment systems and are discharged directly into the river. Water samples from the river will be collected and characterized to determine the nature of the water above and below the point of waste effluent will be collected and characterized and used in TLm determinations for selected species of fish. Spawn will be exposed under the same conditions as the fish to detect effects on growth and development. All testing in the laboratory will be carried out using continuous flow systems.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1733, A STUDY OF THE EFFECTS OF DESALINATION PLANT EFFLUENTS ON MARINE BENTHIC ORGANISMS
E.F. MANDELLI, Dow Chemical Company, *Freeport, Texas* 77541

The objective of this research program is to determine the effects of increased salinities, temperatures and concentration of heavy metals, particularly copper, on the growth and survival of commercially important coastal marine benthic organisms.

Such information is of fundamental importance in the design of outfall systems fot the proper disposal of waste brine from desalination operations in coastal and estuarine areas.

The program was initiated during 1969, with long-term bioassay test (seasonal) through simulated in-situ experiments on juvenile and adult specimens of the American oyster Crassostrea virginica.

The effects of the desalting brine-cooling water mixtures are also being evaluated on early stages (eggs and larvae) of C. virginica as well as the postlarval stages of the brown and white shrimp Penaeus aztecus and P. setiferus.

2.1736, THE RELATIONSHIP OF ELECTRIC POWER STATION THERMAL CIRCULATION TO BIOLOGICAL PRODUCTIVITY OF RESERVOIRS
O.T. LIND, Baylor University, Graduate School, *Waco, Texas* 76703

The Proposed Investigation will: 1. Confirm that phytoplankton photosynthesis is reduced by the circulation process, and will relate the quantity of this reduction in a new reservoir to volume circulated, number of operating generators, time of circulation, and temperature rise. 2. Determine if the process of power plant circulation has qualitative as well as quantitative (as demonstrated in a former investigation) effects upon the photosynthetic pigments of the phytoplankton. 3. Determine if reduced photosynthesis is due to altered metabolism of individual cells or reduction of total cell number, and determine if phytoplankton diversity is reduced. 4. Determine whether reduced photosynthesis is the direct effect of temperature, as suggested by the earlier study, or to inhibition or toxicity brought on by exposure to metal ions as the water is circulated through the system. 5. Determine if degradation and recycling or organic matter is accelerated by the circulation process. 6. Determine if fish growth and production is significantly increased in the heated water, with possible application of such growth increase to fish culture.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1737, BACTERIAL ADSORPTION ON SOILS
D.W. HENDRICKS, Utah State University, Utah Water Research Laboratory, *Logan, Utah* 84321

This work will focus upon the role of adsorption, as a mechanism in bacterial retention, in the flow of bacterial suspensions through soils. The project intends to be definitive in that all of the hypothesized factors that affect bacterial adsorption will be investigated. These factors include cell concentration temperature, chemical environment, and surface activity. By understanding and quantifying the fundamental removal mechanisms, predictions of bacterial movement through soils can be made. Other mechanisms of retention which will be investigated, but in a less exhaustive treatment, include sieving, gravitational sedimentation, and several other possibilities.

Such knowledge will allow rational assessments of the health hazards of groundwater recharge, shallow aquifer contamination, and proximity of septic tanks to wells.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1738, SHORELINE ENGINEERING STUDIES ON GREAT SALT LAKE
W.P. HEWITT, Univ. of Utah, State Geolog. & Min. Surv., *Salt Lake City, Utah* 84112

The object of this study is to determine the effect of currents, storm waves, and heavy brine on engineering structures that might be built on Great Salt Lake, or upon its shores. A contour-map of the brine-lake bed contact is to be built, currents are to be studied and reefs are to be plotted.

Status: Lakewide survey involving current measurements, water depths, water temperatures and water densities are under way. Photography of lake, obtained cooperatively in 1965 and in 1966 with U.S. Geological Survey, has been studied for reef distribution and shoreline features.

Study of Kennecott Copper Corporation's tailings dike in the lake has been completed.

Isolated current measurements have been made but the major lakewide current survey has not yet commenced.

Water temperatures and density measurements are presently in progress in conjunction with our water sampling program.

Reef morphology is also currently being studied as part of the over-all continuing investigation of bottom sediments.

2.1740, PROBLEMS RELATED TO THE EFFECTS OF HEATED DISCHARGES FROM THERMAL POWER PLANTS
R.C. TUCKER, U.S. Natl. Water Commission, *Arlington, Virginia* 22203

The objective of the research is to: 1. Assess the magnitude of the thermal effects problem and cooling water requirements for thermal power generation. 2. Consider what impact changing life styles may have on the problem. 3. Assess the environmental effects of heated discharges, this is to include both the effects on aquatic biota as well as stream uses. 4. Assess what significance beneficial uses of waste heat may have on reducing the thermal pollution problem. 5. Study the effects of alternative methods of heat dissipation. 6. Consider possible technological developments in power generation and condenser cooling and their possible impact on the problem. 7. Consider the present status of the art in thermal effects and recommend further study in the form of priorities for study in those areas where knowledge appears most deficient. 8. Consider the present institutional arrangements and policies dealing with thermal effects and to recommend improvements where felt necessary. 9. Propose methods for bringing the expertise of ecologists and environmentalists to the siting of power plants. 10. Propose methods for power plant siting.

The plan of study includes individual efforts by the principal investigator as well as input from a number of staff and contract studies being carried out for the NWC. The study will also include meeting with a panel of consultants. This project was initiated in FY 1970 and will terminate FY 1972.

SUPPORTED BY U.S. National Wtr. Comm. - Arlington, Va

2.1741, IDENTIFYING ENVIRONMENTAL QUALITY ATTRIBUTES IN WATER RESOURCES
R.E. VINCENT, U.S. Natl. Water Commission, *Arlington, Virginia* 22203

The overall objective of the study is to provide information on the effects--both adverse and favorable--of water resource development upon the environment, including its impact upon scenic beauty, historic and wild areas, fish and wildlife resources and recreational opportunities, and to develop means for weighing such effects against possible material gains. The study has been divided into four parts: (a) the role of environmental quality in maintaining a balance of values in water development; (b) the role and aesthetic value of water in landscape design; (c) the classification and designation of water for specific uses; and (d) recycling and ecosystem response to water manipulation. Each of these parts represents a discrete research task to be accomplished separately under contract. The overall study will evaluate and synthesize the results of the contract studies.

2.1743, THE EFFECTS OF HEATED WASTE WATERS UPON MICROBIAL COMMUNITIES
J. CAIRNS, Virginia Polytechnic Institute, Graduate School, *Blacksburg, Virginia* 24061

One of the major water management problems is created by the discharge of heated waste waters from steam electric generating plants. Singer estimates that one quarter of all surface waters in continental United States will be used for cooling in 1985. Clearly, some basic decisions regarding the management of discharge waters should be made as soon as possible. Unfortunately, very little information concerning effects of heated discharge waters is now available, particularly where fresh-water protozoan communities are concerned. The specific aim of this project is to extend and expand the information regarding effects of heated discharge waters upon microbial communities, particularly protozoans, with some emphasis upon aquaria fungi and algal relationships. This study will initially be divided into two broad areas. 1. Simulation of the passage of water through a condensing system to determine the effect of this exposure upon unicellular organisms 2. The effect of simulated passage through the condenser upon the microbial system below the discharge point.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1744, EFFECTS OF TOXICANTS UPON FISH MOVEMENT PATTERNS
J. CAIRNS, Virginia Polytechnic Institute, Graduate School, *Blacksburg, Virginia* 24061

The purpose of this research is to develop a rapid means of assessing non-lethal effects of toxicants upon fishes, using changes in movement patterns during exposure to toxicants and to relate the 'safe' or 'no response' concentrations so estimated to longer term functions such as growth and reproductive success. The apparatus which will be used to measure the movement patterns of the test species is measured by light beam interruption. The long range goals include the establishment of a pilot study in which the movement detecting apparatus will be incorporated into an industry's effluent to be used as a biological monitoring device.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1745, TOXICANTS AND THE EKG AND RESPIRATION OF FISH
J. CAIRNS, Virginia Polytechnic Institute, Graduate School, *Blacksburg, Virginia* 24061

One of the most critical needs for industrial pollution control is a biological monitoring technique that can provide continual information feedback on the toxicity of the waste. Most biological assessment techniques either estimate how much waste can be tolerated on the basis of bioassays (usually involving a few samples of waste, and using death of the test organisms as indication of response) or how much damage, if any, has occurred after the waste has been placed in the receiving stream (biological surveys, etc.). These are worthwhile assessments but they do not provide rapid and continual information on waste quality.

The purpose of this research is to develop a rapid means of assessing the nonlethal effects of toxicants upon fishes using changes in the electrical signals from the heart and breathing muscles during exposure. The apparatus consists of plexiglas tubes in which individual fish are confined. A continuous flow of synthetic dilution water containing various concentrations of toxicants can be passed through the tubes. The tubes are designed so that the heart and breathing signals are recorded on a Grass Polygraph.

The 'safe' or 'no response' concentrations determined by this echnique will be related to longer term functions such as growth ind reproductive success.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1746, STREAM FAUNAL RECOVERY AFTER MANGANESE STRIP-MINE RECLAMATION
K.B. CUMMING, Virginia Polytechnic Institute, School of Agriculture, *Blacksburg, Virginia* 24061

The objectives of this proposed research are to monitor water quality in four tributaries which represent various stages of recovery from strip-mine pollution and to conduct studies on the chronic physiological action of mine effluent on fishes of these waters. The change in water quality following different stages of reclamation work on National Forest lands will be used to measure the rate of stream recovery as well as to document the continuing damage caused by unreclaimed mines. The sublethal action of suspended matter and manganese metal will be described as they affect growth rate and condition index of two representative species, rainbow trout and white sucker, in this watershed. The growth studies will be carried out at the Buller Fish Cultural Station near Marion, Virginia.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1747, SOME EFFECTS OF THE RECENT INTRODUCTION OF HARD WATER INTO THE WATER SUPPLY RESERVOIR OF CARVIN COVE, VIRGINIA
K.B. CUMMING, Virginia Polytechnic Institute, School of Agriculture, *Blacksburg, Virginia* 24061

The relationship between fish production and the physical and chemical factors in lake environments have been of considerable interest to limnologists for some years. Recent introductions of hard water into Carvin Cove Reservoir have affected the overall physical and chemical properties of the reservoir. The objectives of the present study are: 1. To document the change that has taken place over the last four years in chemical quality of the water. 2. To examine the effects of this change upon distribution of bottom fauna. 3. To study the effect of the hard water upon productivity, distributions, species composition, and relative abundance of fish population from the reservoir.

SUPPORTED BY Virginia State Government

2.1748, BIOLOGY OF ANADROMOUS ALOSIDS
J. DAVIS, Virginia Inst. of Marine Sci., *Gloucester, Virginia*

Objectives: 1. Obtain a collection of data on which to base estimates of the composition of the spawning run of alosids in 1969 and the mortality rates of the species. 2. Estimate the catch of each species of Alosa in each river system. 3. Find the spawning sites and nurseries of alosid fishes in the James River system. 4. Investigate tolerance to domestic and industrial wastes in the James River.

Procedures: 1. Age and spawning history will be determined by counting rings and spawning checks on scales. 2. Catch records will be obtained from a sample of each type of gear in each river and the total number of gears of each type will be counted monthly. Total catch will be estimated by multiplying the average catch of the sample gears by the total number of units of gear. 3. The mainstream and its tributaries will be sampled for eggs, ripe fish, and newly hatched larvae. Presence of any of these will indicate a spawning area. Areas in which young fish are caught will be considered to be nurseries. 4. Tolerance will be measured both by standard laboratory techniques and by monitoring the environment before, during, and after fish kills which are expected to occur.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.1749, EFFECTS OF POLLUTANTS ON SUBMARINE PLANT SYNECOLOGY
M.A. DUBE, Western Wash. State College, Graduate School, *Bellingham, Washington* 98225

The purpose of this study is to gain an understanding of the dynamics of subtidal marine plant communities which are exposed to industrial waste outfall as compared to the dynamics of communities located in waters carrying less industrial areas before and after the development of the industrial installation. Communities closer to the source of industrial waste will be contrasted with those farther away to determine basic differences in (a) plant community structure, (b) productivity of the plant community, (c) the reproductive output of the plants, and (d) plant successional pattern. For example, it may be found that a community which is affected by pollution is arrested in a condition resembling an early stage in the successional development of an undisturbed community.

An attempt will be made to interpret differences in community dynamics in terms of differences in environmental factors by comparing at each site (a) the degree of chemical enrichment and concentration of suspended particles in the water, (b) the degree of siltation of the plants and substrate, and (c) the role of primary consumers. Controlled experiments will be run when possible to determine the separate effects of these factors.

2.1750, METABOLIC ROLE OF INORGANIC ELEMENTS IN SALMONIDS - 15 - EFFECT OF TOXIC LEVELS OF COPPER OR ENZYME ACTIVITIES
W.S. ZAUGG, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Cook, Washington*

Determine various enzyme activities in organs which accumulate copper when fish are subjected to toxic levels of this element in their aquatic environment and/or diet. Activities to be tested include ATP phosphohydrolase and oxidative phosphorylation.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1751, ENERGY-DEPENDENT ION MOVEMENTS AND ACCUMULATION IN MEMBRANES OF SALMONID TISSUES

W.S. ZAUGG, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Cook, Washington*

Mitochondria will be isolated from gill, liver and kidney tissues of salmonids and examined for their ability to accumulate ions (Ca plus plus, K plus etc,) by energy-dependent mechanisms. Energy will be generated by mitochondrial oxidative reactions or by addition of ATP. ATP dependent accumulation of ions by microsomes from these tissues will also be studied. Samples will be taken from fish maintained in fresh water and compared to fish subjected to varying times of exposure to sea water. The effect of a number of stream pollutants on these activities will be studied.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1752, ECOLOGICAL CHARACTERISTICS OF THE COLUMBIA RIVER

C.E. CUSHING, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The objective of this study is the acquisition of data on biological, chemical, and physical factors for the Columbia River and the determination of their inter-relationships. Basic parameters are being determined to obtain estimates of energy transfer within the ecosystem. These include the determination of species compostion, biomass, and stable element composition of the dominant species of plankton, benthos, and fish. Concurrent with the biological sampling program, physical measurements will be made of current speed, water temperature, and characterization of the bottom substrata. Hanford reactor effluent water contains all the fission products plus activation products produced by neutron irradiation of river water constituents. The river ecosystem is, therefore, excellent for defining the relative and absolute behavior of the radionuclides and stable counterparts, basic chemical and radiochemical measurements made are fundamental to studies of the biogeochemical interactions with the sediments and biota of the river.

Results: Methods were developed which involve the concentration of river water particulates suspended, their isolation and the determination of particle size distribution in small quantities of samples. About 20 elements were measured at five ecologically significant times of the year by neutron diffraction, and six additional elements measured at monthly intervals by flame photometry, atomic absorption, and colorimetry. Over 85% of the total intact strontium sorption measured in the spring was attributable to the 2.0 mu fraction, whereas approximately 40% of the strontium sorption was attributed to particulates 0.5 mu in diameter (e.g., soluble).

SUPPORTED BY U.S. Atomic Energy Commission

2.1753, FINE STRUCTURAL EFFECTS OF TEMPERATURE IN FISH

J.C. HAMPTON, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

Previous work temperature effects in this laboratory demonstrated a shift in metabolism during acclimation to changes in water temperature. Liver and muscle were used as model organs and some fine structural changes in liver were correlated with the biochemical data. The sensing mechanism, or pathway, which mediates temperature acclimation in fish is unknown but certain organs, the hypothalamus, lateral line system, swim bladder and gills, are suspect because they function in sensing and initiating responses to environmental changes. These organs in the trout are studied for possible fine structural changes at temperatures ranging from 7.5 degrees-30 degrees C. Autoradiographic studies on cell turnover and protein synthesis in the organs listed and in liver during acclimation are made. Changes in the relative abundance of glycogen and mitochondria in muscle as well as in the actin and myosin filaments are evaluated at temperatures between 7.5 degrees C and 30 degrees C.

Results to date: A comparative study of red and white muscle fine structure was completed on tissues from trout acclimated to 7.5 degrees C. The results show only minor differences, if any in sarcomere length, and dimensions of filaments, but a significant increase in the number of mitochondria and the amount of glycogen in red muscle as compared with white muscle.

SUPPORTED BY U.S. Atomic Energy Commission

2.1754, SIMULATION MODELING OF THERMAL EFFECTS ON SELECTED RIVER SYSTEMS

R.T. JASKE, Battelle Memorial Institute, *Richland, Washington* 99352

This program consists of the application of digital simulation program originally developed for the investigation and prediction of Columbia River water quality, primarily temperature, both above and below the Hanford plant, to perform water quality predictions associated with the erection or planning for nuclear electrical generating facilities in critical major river basin areas. These critical areas, or marketing regions would be selected by the Div. of RD&T in response to current licensing needs and other predictions.

During FY 1968 it is proposed to complete simulation tests of the Illinois and Deerfield Rivers where major facilities are currently in operation. In addition, reports of the estimated effects of the Dresden 2 and 3 plants currently under construction down to river mile 80 are planned. A major regional system, such as the entire upper Mississippi or the Ohio River Basin will be selected by RD&T for simulation prediction through the foreseeable future. This program was initiated in FY 1967 and is expected to be continued through FY 1971 on the basis of current planning.

SUPPORTED BY U.S. Atomic Energy Commisaion

2.1755, EXTENDED STUDIES RELATED TO CONSTRUCTION OF A POWER REACTOR NEAR KALAMA, WASHINGTON

R.T. JASKE, Battelle Memorial Institute, *Richland, Washington* 99352

This program is designed to supplement previous work performed for the PUD by Battelle-Northwest. The original study centered on predicting the dispersion of heated effluent from a power reactor using once through cooling. The primary objectives of this proposed research program are: 1) Examine the effect of direct dilution on the ecological community 2) Study the possible conflict of interest over the use of water by both hydro and thermal power facilities 3) Install meteorological equipment which will provide the substance for the safety analysis report necessary for the preparation of required construction permits.

Period 6/70 to Present: Because of the unsettled situation regarding the interpretation of standards, further research on the site has been reduced to the routine collection of temperature information at five stations on the Lower Columbia. A progress report dated September 1970 is available summarizing all information collected during the past 12 months.

Significant findings include 1) That a greater temperature differential exists laterally in the affected reach than would be caused by fully mixed effluent from a 1000 MW reactor cooled on a once through basis and 2) The temperature regimen of the Kalama River, a valuable tributary of the Columbia located just below the plant site, has a diurnal temperature range and order of magnitude greater than that of the Columbia during the months of June, July and early August.

Continuation of the temperature measurements is under consideration. Further action to develop a power reactor site at Kalama for once through cooling is not certain.

SUPPORTED BY Clark County Government - Washington

2.1756, EFFECT OF REACTOR EFFLUENT OF QUALITY OF COLUMBIA RIVER WATER

R.T. JASKE, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)1830)

The study concerns the dispersion of Hanford effluent in the Columbia from point of discharge to the estuary at River Mile 20, a reach of 375 miles. The primary objective is the identification of thermal release and interrelated effects including the develop-

ment of models for transport of heat and radionuclides within the system.

A simulation model of the three hydroelectric plants (Wanapum, Priest Rapids and McNary) and the Hanford Reach was developed in a cost analysis of improved regulation of the river to increase minimum flow in the vicinity of the Hanford reactors. The model was solved with the UMPIRE code. The constraints were: the total and partial power demand, rates of change of the nearest upstream pool, minimum flow rates, water balance on the reservoirs, generating capability, and pool heights.

Dispersion characteristics of the river between R. Miles 383 and 355 were analyzed by both remote sensing and physical contact sampling systems using dye as a tracer. The effect of effluent buoyancy on the lateral dispersion coefficient was studied empirically; the coefficient depends upon density differentials. Values for the longitudinal diffusion coefficient were 500 - 3000 sq.ft./sec for flow rates 80,000 - 130,000 cu.ft./sec.

Early summer and fall transects (1969) at the Oregon-Washington border were used to check the accuracy of the COL-HEAT simulation model and the extent of stratification and mixing in the reservoir under maximum solar thermal input. The model was then used to estimate the persistence to the border (M.308) of Hanford heat additions (M.382). Sixty-five percent or more of the river temperature increment between Priest Rapids Dam and Richland is dissipated in that reach; the remainder is weakly related to the weather in terms of yearly variations.

SUPPORTED BY U.S. Atomic Energy Commission

2.1757, HYDRO-ENVIRONMENTAL EVALUATION OF NUCLEAR POWER PLANTS
R.E. NAKATANI, Battelle Memorial Institute, *Richland, Washington* 99352

The purpose of this work is to identify and describe the critical hydro-environmental problems facing the nuclear power industry. The work is essentially a survey of existing conditions. Thirteen nuclear power and two fossil fuel plants having distinctive heat release conditions or methods were visited. A report of findings and recommended research and development has been prepared.

SUPPORTED BY U.S. Atomic Energy Commission

2.1758, EFFECTS OF MODIFICATIONS ON THE COLUMBIA RIVER
D.G. WATSON, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The objective of this work is to develop an understanding of the impact of man-made modifications on freshwater ecosystems. The need for realistic information in the field of thermal effects is essential for location of nuclear power plants with a minimum of damage to environmental quality. Determination of the basic thermal requirements of aquatic organisms is necessary for formulating sound water quality standards for the nation's waters in the face of a wide variety of environmental alterations. Existing knowledge does not allow an estimate of the biological cost of radionuclides in the environment to be determined. Communities and populations under natural conditions are of interest in this work. Rainbow trout and chinook salmon will be examined because of their commercial importance.

RESULTS: In behavioral studies, thermally shocked fish were found to be selectively preyed upon, above certain minimum thermal doses. Artificial laboratory channels, maintained above ambient river temperature, were used to measure the effects of thermal increments on productivity and species composition. Biomass turnover, as output and standing crop, provided estimates of relative productivities. Measurement of radiation dose to the benthic river communities was continued. Dose rates to the underside of the river substrate were about 25 percent less than to the upper surface.

SUPPORTED BY U.S. Atomic Energy Commission

2.1759, SIMULATION MODELING OF ENVIRONMENTAL EFFECTS OF THERMAL GENERATION
P. HOFMANN, Westinghouse Electric Corp., *Richland, Washington* 99352

The purpose of this work is to apply the digital simulation capability developed in connection with the use of Columbia River water for cooling the Hanford plutonium production reactors to other water bodies.

Reports entitled 'A Test Simulation of the Temperatures of the Deerfield River', BNWL-628; 'A Test Simulation of the Temperature of the Illinois River and a Prediction of the Effects of Dresden II and Dresden III Reactors, BNWL-728'; and 'Simulation Modeling of Thermal Effluents in an Irrigation System, BNWL-1277', have been published and are available from the Clearinghouse for Federal Scientific and Technical Information.

A lake temperature prediction model has been developed. This model will be tested using field data from the Great Lakes during FY 1972.

SUPPORTED BY U.S. Atomic Energy Commission

2.1760, REGIONAL MODELING OF SURFACE WATER TEMPERATURES FROM PROJECTED POWER GROWTH
D.E. PETERSON, Westinghouse Electric Corp., *Richland, Washington* 99352

Digital simulation programs developed at the Pacific Northwest Laboratory applicable to the Columbia River have been used to predict the impact of nuclear facility operation in major river-basin areas. Program outputs have included modifications based on plant operational experience for both normal and abnormal weather and flow conditions. Ultimate capabilities of given stream systems to support thermal generation concentrations have been and will be estimated.

Reports entitled 'A Test Simulation of Potential Effects of Thermal Power Plants on Streams in the Upper Mississippi River Basin, BNWL-999' and 'Potential Thermal Effects of an Expanding Power Industry: Ohio River Basin I, BNWL-1299' have been published and are available from the Clearinghouse for Federal Scientific and Technical Information. A complete assessment of the cooling capacity of the entire Mississippi River system is presently underway. Surveys of the cooling capacity of Atlantic and Gulf coast systems are planned.

SUPPORTED BY U.S. Atomic Energy Commission

2.1761, FISH BEHAVIOR AND PHYSIOLOGY
A.B. GROVES, U.S. Dept. of Commerce, Natl. Marine Fisheries Service, *Seattle, Washington* 98102

The essential purpose of this work is to acquire a knowledge of intrinsic physical and sensory abilities of fish which relate to specific environmental factors encountered in migration and fish passage situations. A broader purpose is to assess the adaptive ranges of these capacities in different migratory fish stocks. This information will be applied to help predict or anticipate the effects on migrant fish of various river and estuarine development programs which are creating numerous changes in the environments of native stocks of commercially valuable species.

Specifically the work is with salmonids and involves measurements of fish capacities against selected environmental variables. This includes measurements of swimming performance abilities of juvenile and adult fish and activity patterns and responses of salmonid species. Studies also are made of sensory responses which may relate to migration and homing behavior, of physical and hydraulic factors that can injure fish in power turbines, of responses that may aid in diverting fish away from dangerous areas in turbines, and of effects on migrants of thermal shock such as that encountered by passing through heated effluents from thermal power plants.

The work is now in the laboratory but is directed to the idea that the derived information can be applied directly to field problems.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1762, COASTAL AND ESTUARINE RESOURCE DEVELOPMENT
T. JOYNER, U.S. Dept. of Commerce, Natl. Marine Fisheries Service, *Seattle, Washington* 98102

Waters of estuaries and bays of Puget Sound offer attractive sites for water-cooled thermal-electric plants. Several large plants (1000 plus MGW) are already under consideration and more will undoubtedly follow in the near future. Uncontrolled discharge of effluents from these plants could produce environmental changes unfavorable to certain marine species. In contrast, when properly controlled and directed to produce changes calculated to optimize production and growth of desired marine organisms, effluents may be regarded as beneficial additives for aquacultural systems.

The purpose of these studies will be to: (1) Determine response and tolerance to thermal change of commercially significant marine organisms and their food sources. (2) Assess potentials for use of heated effluents for aquacultural systems.

A mobile field laboratory will be used to carry out on-site thermal tolerance experiments with organisms native to the area. Closed-system designs using thermal effluents for culture of oysters, clams, crustaceans, and other commercially important marine organisms will be explored.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1763, EFFECTS OF INDUSTRIAL EXPANSION ON THE AQUATIC ENVIRONMENT OF ESTUARINE AREAS
G.R. SNYDER, U.S. Dept. of Commerce, Natl. Marine Fisheries Service, *Seattle, Washington* 98102

The Lower Columbia River and its estuary plays a critical role in the life cycle of anadromous salmonids. Each year millions of young fish move downstream from native rearing areas and artificial propagation facilities. These fish all pass through the lower river and estuary where they undergo physiological transformations in preparation for their movement from fresh to salt water. The estuary also is an important nursery area and the transition zone for marine species of fish.

Industrial expansion in this area by the thermal electric power, aluminum, and pulp and paper industries can drastically modify the environment. Forecasts indicate that over 2000 MW. of electricity (possibly 4000MW.) could be produced in the Columbia estuary by 1985. The effects of waste heat discharged from these plants could be detrimental to the overall aquatic ecology and specifically to the production of commercial species of fish. Limnological studies are planned to determine the existing ecology at sites known to have potential for industrial expansion. The effects of increases in water temperature on aquatic organisms at specific sites will be studied. Predictions of physical and biological changes will be made. The effects of the environmental changes on fish and on secondary organisms necessary for their survival and growth will receive initial emphasis.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1764, EFFECT OF ENVIRONMENTAL POLLUTION ON FISH DISEASES - EFFECT OF HEAT STRESS ON DISEASE RESISTANCE MECHANISMS IN SALMONID FISHES
G. WEDEMEYER, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Seattle, Washington* 98115

Anadromous fishes may be forced to swim through areas of thermal pollution during their fluvial migration. The effect of such heat stress on the host-defense mechanisms against infectious diseases will be studied using the juvenile coho salmon and steelhead trout.

Fish acclimated to 50F will be subjected to selected heat-stress regimens and changes in those physiological parameters involved in non- immunological disease resistance will be measured. These will include inter-renal vitamin C, the 17-hydroxycorticosteroid hormones, plasma proteins, glucose, oxygen levels, and blood buffering capacity.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1765, COLUMBIA RIVER EFFECTS IN THE NORTHEAST PACIFIC - A) BIOLOGICAL; B) CHEMICAL AND GEOLOGICAL; AND C) PHYSICAL OCEANOGRAPHY
C.A. BARNES, Univ. of Washington, School of Arts, *Seattle, Washington* 98105 (AT(45-1))

The planned research extends that initiated in 1961 and directed towards determining the properties, distributions and movement of Columbia river water and its transported load including radionuclides in the Northeast Pacific, and establishing a base for predicting the general behavior of river water at sea. Past measurements have provided a general description of water mass properties, currents, nutrients, dissolved oxygen, selected radionuclides, phytoplankton, primary productivity, selected zooplankton and benthos, bathymetry, sub-bottom structure, and characteristics of sediments in the river and on the adjacent sea floor. The continued studies are subdivided into three separate subproject and subject areas: A) Biological, B) Chemical and Geological, and C) Physical Oceanography, and will investigate in greater depth selected properties and processes as follows: A) Phytoplankton including the subsurface chlorophyll maximum layer, excretion of organic matter, annual production and theoretical model studies of production; distributions of zooplankton and biomass, zooplankton-phytoplankton relationships, oxygen consumption in the seabed, DNA in marine sediment, benthic communities and taxonomy of polychaetes; B) Determination of mercury concentrations in waters and sediments of the Columbia River and adjacent marine environment, associated processes and rates of interchange; identification and budgets of Columbia River sedimentary and contributing dissolved materials in the deep waters and bottom sediment over the continental shelf, slope and border land; and construction of a computer model pertinent to effluent movement and sediment distribution; C) Direct measurement of currents and winds with buoyed arrays at fixed locations off the Washington coast stressing the basic dynamics; theoretical study of the three-dimensional circulation near the river mouth; numerical modelling of the coastal area from 42 degrees to 48 degrees N; completion of bottom drifter studies and hydrographic atlas.

2.1766, WATER RESOURCES SCIENTIFIC INFORMATION CENTER, WATER QUALITY REQUIREMENTS AND EFFECT OF WATER POLLUTION ON FRESHWATER MARINE ORGANISMS
M. KATZ, Univ. of Washington, School of Fisheries, *Seattle, Washington* 98105

The establishment of a Water Resources Scientific Information Center to collect and abstract the current pertinent world literature on the water quality requirements of freshwater and marine organisms is proposed. It is further proposed to collect and abstract the world literature on the effects of water pollution on freshwater and marine organisms.

The Principal Investigator has the resources of the Fisheries--Oceanography as well as the other libraries of the University of Washington, besides an extensive personal exchange with leading water quality workers of the world. It is expected that over 500 titles will be collected and abstracted during the first year of the project.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1767, PHYSIOLOGY AND ECOLOGY OF MARINE DIATOMS
J. LEWIN, Univ. of Washington, School of Arts, *Seattle, Washington* 98105

Funds from this grant continue NSF support of investigations concerned with the physiology, nutrition and systematics of marine diatoms. Specifically the projects are (1) comparative morphology and physiology of species belonging to the genus Chaetoceros, especially with regard to morphological structure of

the silica shell and setae as revealed by electron microscopy; and of salinity tolerances as revealed by laboratory cultures; (2) field and laboratory investigations of surfzone diatoms of the Olympic Peninsula with respect to their responses to nutrients and their growth responses to various nutrient concentrations; (3) studies of heterotrophic nutrition of marine pennate diatoms as related to growth promoting substrates; (4) exploratory studies to determine the nature of available and unavailable iron in sea water from various localities; (5) isolation and culture of certain species of algae from the deep phytoplankton layer which exists below the 1 percent light level and which makes a considerable contribution to primary production; and (6) investigations of the response to boron of various species of centric diatoms particularly to test the possible role of boron in cell metabolism. Marine diatoms in temperate neritic ocean waters are the major plant contributors to primary production. These investigations provide information which will be useful in considering the effects of organic, inorganic and thermal pollutants on the behavior of various species of marine organisms.

2.1768, THE RESPONSE OF LAKE SAMMAMISH LIMNOPLANKTON TO SEWAGE WASTE DIVERSION

E.B. WELCH, Univ. of Washington, School of Engineering, *Seattle, Washington* 98105

A study to determane the recovery characteristics of eutrophic Lake Sammamish following sewage waste diversion is proposed. Changes in primary and secondary productivity nutrient budgets and physical characteristics will be monitored for a two year period to establish rate and trends of recovery. Responses of limnoplankton productivity, as well as chemical and physical factors, in Lake Sammamish will be compared with similar responses occurring in Lake Washington following sewage diversion. These comparisons will be made statistically so that significant results can be used to develop prediction models for lake productivity responses to sewage diversion. In addition, particular attention will be given to the effects of yellow organic acids on algal productivity since Lake Sammamish apparently receives yellow organic acids from bogs and lakes located to the east. The complete findings of this study should provide tentative means for estimating the response of lakes physically similar to Sammamish to diversions of sewage carrying large quantities of algal nutrients.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1769, INFLUENCE OF INDUSTRIAL AND MUNICIPAL WASTES ON ESTUARINE AND OFF SHORE WATER QUALITY

J.F. SANTOS, U.S. Dept. of the Interior, Geological Survey, *Tacoma, Washington* 98402

This project is being carried on in cooperation with the Municipality of Metropolitan Seattle.

A major objective is to study the influence of industrial and municipal waste disposal on all phases of water quality, chemical, physical, ecological, and sanitary in fresh, brackish, and saline environments. Measurements made with multiple parameter water quality recorders at four sites on the Duamish River estuary are the basis for the attempted correlations. Parameters recorded include dissolved oxygen, specific conductance, water temperature, pH, turbidity and solar radiation index. Computer programs will be written to analyze these data and to detect significant relations.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.1770, IMPACT OF CORPS OF ENGINEERS CONSTRUCTION ACTIVITIES ON THE ECOLOGICAL ENVIRONMENT

H. MILLS, Marshall University, School of Arts, *Huntington, West Virginia* 25701 (DACA)

Technical Objective: The objective of this work unit is to provide consultant services and to define areas and capabilities for environmental research as related to the U. S. Army Engineer Waterways Experiment Station in particular and the U. S. Army Corps of Engineers in general, with emphasis on the extreme importance of developing an in- house capability for a coordinated systems approach to meet military as well as civic needs. Army interests in ecology include but are not limited to the conduct of military and construction activities so that the ecological environment will not be adversely affected. Military reservations together with theaters of operations encompass all aspects of ecology such as water resources, land and forests which together contain all species of fish and wildlife.

SUPPORTED BY U.S. Dept. of Defense - Army

2.1771, GROWTH OF THE BROWN BULLHEAD, ICTALURUS NEBULOSUS (LE SUEUR), IN MINE ACID POLLUTED WATER

A. BENSON, West Va. University, Water Research Institute, *Morgantown, West Virginia* 26506

The study is an evaluation of the environmental effects of acid mine water on growth rates of the brown bullhead, Ictalurus nebulosus (Le Sueur). The investigation is based on evident tolerance of this species to acid conditions and its possible management potential in acid water.

The procedural research plan includes: (1) comparative sampling of brown bullhead populations in acid and non-acid bodies of water; (2) collecting data on environmental conditions; (3) determining growth rates; and (4) collecting supplemental data on food habits and on food availability.

The results are expected to be useful in management planning for sport fisheries, in establishing water-quality criteria, and in planning future research.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1772, MICRO-ECOSYSTEMS SIMULATION OF PRIMARY PRODUCTION IN THERMAL AND ACID MINE WATER LOADINGS RELATED TO WATER USE OF THE MONONGAHELA RIVER

E.C. KELLER, West Va. University, Water Research Institute, *Morgantown, West Virginia* 26506

This project is concerned with the empirical systems simulation of sets of micro-ecosystems in regard to the joint, interacting effects of thermal loading and variable levels of acid mine water. Following the systems analysis of the empirical stimulation results, preliminary mathematical modeling will be developed for predictive purposes. Some field work will evaluate the modeling attempts.

The general approach of the project will consist of three distinct phases: 1. Examination by sampling of the phytoplankton of natural waters of selected segments of the Monongahela River, including two thermal outfalls. 2. Laboratory controlled experiments concerning specific conditions in simulated microecosystems and construction of empirical models (or model) consistent with the findings of No. 1. 3. Construction of mathematical models in a systems context from the empirical data and models from Nos. 1 and 2 above.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1773, PHYSIOLOGICAL EFFECTS OF SUBLETHAL LEVELS OF ACID WATER ON FISH

W.J. PEGG, West Va. University, Water Research Institute, *Morgantown, West Virginia* 26506

The project proposes to determine metabolic rates by indirect calorimetric methods; eg, measurement of oxygen consumption of sunfish and bullheads which have been subjected to different laboratory controlled aquatic environments. The environment will consist of acid waters with pH ranges about 6.0 to 3.0 and cold total acidities varying from 3 to 70 mg/l $CaCO_3$. The environmental waters will be composed of combinations of acid coal mine drainage water and solutions of sulfuric acid diluted with natural river water and constituted river water. Calcium levels are to be varied in the test waters to determine whether or not increased levels of environmental calcium can reduce the effect of acid water. If oxygen consumption is a valid measure of energy utilization in fish, then increased metabolic rate under acid water conditions would indicate that the fish must expend energy to compensate for the stress induced by the environment.

2. WATER QUALITY

This research proposes to add metabolic rate data relative to the acid environment typically found in the Monongahela River basin. It also proposes to evaluate the relative tolerances of native river fish to the acid environment. The study may also be considered as an effort to gain more appropriate water quality criteria applicable to the problems of reclamation and maintenance of a sport fishery in the Monongahela River basin.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1774, EVALUATE PERFORMANCE OF POULTRY AS AFFECTED BY WATER QUALITY
R.A. PETERSON, West Va. University, Agricultural Experiment Sta., *Morgantown, West Virginia* 26506 (WVA00148)

OBJECTIVE: To determine and evaluate the effect of various water quality factors on biological performance of poultry as they exist in West Virginia.

APPROACH: Field trials will be conducted to determine water quality conditions and their effect upon biological performance, both before and after treatment in broilers and laying hens.

PROGRESS: Two field studies are being conducted to determine the effects of water treatment in (1) a 10,000 cage-layer operation and (2) a 52,000 capacity broiler operation. Caged hens are receiving well water that is untreated, superchlorinated, dechlorinated and dechlorinated-demineralized. The broiler study treatments are as such: pond water that is untreated, superchlorinated, filtered super- chlorinated and filtered dechlorinated. Productive performance data, being collected monthly and by the brood, as yet has not been analyzed as the tests will not be completed for another year. Water Quality Study. Work done at the Kite Farm, a poultry layer operation, has principally been concerned with the collection of temperature data both inside and out, and the treatment of water and its measurement for layers in cages. The effects of water treatment and temperatures on egg quality and production at this point are inconclusive. Difficulty with equipment to accurately measure water consumption has been experienced and work is continuing to improve water measuring methods and equipment. Water treating equipment is working satisfactorily. The water treatment and measuring equipment installed at the Funkhouser broiler houses near Moorefield is working well but again at this time results of this study are not conclusive.

SUPPORTED BY West Virginia State Government

2.1775, INFLUENCE OF ACID MINE WATER UPON ACID TOLERANCE AND SYNTHETIC ABILITY OF SEWAGE MICROORGANISMS
H.A. WILSON, West Va. University, Water Research Institute, *Morgantown, West Virginia* 26506

The research proposes to study differences between acid-tolerant and acid-intolerant bacteria isolated from polluted streams containing sewage and acid mine water, and to determine whether the environment created by the acid mine water interferes with the synthetic ability of certain bacteria, thereby causing them to be acid intolerant. Particular regard is to be given RNA, DNA, and amino-acid cell leakage. Radioisotopes of Na, K, and H are to be used to study cell leakage and internal pH. Results of the research may aid in water-quality management or treatment-plant and treatment-procedures design. Standard microbiological and analytic-chemical procedures and gas chromatographic, liquid-scintillation, and amino-acid-analyzer methods will be used. Minimum-growth pH will be determined for acid-tolerant and acid-intolerant isolates.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1776, MICROBIOLOGY OF FARM PONDS
H.A. WILSON, West Va. University, Agricultural Experiment Sta., *Morgantown, West Virginia* 26506 (WVA00132)

OBJECTIVE: Study qualitatively and quantitatively, the microbiological population of fresh water systems and the factors influencing this population; whether certain special bacterial groups such as cellulose decomposers, nitrifiers, nitrogen fixers, etc., are present: the effect that pesticide and herbicide residues have upon the microbial population of such waters and whether any members of the water microflora are capable of degrading either the active or inert constituents of such materials; the potential danger to livestock drinking from ponds and stagnant pools when heavy algal growths appear; the probable pollution hazards to ponds and streams from garbage dumps, sanitary landfills and domestic sewage from private residences.

APPROACH: Standard microbiological procedures will be the general basis of study.

PROGRESS: Coliform and enterococci densities were greater in ponds receiving run-off water from livestock areas. No psychrophilic bacteria, optimum growth below 20 C, were found although some isolates grew slowly at temperatures near O C. The relative stability of the farm pond waters studied was about 99% as determined by the methylene blue test. This was substantiated by the biochemical oxygen demand (BOD), which ranged from 1.1 to 315 mg oxygen consumed per liter. Rivers with BOD values between 1 and 4 ppm have been considered clean. Sediment BOD values ranged from 20 to 45 ppm per gram on an oven dry basis. This indicates the considerable amount of organic matter in pond sediment. The bacterial flora of ponds apparently is predominantly small gram negative rods with gram positive rods and cocci in considerable lesser numbers. This corresponds to findings of fresh water lakes. Microscopic examination of slides submerged in pond water revealed considerable numbers of algae as well as bacteria. Most of the algae were diatoms belonging to the genera Fragilaria, Diatoma, Synedra, Surirella, Stauroneis, and Navicula.

2.1777, IMPACT OF LAGOONS AND SAND BLANKETS ON FISH, AQUATIC LIFE AND WATER EQUALITY
D.A. BRATLEY, State Dept. of Nat. Resources, *Delafield, Wisconsin* 53018

Phase one, involved assembling Public Service Commission records on characteristics and extensiveness of lagoons and sand blankets in inland Wisconsin lands. Phase two, involved field research on Lake Winnebago and southeastern Wisconsin lakes to determine the effects of encroachments upon species composition, density, and dominance of aquatic vegetation, fish, bottom organisms and plankton. Water Quality Stations were also monitored in connection with this work. A completion report is being prepared.

SUPPORTED BY Wisconsin State Government - Madison

2.1778, EFFECTS OF DREDGING ON THE ECOLOGY OF SPRING PONDS
R.F. CARLINE, State Dept. of Nat. Resources, *Madison, Wisconsin* 53701

Objectives: Determine the effect of dredging on the important physical, chemical and biological characteristics of spring ponds, with particular reference to trout populations and the sport fishery.

Procedure: Determine: (1) the standing crops, growth and survival of trout populations in spring ponds, (2) growth rate and age structure of trout populations in outlet streams of spring ponds,(3) timing and magnitude of movement of trout between spring ponds and their outlet streams, (4) extent, location, timing, of spawning by trout in spring ponds and the hatching success of eggs spawned, (5) yield of trout from spring ponds,(6) food habits of trout in spring ponds,(7) standing crops and generic composition of the benthic invertebrate and planktonic populations in spring ponds, (8) important limnological characteristics of spring ponds, (9) hydrologic characteristics of spring ponds, and (10) cost effectiveness of spring dredging.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1779, BIOLOGICAL NITROGEN FIXATION IN LAKES, PHASE II
R.H. BURRIS, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

A mobile laboratory has been equipped for routine analytical work including gas chromatography. This laboratory will be used

to study biological N2 fixation in lakes and on the fringes of lakes. Samples of aquatic flora and of root nodules of higher plants will be exposed in the field to acetylene under a close approximation of natural conditions. Reduction of acetylene to ethylene will be determined by gas chromatography and will be used as an index of the activity of the N2-fixing system. The data will be evaluated in terms of the role of biological N2-fixing agents, particularly the blue-green algae, in eutrophication of fresh water lakes.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1780, ECOLOGICAL RESPONSES OF FISHES AND FISH-FOOD ORGANISMS TO HEATED EFFLUENT - CASE STUDY OF LAKE MONONA, WISCONSIN
J.J. MAGNUSON, Univ. of Wisconsin, Graduate School, *Madison, Wisconsin*

The major objective of the research program is to evaluate the effects of steam-electric plant operation on the ecology of lake fishes and their food organisms. In the present project, certain ecological responses of fishes and invertebrates living in the littoral zone of Lake Monona will be assessed with respect to uptake, heating, and discharge of condenser-cooling water from Madison Gas & Electric Co.

Field investigation will consist of the following phases: 1. Diurnal and seasonal distribution patterns of fishes in relation to littoral temperature gradients produced by cooling-water discharge. 2. Growth rates of young fishes in the outfall area as compared to other littoral areas. 3. Food habits of bluegills and longnose gar in outfall and other littoral areas. 4. Movements of fishes within the outfall area and among outfall and extra-outfall areas. 5. Distribution and abundance of invertebrate fish-food organisms in the outfall area as compared to other littoral areas. 6. Uptake and discharge of fish-food organisms in the condenser-cooling water.

The following laboratory investigations will be conducted to complement the field research: 1. Temperature selection by representative fish- and invertebrate-eating fishes of Lake Monona in the absence of other major variables. 2. Effects of food distribution and predators on temperature selection in fishes. 3. Effects of differences in temperature acclimation of predator and prey fishes on predation.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1781, THE AQUATIC ENVIRONMENT AND ELECTRICAL POWER GENERATION
R.A. RAGOTZKIE, Univ. of Wisconsin, School of Letters, *Madison, Wisconsin* 53706

The environmental effects of electrical power generation, using the Great Lakes for cooling purposes, will be studied along with socio economic considerations.

The first project includes the alteration of the physical environment by the discharge of heated effluence and the prediction of plume behavior. The behavior of migrating coho salmon, as modified by these discharges, is under investigation along with the influence of the heated discharge on the already stressed Alewife.

Future projects will include studies of (1) radioactive uptake by organisms gathered in the heated discharges, (2) contrast of the potential detrimental effects of fossil vs. nuclear power, (3) an analysis of the uses of electricity which could be considered essential, unessential or wasteful, and (4) a study of the human perception of pollution caused by nuclear generation of the Great Lakes.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1782, PHYSIOLOGICAL RESPONSES TO THERMAL POLLUTION
A.H. HOUSTON, Marquette University, Graduate School, *Milwaukee, Wisconsin* 53233

An attempt will be made to assess the physiological status of animals maintained under conditions of thermal pollution in terms of the systemic responses invoked to meet basic vegetative requirements, and the secondary effects which such adaptations may induce. For purposes of the present study emphasis will be placed upon cardiovascular- respiratory adjustment associated with the satisfaction of temperature- elevated oxygen demand in a desirable game fish species, the brook trout, and a frequently potential competitor, the common carp. Experimentally, the study will involve determinations of routine levels of oxygen consumption, cardiac and ventilation rates, and the oxygen tensions of inspired and expired water, and arterial and venous blood. The effects of cardiovascular respiratory adaptation upon water- - electrolyte regulation, a critical factor in systemic and metabolic control, will be evaluated through determination of blood and tissue levels of the major electrolytes and water, phase distribution analysis, and estimations of cellular ionic composition. In conjunction with this renal responses will be investigated through determinations of glomerular filtration rates, urine flows, urinary water-electrolyte levels and tubular recovery rates of th elements considered.

SUPPORTED BY U.S. National Science Foundation

2.1783, PHYSIOLOGICAL AND BIOCHEMICAL TECHNIQUES TO ASSESS THE EFFECTS OF SUBLETHAL CONCENTRATIONS OF CHEMICAL WATER POLLUTION ON FISH
H.M. MILES, Marquette University, Graduate School, *Milwaukee, Wisconsin* 53233

The ultimate objective is to develop techniques that will yield new information on the effects of heavy metal pollutants on the metabolism and physiology of fishes.

The rate of uptake of mercury from water by fish and its distribution in the various tissues will be determined by radiotracer studies. Physiological parameters in wild populations of fish living in mercury contaminated areas will be compared to those living in control areas.

The effects of mercury on the kidney function of adult fish will be determined along with a general sublethal bioassay method.

Observation of physiological parameters will be expanded to include fish exposed to other heavy metals.

SUPPORTED BY Wisconsin State Government - Madison

2.1784, PHYSIOLOGICAL EFFECTS OF THERMAL POLLUTION ON TROUT
E.M LONSDALE, Univ. of Wyoming, School of Engineering, *Laramie, Wyoming* 82070

Efforts are being made to remotely monitor physiological data from fish and wildlife with the main interest being the telemetry of EKG potentials from free swimming trout. Heart action of fish is very sensitive to water temperature.

SUPPORTED BY University of Wyoming

G. SOCIETAL IMPLICATIONS, MANAGEMENT, AND OTHER ASPECTS OF WATER POLLUTION

Legislation, Administration, Standards, Socio-economic Studies, Government Relations, Planning, Protection and Miscellaneous Environmental Pollution Studies.

2.1785, GEOLOGIC AND HYDROLOGIC STUDIES RELATED TO SPECIFIC POLLUTION PROBLEMS
R.M. ALVERSON, State Geol. Survey, *University, Alabama* 35486

The purpose of the project is to conduct geologic and hydraulic studies, research, and investigations in connection with specific ground and surface water pollution problems under consideration by the supporting agency. A report is in preparation documenting the growth of such activities through the years, relating specific pollution problems to geology and hydrology, and making recommendations as to areas and fields into which this cooperative approach to specific pollution problems can be expanded.

2. WATER QUALITY

SUPPORTED BY Alabama State Government

2.1786, WATER RESERVOIR SYSTEMS
J.J. KALVINSKAS, North Amer. Rockwell Corp., *Anaheim, California* 92803 (C-1187)

A program is proposed to investigate a reservoir system network in an urban area to alleviate problems of storm water runoff, eliminate costly and cumbersome sewer networks for storm drainage, and simultaneously provide for rainfall conservation. The study would be accomplished by conducting a systematic analysis of water runoff in an urban area, evaluating the location of a multiplicity of reservoirs throughout the area, and investigating both surface and subterranean reservoirs for rainfall storage.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1787, A SYSTEM APPROACH FOR INTEGRATING GROUNDWATER AND SURFACE-WATER USE
R.E. MITCHELL, Aerojet General Corporation, *Azusa, California* 91702 (C-1136)

This program will produce an analytical technique by which the most efficient utilization of water resources may be determined. The influence factors of potential surface supplies, quantity and quality needs of the users, waste-water treatment, groundwater pollution, community growth characteristics, economics, and legal/organizational needs will be included.

This research program is undertaken to present a systems approach to the preservation of the quality and quantity of the groundwater resource.

The research program will evaluate the projected needs of a typical expanding urban/rural community currently using groundwater supply and evaluate the steps to be taken to best provide the future water supply. The various sources of surface water and groundwater and their quality management will be considered. In addition, all the system constraints will be included so that a useful approach will be defined. To validate the approach, the study will be related to an existing groundwater problem area. The program will relate all the factors, both direct and indirect, to provide a master plan for this area.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1788, MANAGEMENT GUIDES UNDER ACCELERATED RECREATION DEMANDS AND INTENSIVE LAND USE
R.H. TWISS, U.S. Dept. of Agriculture, Pac. Sw. For. & Rg. Expt. Sta., *Berkeley, California* (PSW1901)

OBJECTIVE: Clarify and study the problems of planning and managing forest lands where there are accelerating land-use pressures and intensive recreation demands.

APPROACH: Study will be made of the principles of analyzing scenic aspects of resources, campground ecology, trends in the use of campgrounds and other intensively used sites, what forest recreation visitors seek and how they are affected by crowding or land management changes, improvement in plantings and horticultural treatments on forest recreation areas and integration of forest recreation with general resource or economic development. (3 to 7 my.)

PROGRESS: A comprehensive study of a 36 square mile watershed in urbanizing Marin Co. in California was completed. It considered major environmental factors which might affect future development, including geologic hazards, vegetation, soil, wildlife resources and climate, especially as it relates to problems of air pollution and also visual impact of future development. The study documents the critical need for locally based decisions on resource alterations, resource management, and design control. This approach should be a basic step in land management, as a guide to regional environmental quality planning, project review, and plan formulation. The techniques developed are being extended to other areas having similar development problems. Changes in conditions that may have been caused by recreational use, from 1961-1966, at five campgrounds were studied. The increase in vegetation after 5 years was attributed to barriers placed in campgrounds and to greater precipitation. The over-all improvement in campground conditions is interpreted as an 'adjustment' to recreational use. Ski resort simulation model was field tested on several proposed developments. The resultant predictions added objective support to actual planning decisions made by NFS. Original model has been improved through additional data collection during the past winter sports season.

SUPPORTED BY U.S. Dept. of Agriculture

2.1789, EVALUATION OF GROUNDWATER RESOURCES, LIVERMORE VALLEY, CALIFORNIA
P.A. WITHERSPOON, Univ. of California, School of Engineering, *Berkeley, California* 94720

A predicted rapid increase in the population of Livermore Valley, California over the next few decades points to the need for a master plan of water management. The main objective of this investigation is to provide quantitative data on the hydrologic characteristics of the groundwater basin of this valley that can be used in formulating this plan. An improved mathematical model has recently been developed at the University of California and will be the principal analytical tool.

A three year program of investigation is proposed. The first year will be spent in collecting basic hydrologic data. The geology has recently been worked out by the California Department of Water Resources. The second year will be spent in setting up two-dimensional and three-dimensional models of the basin. With this approach, it will be possible to investigate: (1) subsurface rates and directions of flow, (2) effectiveness of existing hydrologic barriers (vertical and horizontal), and (3) effect on subsurface flow patterns of current and future rates of recharge and discharge. The third year will be devoted to an analysis of the probable impact on subsurface hydrologic conditions over the basin of anticipated rates of water withdrawal and waste water disposal.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1790, ENVIRONMENTAL DECISION-MAKING IN THE LAKE TAHOE BASIN
L.D. MUSOLF, Univ. of California, Graduate School, *Davis, California* 95616

Lake Tahoe, the largest alpine lake in North America, is situated at an altitude of 6,200 feet in a 500-square mile basin astride the California-Nevada border. The combined effect of lake, shores, streams, and surrounding mountains is one of the outstanding natural and scenic resources of the world. For the very reason that the Tahoe Basin is so attractive, its unique qualities are threatened by the activities of man. Development of the area to date has been controlled largely by market demand. Problems of urbanization are developing, the most notable of which is the increasing eutrophication of the lake.

A newly formed group of faculty members representing a variety of separate disciplines, including the social sciences, humanities, law, engineering, and ecology will undertake the development of an interdisciplinary approach to long term research on the interrelationships of human decision making and environmental conditions in the Tahoe Basin. The use of the findings of such research will be utilized in the development of a predictive model which can anticipate the environmental consequences of different decision strategies. It is hoped that the model may be used as a tool in assisting public agencies to plan their future actions in the Tahoe Basin. The initial stages will be concerned with the development of a systems model concerned with environmental decision making.

SUPPORTED BY U.S. National Science Foundation

2.1791, THE ECONOMICS OF WATER TRANSFER - AN APPRAISAL OF INSTITUTIONS
J.H. SNYDER, Univ. of California, Agricultural Experiment Sta., *Davis, California* 95616 (CA-D-AEC-2210-RR)

OBJECTIVE: Collect, assemble and analyze primary and secondary data relating to vegetable crop production and water use and nonagricultural water use. Analytical techniques include linear programming, variate difference analysis, and Markov chain techniques. Evaluation of institutional arrangements influencing water use and water use transfer. Case study of such in-

stitutions as the Monterey County Flood Control and Water Conservation District will be supplemented by regional input-output analysis and may involve some river systems analysis.

PROGRESS: The total environment of the water economy of the Salinas Valley, including the institutional framework of a flood control and water conservancy district provided the focal point for analyzing water development, use, and transfer problems of the area. This study inquired directly into operationally feasible adjustments that could be implemented within the existing political and institutional environment. It emphasized the evaluation of political-institutional structures, legal structures, and administrative techniques. Optimal water management rationale for the water district was defined within the composite structure of the water economy. Analysis indicates that inefficiency costs associated with an absence of direct control of water withdrawal may or may not be large relative to those under a control scheme. It is concluded that economic incentives for aggregate water use are not vastly different with or without pumping controls when relatively low-cost, supplementary water supplies are available. Availability of such supplies places the principal emphasis on equity rather than efficiency factors. Further analysis of the salt-water intrusion problems found that the threat of court action by the injured parties caused a shift from the present status quo solution to one where pumpers in the uncontaminated area would be as well off if they contributed to the cost of a fresh water canal rather than suffer the consequences of having the courts adjudicate the basin. The aggregate profit level of the entire pressure area would be maximized under this solution as well.

SUPPORTED BY U.S. Dept. of Agriculture

2.1792, AN INVESTIGATION INTO RECREATIONAL WATER QUALITY CRITERIA
L.A. SCHINAZI, Aerojet General Corporation, *El Monte, California* 91734

This study has as its primary objective the establishment of a scientific basis from which meaningful recreational water quality criteria can be formulated. Ultimately, such criteria would be used as guidelines for setting recreational water quality standards. The health hazards faced by aquatic recreationists during primary contact activities (swimming, skindiving, etc.) in polluted water are being reviewed, analyzed, and mathematically related, with a view toward the construction of mathematical models which will correlate the variables involved in this epidemiological situation.

A secondary objective is the delineation of information gaps in our knowledge with respect to certain parameters needed to develop a rational basis for criteria formulation, and to suggest areas of needed research. The present investigation is restricted to a consideration of nine factors that represent the types of problems and parameters of importance in the development of recreational water quality criteria, namely, (1) total coliforms; (2) fecal coliforms, (3) salmonella, (4) viruses. (5) pesticides, (6) oils, (7) temperature, (8) pH, and (9) clarity.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1793, MEASUREMENT AND MANAGEMENT ASPECTS OF WATER TOXICOLOGY
E.S. FLOWERS, Univ. of California, School of Public Health, *Los Angeles, California* 90024

In this project, it is proposed to train students in laboratory skills and technical considerations necessary to evaluate, review, define, and manage water quality problems. Both laboratory and field studies will be conducted in four areas of interest. These are biomagnification of water contaminants in the food web, the effects of thermal additions to water on aquatic biota, airborne contamination of watersheds, and threshold effects of stressor agents. Contaminants to be considered include heavy metals, pesticides, radionuclides, and temperature changes.

Laboratory studies will involve analytical chemistry of contaminants and aquarium or light box studies of environmental factors affecting the numbers diversity, reproductive capacity, or behavior of aquatic species. Field studies using a material balance approach will be conducted on residential and wilderness areas of the Malibu Creek watershed in the Los Angeles area.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1794, SUPPORT OF RESEARCH VESSEL OPERATIONS
J.M. SAVAGE, Univ. of Southern California, Graduate School, *Los Angeles, California* 90007

This grant provides funds for the operational expenses of the research vessel VELERO IV of the University of Southern California. During the grant year the vessel supports an intensive program of study on the physical, geological and biological characteristics of the ocean off shore of central and southern California with special emphasis on the Santa Barbara Island basins. Specifically these investigations include studies of the relationship between the characteristics of water mass and the distribution and ecology of the midwater animals of the area; a study of bacterial populations in the areas where wastes are discharged into coastal waters; a study leading to the development of a system using the light absorption characteristics of coastal waters to define areas of pollution; studies on the biological effects of the oil spillage in the Santa Barbara channel; as well as a study of potential economic mineral concentrations on the coastal shelf off Southern California.

SUPPORTED BY U.S. National Science Foundation

2.1795, MARKETS TO 1980 FOR WASTE WATER TREATMENT AND RENOVATION FACILITIES
R.E. DELARUE, Stanford Research Institute, *Menlo Park, California* 94025

The overall objectives of the study are (1) to identify markets whose growth will offer business opportunities to suppliers of equipment, chemicals, materials, and services for waste water treatment; (2) to establish a timetable for the growth rates of these markets; and (3) to identify business strategies through which companies can successfully penetrate the markets. Specifically, the objectives are to:

1. Forecast the markets of 1980 for both municipal and industrial waste water treatment facilities that will be required for treatment of waste water either for release or reuse; including cooling towers.

2. Forecast the markets to 1980 for equipment (including instrumentation) and services for both municipal and industrial facilities.

3. Forecast the markets to 1980 for chemicals, materials, and supplies that will be consumed in the operation of municipal and industrial facilities.

4. Evaluate the effects of anticipated government legislation, policies, and expenditures on the markets for waste treatment and renovation.

5. Identify and analyze the criteria necessary for sponsors to compete successfully and profitably for these markets.

SUPPORTED BY No Formal Support Reported

2.1796, ASSESSMENT OF THE MARKET FOR WATER AND WASTE WATER INSTRUMENTATION AND CONTROLS, AND WATER QUALITY MONITORING SYSTEMS
R. MIKULA, Stanford Research Institute, *Menlo Park, California* 94025

The objectives of the research are to: (1) Forecast the market for instrumentation and controls in water treatment applications, (2) Forecast the market for water quality monitoring systems used by government agencies, (3) Assess the expected change in technology, user requirements, and competitive environment in these markets, (4) identify and evaluate the factors and business strategies that allow a company to compete profitably and successfully for these markets. Project initiated in 1968 and is continuing.

2. WATER QUALITY

SUPPORTED BY No Formal Support Reported

2.1797, PALO ALTO, SAN MATEO, AND MONTARA MOUNTAIN 7.5-MIN. QUADRANGLES AND VICINITY, CALIFORNIA
E.H. PAMPEYAN, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

States to which project pertains: California.

Objectives of the project are: (1) To prepare detailed geologic maps of bedrock and surficial deposits of the Palo Alto, San Mateo, and Montara Mountain Quadrangles, and adjacent parts of the Redwood Point and Woodside quadrangles that will establish the geologic framework and supply basic engineering geologic data needed by planners, engineers, and contractors for proper development of urban expansion and engineering structures in this area. (2) To add to the scientific knowledge of the geologic features. (3) To study the earth materials, including their physical properties and engineering behavior relative to foundation stability and use as construction materials.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.1798, FORMULATION OF A GENERAL MATHEMATICAL MODEL FOR THE PREDICTION OF THERMAL ENERGY CHANGES IN IMPOUNDMENTS
G.T. ORLOB, Water Resources Engineers Inc., *Walnut Creek, California* 94529

The development of a generalized mathematical model which will represent, within the practical and reasonable limits of accuracy, the thermal changes which may be expected under alternative hydrologic, hydraulic, and climatologic conditions for operating reservoirs. It is intended that the work support and complement that already completed or underway by the Study Team in its investigation of the Columbia River System.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1799, NATIONAL AND ENVIRONMENTAL HAZARDS, DISORDERS, ENVIRONMENTAL QUALITY
I. BURTON, Univ. of Toronto, *Toronto, Ontario, Canada*

Several projects on various agents of human response to environment, forestry, and environmental quality and stressful elements in the environment studies on the following topics: Snow hazard in urban areas. Perception of hazards. The hazardousness of a place. Pollution and outdoor recreation, including beach use on the Great Lakes, and water pollution as a hazard to health of swimmers.

Selected work on floods, droughts, earthquakes, tornadoes is being performed at Clark University, Worcester, Mass. (R. W. Kates), University of Chicago (G. F. White) and Southern Illinois University, Carbondale, Illinois (Duane Bauman).

SUPPORTED BY U.S. National Science Foundation

2.1800, WORKSHOP ON RESEARCH PROBLEMS IN AIR AND WATER POLLUTION
W.E. BRITTIN, Univ. of Colorado, School of Arts, *Boulder, Colorado* 80304

It is proposed to hold a workshop of one week's duration on fundamental research problems in water pollution, followed by a similar program for air pollution. The contents of the workshops would be addressed to physical and biological, basic and applied research scientists. Highlighting the workshops will be addresses by outstanding authorities in such subject areas as effects of long term, low level exposure to pollutants, eutrophication, thermal pollution, fate of pollutants in the hydrosphere, micrometeorology, tropiospheric chemistry, and others. Specific emphasis will be placed on unanswered basic and applied research questions as contrasted to purely technological and legal questions. Although the workshops will be divided into sessions on air and water pollution, its major thrust will be directed toward the planning of overall environmental research programs. The need for such a workshop is based on the recognition that many fundamental scientific questions remain unanswered with the result that many regulatory programs already enacted or being conceived do not have sufficient scientific basis. Accordingly there is wide disagreement among scientists as to the relative biological risks of pollutants. A monograph containing the lectures of the distinguished speakers will be published. It is expected that the research identified will involve interdisciplinary problem-oriented efforts. The organizers of the workshop will be in close contact with personnel headed by Dr. Gilbert White. Thus the proposed workshop has a far broader significance than the mere discussion of air and water pollution problems.

SUPPORTED BY U.S. National Science Foundation

2.1801, GREATER ANCHORAGE AREA BOROUGH, ALASKA
E. DOBROVOLNY, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

States to which project pertains: Alaska.

In consequence of the geologic effects of the Alaska earthquake of 1964 and its impact on land development, local government officials asked the U.S. Geological Survey for additional geologic work deemed necessary for Borough-wide planning. To meet this request, a general geologic map on a scale of 1:63,360 has been prepared and is now in the final stages of compilation for the Greater Anchorage Area Borough, which encompasses about 1,750 square miles. Study of Quaternary deposits is emphasized because most land-use development is concentrated on them. Special-purpose maps, such as slope stability, construction materials, and foundation and excavation conditions are being prepared from the general geologic map for use by planners and developers. The geologic work is closely coordinated with hydrologic investigations being conducted by the USGS Water Resources Division. Data developed by these combined studies are adequate to establish patterns of geologic and hydrologic relationships applicable to regional planning. For specific site development, however, more detailed and intensive investigation is required.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.1802, PLANNING AND SPECIAL STUDIES
D.A. HOFFMAN, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

A general, long-range approach is necessary for developing a coherent and purposeful water quality program. As one of the necessary steps in developing such a program, new studies of particular phases of the overall program will be explored and, where applicable, developed into individual programs. Proper integration with the work of other groups will be required, and an overall program will be coordinated with all of the Bureau programs and with related studies of Federal, State, and Local agencies. In order to fully accomplish these objectives two programs have been set up under this program: 1. Coordination and Planning - Division of Research personnel will attend meetings, conferences, and symposiums which pertain to the Bureau's water quality and ecology research program. Coordination meetings with other Denver personnel will continue. A meeting with regional personnel will be held in order to maintain awareness of regional problems. The research program will be evaluated to determine if it is meeting the Bureau's needs and responsibilities. Planning meetings will be held to develop a seminar concerning water resource projects and ecology, to be co- sponsored with the American Institute of Biological Sciences: 2.Special Studies - A review of the literature concerning the state of the art and research needs of reaeration was conducted in-house. A seminar will be held for Denver Office engineers and scientists by Dr. Krenkel of Vanderbilt University and Dr. Tsivoglou of Georgia Institute of Technology. The results of the literature review and seminar will be used to develop future applications of this technique for water quality enhancement. Research will be conducted in improving the techniques for collecting and analyzing unique water quality parameters with emphasis on heavy metals associated with mine drainage.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.1803, GEOLOGY OF URBAN DEVELOPMENT
H.E. MALDE, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

States to which project pertains: New Mexico.

Objectives: 1. Calibrate existing geologic factors in large unspoiled tracts vulnerable to development and thereby begin long-term appraisal of effects of urban impact. 2. Prevent future urban problems by making geologic data available for immediate designs in land use. 3. Interpret geologic data for use by planners in adding strength to zoning standards, grading specifications, and building codes. 4. Assemble information on the geologic methods adopted and their application and results as an example of work to be considered in other areas subject to urban impact.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.1804, VALUE OF DESALTED WATER FOR IRRIGATION
H.L. PARKINSON, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

Three irrigated study areas, located near Yuma, Arizona, Phoenix, Arizona, and Thermal, California, are being studied at reconnaissance level to determine the value of various water quality levels for irrigation. Improved water quality would be achieved by desalting brackish water in the 2000-5000 ppm range. Water quality levels of 50, 400, 900, and 1500 ppm are being studied. Desalting costs are being developed for both electrodialysis and multistage flash methods. Efforts are being made to maximize the possible benefits. Soil salinity is being held at optimal ranges for maximum production of selected crops by utilizing an adequate amount of deep percolation. Crop enterprise budgets are being used to evaluate potential direct benefits. Crop selection is carefully done to assure the best net income at each water quality level. Crops vary some between study areas. Yield levels are projected to 1990 for benefit evaluations.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.1805, ECONOMIC AND INSTITUTIONAL ANALYSIS OF WATER QUALITY STANDARDS AND MANAGEMENT
K.C. NOBE, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00010)

OBJECTIVE: Review, describe and analyze the legal and institutional settings within which the present Colorado Water Pollution Control Program developed, and appraise for efficiency and effectiveness the standards created. Develop an economic model for analyzing the efficiency of alternative methods and levels of water quality management. Determine optimum methods and levels of water quality management for selected areas in Colorado and the nature, incidence and magnitude of benefits and costs with agriculture as the source or recipient of pollutants. Assess the economic efficiency of state and federal water quality standards as related to situations studied and suggest guidelines for revision where appropriate.

APPROACH: Collect information on state and federal laws, regulations and standards on water quality management and data on institutional structures in use. Collect data on pollution and control from selected areas. Evaluate the legal and economic data collected. Analyze alternatives for modifying water quality standards over time, subject to data constraints, so as to take into account economic efficiency as a decision making criterion. Prepare project report.

PROGRESS: A compilation of federal and state water quality standards, laws, and regulations. A review of the related literature and research. Hydrological data on this area will be obtained from Gaylord Skogerboe, Agricultural Engineering, Colorado State University, who has done extensive research in that geographic area and is willing to cooperate in our research effort. Conferred with researchers of various disciplines at Colorado State University and other institutions who are working with this subject to discern the available technical data collected. Discussed this subject with the Colorado Water Pollution Control Commission and the Federal Water Pollution Control Agency, Denver Office, to discern institutional conditions, relationships, and possible constraints preventing more effective water quality control, and to obtain information regarding data and problem areas needing emphasis.

SUPPORTED BY Colorado State Government

2.1806, A STUDY OF LEGAL AND ADMINISTRATIVE PRACTICES RELATING TO LAKE POLLUTION IN THE NORTHEAST
W.C. KENNARD, Univ. of Connecticut, School of Agriculture, *Storrs, Connecticut* 06268

To identify major legal problems relative to lake pollution in the Northeast United States, generally, and Connecticut, in particular. To establish basic criteria for consideration in the formulation of policies and methodologies for the enactment of legislation in the area. To fulfill the objectives cited, it will be necessary to: Engage in a detailed and exhaustive review of judicial decisions applicable to the water quality of inland lakes, with particular reference to Connecticut water jurisprudence. Engage in a detailed and exhaustive review of existing legislation applicable directly or indirectly to inland water quality, with particular reference to legislative developments in Connecticut. Resources will include: state and federal reporter systems; state and federal statutes; federal proposals and committee reports; relevant literature including, but not limited to, federal research studies, state and local research, reports of land planning agencies, reports of conservationist organizations; technological journals, texts. Solicitation of information from state agencies which have been concerned with these problems.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1807, EFFICIENT PRICING FOR URBAN WASTE WATER RENOVATION - PHASE I
R.L. LEONARD, Univ. of Connecticut, School of Agriculture, *Storrs, Connecticut* 06268

The proposed research will identify for selected urban waste water renovation plants the impact of each major industrial waste component on the effectiveness of the treatment process and on operation and maintenance costs. Additional objectives include: identification of process changes and additions needed to produce a satisfactory final effluent, estimation of added costs resulting from treating various amounts of each major industrial waste, and development of pricing systems which will promote an effective and efficient combination of industrial waste control at the source and final treatment at the municipal plant.

Known methods of pricing based on allocating costs to volume, biochemical oxygen demand, and suspended solids are not applicable in urban areas producing complex wastes which impede the treatment process.

Two activated sludge plants receiving plating wastes have been selected for detailed analysis. The operation of these plants will be simulated through the use of a digital computer program. A simulation model developed for a conventional activated sludge plant will be modified to include the effect of plating wastes. The unit process characteristics will be determined by measuring 'as built' dimensions of equipment and by measuring flow, temperature and concentration of material between unit processes. Current prices in the area will be used in estimating cost relationships.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1808, WATER RESOURCES MANAGEMENT IN DELAWARE
F.X. TANNIAN, Univ. of Delaware, Division of Urban Affairs, *Newark, Delaware* 19711

The proposed research aims to evaluate the direct and indirect costs and benefits of water management agencies in Delaware. 1. The Delaware Water and Air Resources Commission. 2. The Delaware Public Service Commission. 3. The Delaware Department of Public Health.

A second and related objective is specification of small town voting rules for sewer and water investment decisions in Delaware.

2. WATER QUALITY

The model or approach of the state agency review calls for identification and analysis of the following water market features: 1. Legal and informal agency objectives. 2. Regulations relating to water and sewer service operating decisions. 3. Regulations relating to water and sewer service investment decisions. 4. Implications of these regulations for water quantity, water quality, direct costs, direct benefits, indirect costs and benefits, pricing-taxing, inter- agency impacts.

Voting rule analysis will be accomplished through interviews and questionnaires in Delaware small towns.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1809, WATER CYCLES, WATER RESOURCES PLANNING, AND URBAN DEVELOPMENT AT ROOKERY BAY, FLORIDA

R.F. DASMANN, Conservation Foundation Inc., *Washington, District of Columbia* (C-1817)

Centering on a watershed, estuary and bay located near Naples, Florida, the project is intended to study means of reconciling the pressures of urban development with the necessity for preserving the quality of environment. There are two aspects of the study. One, under the direction of the Institute of Marine Science will investigate the hydrology, oceanography, water quality and ecology of the Rookery Bay system as it is subjected to the urban development. Hopefully the development will proceed in accordance with a plan previously designed by the Foundation and the Institute. This plan is intended to protect the natural environment of the Rookery Bay system while permitting urban development to take place. Even in the event that this plan is not followed and development proceeds along other lines, the project will provide measures of the changes that take place. The second aspect of the project is intended to study the politics, economics, and social attitudes involved in the decision-making process in the Rookery Bay region in order to develop information useful to other areas where urban development takes place in a similar water-oriented environment. This aspect of the study will be conducted by The Conservation Foundation.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1810, ENVIRONMENTAL QUALITY

UNKNOWN, Resources for the Future Inc., *Washington, District of Columbia* 20036

About six years ago, Resources for the Future began research on environmental quality, particularly on water pollution problems. From these initial studies has developed the beginning of a conceptual framework for analysis of pollution problems.

Results of the studies point to two central concepts. The first states that wastes are simply residuals from the variety of extraction, production, and consumption processes in which man engages. Residuals occur as gases, liquids, or energy and are discharged into or onto the air, water, and land. So long as the amounts of the residuals do not exceed the capabilities of these natural systems for absorption and regeneration, no serious harm is done. When they do, pollution is the result.

The second concept states that since matter cannot be destroyed, a major objective of residuals management must be a reduction in the total amount of wastes that is generated, through a reduction in the total input of material in the system.

Scientists of Resources for the Future are now seeking to complete and refine the conceptual framework. One approach will be a series of individual studies, including such topics as how the decision-making structures in a democratic society are related to efficient environmental quality management and how reasonably accurate projections of residuals can be made on a regional and national basis. Another project will be to construct a computer model capable of examining a variety of management strategies in terms of their costs, benefits, and distributional implications. A third approach will be to make case studies of certain defined geographic areas. In the latter approach, Resources for the Future plans to involve itself with local groups; in that manner, local capabilities, and perhaps a regional laboratory, would be developed that could continue an analysis of the environmental problems of the region.

SUPPORTED BY Rockefeller Foundation - New York, N.Y.

2.1811, URBAN INFRASTRUCTURE INVESTMENT IN DEVELOPING COUNTRIES

L. WINGO, Resources for the Future Inc., *Washington, District of Columbia* 20036

The identities are being sought of the determinants of investment in urban public facilities in developing countries with special attention to the Latin American experience. The principal areas considered are housing, school facilities, transportation facilities, public buildings, public health facilities, and water and sewerage. A crucial part of the study involves statistical analysis of the economic characteristics of the urban areas of Chile as they relate to the country's existing stock of urban public facilities.

Document provided by Highway Research Information Service.

SUPPORTED BY Resources for Future Inc. - Wash., D.C.

2.1812, ENVIRONMENT AND TECHNOLOGY ASSESSMENT

J.L. LIVERMAN, U.S. Atomic Energy Commission, *Washington, District of Columbia*

The program attempts to evaluate the impacts that technology has had on the environment and to explore ways to reverse or prevent such impacts in the future. The program is concerned with environmental assessments of electrical energy, its generation and use, materials (i.e., toxic substances) and of waste management techniques. It also focuses on the development of research methods and analytical techniques relevant to achieving these assessments. These include an environmental information system, regional modeling, environmental indices, and education and communication. The problem assessment activity relies heavily on case studies and on continuous problem monitoring and evaluation. It is also related directly to analytical and laboratory research efforts which include: (1) total social cost of electrical energy, (2) trace element profiles through coal fueled plant; (3) econometric demand-supply model; (4) convergence of social and market equilibria; (5) analysis of abatement costs; (6) waste heat utilization; (7) alternative patterns in energy use; (8) rapid, high- sensitivity x- ray fluorescence for analysis of toxic heavy elements; (9) ecology of toxic metals; (10) toxic metals and lake and river sediments; (11) substitution technology for toxic and critical materials; (12) materials in aqueous streams; (13) environmental mutagenesis studies; and (14) techniques for measuring the mutation rate in man. The goal of the program is to understand the options (both technological and social) for societal choice in environmental problem solving. Crucial to this goal is the distillation of information necessary to produce clearly stated alternatives and their associated consequences.

SUPPORTED BY U.S. National Science Foundation

2.1813, LEGAL ASPECTS OF WATER RIGHTS IN THE EAST

H. ELLIS, U.S. Dept. of Agriculture, Natural Resource Econ. Div., *Washington, District of Columbia* 20250 (NRE3-2-54-00)

OBJECTIVE: Review, analyze, and compare the development and current status of laws applicable to water rights and regulation in the 31 Eastern States. This includes the States lying east of the Mississippi River and along its western border.

APPROACH: Analyses are made of state and federal statutes, constitutional provisions, court decisions and other factors applicable to water rights and regulation such as administrative regulations and contractual agreements, problems in acquiring or exercising private or public rights to use various sources of water for agricultural and other purposes, relationships to economic and physical factors, interstate and international considerations, and possible improvements in the applicable laws or their operation. The findings may be published separately for individual states or in reports that cover and compare all or several of the states.

PROGRESS: A paper was published discussing developments and issues concerning water rights regulation in the 31 Eastern States, including a discussion of court-made private and public water rights; contractual arrangements; permit systems and other regulations of water use, development or pollution and lake levels; and emerging issues. A summary and detailed report published on Indiana water law includes analyses of relevant court decisions, legislation, administration of water-use laws in Indiana, and suggestions for legislative action. A report on institutional arrangements for supplying and distributing irrigation water in North Dakota in the Garrison Diversion Unit, Missouri River Basin project, was also published including contractual arrangements between the Bureau of Reclamation, the Garrison Diversion Conservancy District, and irrigation districts. A manuscript on water- use law and administration in Wisconsin, in final publication stage, discusses the development of court decisions and the role of different levels of government concerning water use in Wisconsin, including an examination of the actual administration of a number of statutory laws. Other work in progress includes a supplemental national bibliography on water-law publications and a bibliography on federal-state jurisdictional questions.

2.1814, AIDS FOR WASTEWATER SYSTEM PERSONNEL SAFETY AND ADVANCEMENT
G.W. BURKE, U.S. Dept. of the Interior, Federal Water Quality Admin., *Washington, District of Columbia*

In this project expert consultants will prepare informational materials describing the use of recommended practices in maintaining safety and in testing certifying qualified personnel in water pollution control facilities. The consultants will study selected programs and evaluate the pros and cons on each program.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1815, WATER LAW OF SOUTHEASTERN ESTUARIES
M.W. COLLINS, Univ. of Georgia, Inst. of Government, *Athens, Georgia* 30602

This will be a comprehensive survey of the estuarine water law of Louisiana, Mississippi, Alabama, Florida, Georgia, and South Carolina. The resulting monograph of approximately 300 pages would draw conclusions as to the extent to which the law of these jurisdictions (1) protects commercial fishing and public recreational uses against deleterious competing uses such as pollution, land-fill, and dredging, (2) is related in this respect to the law of bordering states and to the federal regulatory power in marginal and territorial seas. Conclusions will be drawn as to overlaps, gaps, and conflicts of the present law. These can provide bases for remedial state and federal action to restore and preserve the estuaries of Southern states. The study can assist similar research in other regions of the United States.

2.1816, EVALUATION OF BENEFIT-COST ESTIMATION OF THE ECOLOGIC AND ECONOMIC IMPACTS FROM WATER RESOURCES CONSERVATION AND DEVELOPMENT
R.M. NORTH, Univ. of Georgia, Inst. of Natural Resources, *Athens, Georgia* 30601

The purposes of this research are to evaluate the effectiveness of the benefit-cost estimation of water resources conservation and development projects and to identify values and procedures which will more fully account for positive and negative changes in the ecology and economy of areas affected by project development.

The specific objectives of this research are: (1) To compare the actual and estimated benefits and costs accruing to project design purposes; (2) to estimate certain associated ecologic and economic changes induced by projects which were not enumerated in project formulation and planning; and (3) to suggest methods and values for expanding benefit-cost considerations to additional ecologic and economic impacts expected from future projects.

Data collection and analyses will be concentrated on a selection of representative projects in several physiographic regimes of the Southeast. Emphases will be placed on the selection of completed small watershed projects. The analyses will consider (1) investment costs, (2) OMR costs, (3) alternative costs for achieving similar project purposes, and (4) associated costs such as the loss of wildlife habitat and product. Comparative analyses of these costs will be made with (1) direct benefits from each purpose, (2) benefits from alternative methods of achieving project purposes, and (3) associated benefits such as improved wildlife habitat or product.

2.1817, ANALYSIS OF LAND USE PATTERNS - DOCTORAL DISSERTATION RESEARCH
G.L. PLUMMER, Univ. of Georgia, Graduate School, *Athens, Georgia* 30601

This dissertation research is on analysis of land use patterns in Georgia. The study will determine the applicability of phytosociological concepts at the community-ecosystem level and will include human as well as natural communities. Reference points will be established that might be used for predicting changes in the ecosystem composition.

SUPPORTED BY U.S. National Science Foundation

2.1818, A STUDY OF PUBLIC ATTITUDES AND MULTIPLE OBJECTIVE DECISION CRITERIA FOR WATER POLLUTION CONTROL PROJECTS
G.J. THUESEN, Georgia Inst. of Technology, Environmental Resources Center, *Atlanta, Georgia* 30332

The objective of the proposed research is an investigation of quantitative methods for translating public attitudes and conceptions about water pollution into criteria that will be useful in planning pollution control projects. These methods will include various analytical techniques including mathematical programming, Bayesian statistics, decision theory, Markov chains, and simulation. In addition, the decision criteria developed will be evaluated in order to determine its effectiveness as decision aids in the planning process. The evaluation of these criteria will be accomplished by comparison of its effectiveness when applied to simulated decision problems.

2.1819, ILLINOIS AND ITS INTERSTATE COMPACTS
M.E. RIDGEWAY, Southern Illinois University, Graduate School, *Carbondale, Illinois* 62901

Examination of the interstate compacts to which Illinois is a party, their legal status, agency and institutional arrangements, administrative powers and problems. Within determined limits, comparisons of Illinois' arrangements with those of other states to ascertain areas of possible improvements in control, direction, and achievement of compact proposals and goals. This study includes three interstate water compacts: The Ohio River Valley Sanitation Compact, the Wabash Valley Interstate Compact, and the Great Lakes Interstate Compact. Auxiliary to the water question is the Bi-State Development Compact of Illinois and Missouri. This latter compact also embraces metropolitan area problems, including water and air pollution.

SUPPORTED BY Southern Illinois University

2.1820, NETWORK EVALUATION OF WASTEWATER COLLECTION ECONOMICS
R.S. GEMMELL, Northwestern University, School of Technology, *Evanston, Illinois* 60201

Using a digital computer, a network model will be developed to represent the economics of wastewater collection as a function of urban form and structure. The basic objectives of the project are: (1) to test the hypothesis that waste-water collection network costs are a function of urban form and structure: city size, shape, pattern and the spatial distribution of people and activities; (2) to explore the cost behavior of sewer networks under different conditions of urban form and structure; (3) to explore the cost impli-

cations of simultaneous variations of urban size and density distribution of the population; (4) to develop a predictive model for wastewater collection network costs; and (5) to develop a methodology for evaluating the impact of planning decisions on sewer system costs. The research procedure is: (1) develop cost functions for network link components (pipes, etc.), (2) select network design criteria, (3) determine cost functions of network nodal components (manholes, pumping stations, private collection costs within buildings, etc.), (4) develop cost-sensitive measures of urban form and structure, (5) examine aggregate network cost functions and their correlation with the urban attributes previously developed, and (6) extract conclusions regarding costs and benefits of planning decisions relating to wastewater collection.

2.1821, PERFORMANCE OF REGIONALLY RELATED TREATMENT PLANTS

R.S. GEMMELL, Northwestern University, School of Technology *Evanston, Illinois* 60201

In planning for wastewater treatment facilities within a regional system, the question of the optimal degree of centralization of treatment facilities is of interest. There are two major considerations to be made in the answering of this question of the optimal degree of centralization. One is, how does centralization affect the economics of interceptor and outfall piping systems and plant construction and operation in the case of (a) centralized and (b) spatially separated treatment facilities? The other consideration is, what are the corresponding effects of many spatially separated effluent streams and a few centralized effluent streams on the receiving waters with regard to (a) the areal distribution of effluent streams and (b) independently fluctuating qualities of effluent streams?

To study the performance of regionally-related wastewater treatment plants, a performance model based on findings of an analysis of actual plant operations data is to be developed. The basic objectives are: (1) study and develop mathematical representations of the stochastic nature of individual wastewater treatment plant input and output parameters, (2) study and develop mathematical representations of the dependence of relative operating efficiencies among treatment facilities of a multiple plant regional system through developing a methodology for testing dependence and conducting tests on actual data, (3) apply the mathematical functions derived above to existing performance models of regional treatment plant systems, or (4) develop a performance model for a multiple plant regional treatment system based on the above findings, in the event that the models applied in (3) are inadequate. The model capabilities would include the determination of resulting water qualities and the economic impact of achieving those water qualities from alternative systems.

2.1823, ENVIRONMENTAL GEOLOGY OF BOONE AND DEKALB COUNTIES, ILLINOIS

J.P. KEMPTON, State Geol. Survey, *Urbana, Illinois* 61801

A report on the sand-and-gravel and dolomite resources of counties has been published and is available; the remainder of the information will be available when published. The rapid growth and development of Boone County and the northern half of DeKalb County have indicated a need to develop information on the geologic conditions related to land- use planning. This study will relate knowledge of the geologic conditions related to land-use planning. This study will relate knowledge of the geology, including occurrence of water and mineral resources (sand and gravel, dolomite, clay, borrow material, etc.) to urban and industrial growth, waste-disposal needs, open-space development, flooding, storm drainage, surface reservoirs, and general engineering conditions.

Published information on the bedrock geology and bedrock topography has been modified to present information on the area of occurrence and depth of the major bedrock aquifers and on dolomite resources. Subsurface and surface mapping have proceeded to outline the stratigraphy, distribution and character of the glacier deposits. Information on the glacial drift will be applied to evaluation of the occurrence of sand and gravel as a material resource and as aquifers and to the drift in general in terms of construction conditions and waste disposal.

Illinois State Geological Survey review, June 1970: Discontinued. DeKalb County published as Environmental Geology Note 33.

SUPPORTED BY Illinois State Government - Springfield

2.1824, DEVELOPMENT OF COST CRITERIA FOR WATER SUPPLY

J.H. DAWES, State Water Survey, *Urbana, Illinois* 61801

An effort is being made to develop cost data criteria to be applied in comparisons of alternative water resources developments. These criteria will be extracted from actual cost data collected from federal, state, municipal, and private agencies. The study encompasses impoundments, well supplies, and transmission facilities. Although the study is being made for Illinois, the purpose and format of its results should be of general interest.

Completed as of August 1969 were the following technical letters: No. 7, Water Transmission Costs; No. 8, Cost of Reservoirs in Illinois; No. 9, Cost of Pumping Water; No. 10, Costs of Wells and Pumps; No. 11, Cost of Water Treatment in Illinois; and No. 12, Sewage Treatment Costs.

Cost studies are continuing for the development of working tools in our water resources development model that involves the capture, storage, treatment, distribution, reconditioning and recovery of water supplies.

SUPPORTED BY Illinois State Government - Springfield

2.1825, LAKE MICHIGAN WATER QUALITY MODEL

R.L. EVANS, State Water Survey, *Urbana, Illinois* 61801

The specific objective of the project is to develop a mathematical water quality model for Lake Michigan. Model formulation will be primarily based upon information regarding dissolved conservative mineral substances. The data will be from records that are available and will pertain to the chemical quality of rainfall, natural and man- made discharges, and waters of the lake. Changes in content as expressed by the model in relationship to economic growth, population shifts, etc., will serve as an instrument for water quality management.

SUPPORTED BY Illinois State Government - Springfield

2.1826, WATER QUALITY MODEL DERIVED FROM SYSTEM ANALYSES

R.L. EVANS, State Water Survey, *Urbana, Illinois* 61801

As a subsystem for an overall endeavor to develop a water management program for the Kaskaskia River Basin, the elements and their interrelations and interactions for a water quality model are being defined; once defined these elements will be used for developing a water quality model. The objective of the model will be to determine the degree of treatment required for each waste discharger in order to achieve a desired water quality objective at the minimum cost to all dischargers.

SUPPORTED BY Illinois State Government - Springfield

2.1827, WATER QUALITY CRITERIA FOR SELECTED RECREATION USES
D.W. BISHOP, Univ. of Illinois, Graduate School, *Urbana, Illinois* 61801

The proposed research plan involves laboratory and field investigations directed at the determination of water quality criteria for selected recreation uses. The objectives of the project are: I. To survey the types and extents of water pollution which are, or are considered to be, detrimental to selected water-oriented recreation activities of the residents of a six county area in East Central Illinois. A. To determine the beliefs and attitudes toward different types and extents of pollution for different activities (questions about what types and extents of pollution bother the respondents). B. To determine if choice of location for particular activities is related to physical measures of water quality. C. To determine types of pollution that users believe to affect their choices of sites for particular activities, and how the users conceptualize those pollutants. These problems are to be investigated for both on-site and off-site users. II. Water quality criteria for water oriented recreation, based on a combination of information from the survey and from existing quality standards; and to develop a rating scale, for selected recreation uses of water, based on the quality criteria.

The research will be conducted by survey questionnaires and interviews of users at recreation sites and at off-site locations. Statistical analysis may include Kendall's coefficient of concordance, differences in the mean or the number of cases, bivariate frequency tables, chi square analysis, and multiple regression techniques. Both chemical and biological tests of water quality will be made.

The survey method and methods for developing the water quality criteria and rating scale, if successful, will provide states, regions, other agencies and the nation with a tool to survey their residents, test their waters and develop comprehensive water qualiy criteria for recreation.

2.1828, ECONOMIC EVALUATION OF THE EFFECT OF SELECTED CROP PRACTICES ON NON-AGRICULTURAL USES OF WATER
G.R. SWANSON, Univ. of Illinois, School of Agriculture, *Urbana, Illinois* 61801

A watershed in Illinois will be selected for an economic analysis of the effect of crop production practices on the quality of receiving waters. The concept of a watershed firm will be used. The criteria for choice of crops and management practices will be maximization of net farm income subject to constraints of resources available on farms in the watershed, allowable limits of silt accumulation in reservoirs, and acceptable levels of pollution by chemicals originating from crop production practices. In the event that these constraints effectively limit otherwise economically optimal levels of crop production practices, estimates will be made of the cost of altering each of the effective constraints.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1829, A QUANTITATIVE ANALYSIS OF LANDSCAPE ESTHETICS, WITH SPECIAL REFERENCE TO STREAM AND VALLEY SYSTEMS AND RELATED WATER AND LAND RESOURCES
W.N. MELHORN, Purdue University, School of Science, *Lafayette, Indiana* 47907

Development of the National Objectives Accounts has placed importance on environments and human well-being, supplementing the former emphasis on economic activity and growth in productivity. To assist the decision-making process regarding disposition and handling of water and related land resource projects, numerical data concerning the environment must be obtained for input into accounting procedures as conventionally done with technical and economic parameters.

Leopold has proposed a method designed to quantify esthetic features of environment. Using 46 field-evaluated descriptive categories of physical, biologic and water quality, and human use and interest factors, a 'uniqueness ratio' is determined for each stream segment, valley, or site. The system subdues or eliminates personal subjectivity and produces an objective numerical description for each stream or valley studied. The numerical value can be related directly to the environmental and human-well being factors of the objectives accounts.

Indiana basins and streams will be studied by the Leopold method, and additions, deletions or modifications made as appropriate to a mid- latitude temperate climate as opposed to the 'wild rivers' studied originally by Leopold. The results will provide quantitative data either supporting need for technical development of undeveloped water resources, or conversely provide numerical arguments favoring environmental protection.

2.1830, ECONOMIC ANALYSIS OF OPTIMAL WATER QUALITY MANAGEMENT
A. WHINSTON, Purdue University, Graduate School, *Lafayette, Indiana* 47907

The overall objective of the research proposal is the further development of the methodology and techniques of economic analysis as applied to water pollution. In particular, a substantial part of the work will attempt to apply these techniques to the White River.

The specific parts of the project may be listed as follows: 1) The development of steady state transfer functions for parts of the White River. 2) The formulation of water quality management models. 3) The development of mathematical techniques to solve the water management problems. 4) A study of the economics of a regional treatment system. 5) An extension of the model to the time variable case.

2.1831, TECHNOLOGY AND ECONOMICS OF CONSERVATION
P.E. ROSENBERRY, Iowa State University, U.S.D.A. Nat. Resour. Ec. Div., *Ames, Iowa* 50010 (NRE2-8-16-01)

OBJECTIVE: Determine and evaluate the economic aspects of current and developing technology of water management. This will include evaluating the effectiveness of alternative terrace systems and other land treatment measures in managing the flow of surface water to more effectively utilize precipitation in crop production through control of runoff, reduce soil fertility losses from sheet erosion, control gully growth, and reduce downstream sediment and flood damages. Associated effects which will be analyzed include the maintenance or improvement of soil productivity, pollution abatement, efficiency of machinery use, and the land area removed from production as a result of the water management measures adopted.

APPROACH: The first step will be a comparative cost study of alternative types of terraces as applied in the North Central Region. The analysis will consider slope, soils and methods of construction. The large, parallel, grassed-backslope terraces currently receiving widespread acceptance will receive particular attention. Additional studies will evaluate the effectiveness of representative terrace systems and other measures in producing various on-site benefits.

PROGRESS: Data on the construction cost per foot of grass backslope (GBS) terraces have been collected cooperatively with SCS in North Central Iowa since 1964. Initial analysis of the data indicated that the number of cubic yards of earth moved per linear foot of terrace was an important variable. Since hand computation of this variable was impractical, a model was designed with sufficient equations and interrelationships to handle the various terrace site situations and applied in computing cubic yards of earth needed per linear foot of terrace and the cubic feet of water storage for various terrace designs and ground slopes. Work related to the Treynor experimental watershed of ARS in southwest Iowa was reviewed in an oral presentation at the Mid-central meetings of the American Society of Agricultural Engineers in St. Joseph, Mo. The paper discusses the economic factors involved in a comparison of a terraced and unterraced watershed, in addition to topography, climatology and hydrology data.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Agriculture

2.1832, WATER RESOURCE DEVELOPMENT
J.F. TIMMONS, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01445)

OBJECTIVE: Develop an economic basis for allocating water among competing uses and users, investigate possibilites of structural means for developing water resources and sharing costs and benefits.

APPROACH: Uses of water from particular supply sources, i.e., aquifers or impoundments, will be identified. Productivities of water in various uses will be determined. Competitive and complementary ranges of uses will be identified. Effects on water quality by uses will be investigated with the costs of maintaining quality of water for re-use.

PROGRESS: Work proceeded on water quality management with particular reference to agriculture based upon sedimentation. Studies means were developed for tracing the causes and effects of various effluents arising within agriculture. Alternative means for assigning values to various qualities of water for purposes of allocation were identified and appraised. Methods for identifying and approximating demands and supplies of water of various qualities were developed.

SUPPORTED BY U.S. Dept. of Agriculture

2.1833, BALANCED STORM DRAINAGE
J.S. MCNOWN, Univ. of Kansas, School of Engineering, *Lawrence, Kansas* 66044

Rainwater flows on roadways, in gutters and through storm drains on its way to storm sewers. Selection of a design storm and analysis of consequent run off provide a value for the flow to be handled successively by the surface and underground systems. Despite resultant uncertainties in the quantity of flow to be handled, the system still should handle the expected flow efficiently, be economically designed, be free from hazards caused either by ponding in traffic lanes or irregularities on the surface, and satisfy such diverse requirements as safety to pedestrians and self cleaning from brush, silt and leaves. Finally, the system should not unduly restrict traffic for storms which exceed the design value.

Present practice is well defined only for the series of inlets tested at Johns Hopkins with flush and depressed horizontal gratings. Additional study is required for curb-inlet openings and various combinations of Froude number, slope, alignment curvature, grating arrangement and approach flow. For example, small indentations upstream from the opening can significantly increase the effective length simply by allowing flow curvature to begin before the opening itself is reached. Such factors will be analyzed and tested in the laboratory after study of current practice and laboratory investigations.

2.1834, THE POLITICAL AND ADMINISTRATIVE PROBLEMS OF INSURING APPROPRIATE RESIDENTIAL SERVICES IN THE PERRY AND CLINTON RESERVOIR AREAS
S.M. WYMAN, Univ. of Kansas, Graduate School, *Lawrence, Kansas* 66044

This study is focused on political and administrative problems facing local governments responsible for controlling the impact of residential development on water quality in the Perry and Clinton reservoir areas in Kansas. Significant constraints on both the local governments and other parties involved in development will be identified and described. These descriptions will be based on attitude surveys of developers, small parcel owners, and state and local government officials regarding improvement costs, tax burdens, and changes in governmental policies, structures and powers. A review of the limitations and opportunities for reform existent in current statutes will also be conducted as will a comparative study to identify governmental patterns and procedures which have been effective at other Midwest reservoirs. A report will be written containing problem descriptions and recommendations for their resolution. This report will be designed for use by developers, governmental officials and interested citizens.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1835, A DETAILED INVESTIGATION OF THE SOCIOLOGICAL, ECONOMIC, & ECOLOGICAL ASPECTS OF PROPOSED RESERVOIR SITES IN THE SALT RIVER BASIN, KENTUCKY
L.A. KRUMHOLZ, Univ. of Louisville, Water Resources Laboratory, *Louisville, Kentucky* 40208

The impoundment of the Salt River to form Taylorsville Reservoir has been authorized and the advanced engineering and design underway. Construction of the dam three miles upstream from Taylorsville, Kentucky, is scheduled to begin early in 1971. This is the first of a series of three impoundments proposed for the Salt River Basin.

The overall project will include detailed studies of the impact of such impoundments on the biological, sociological, agricultural, and economic characteristics of the areas to be impounded and their environs. The biological phases of the project will include detailed ecological studies of the aquatic environment and the contiguous terrestrial areas. Sampling the biota and collection of physical and chemical data have been underway for more than a year and will continue at biweekly intervals at 20 stations throughout construction of the dam, clearing the reservoir site, impounding the water, and for at least 5 years after impoundment. Changes in water quality and in the biota will be documented as they take place.

This project extends and broadens the biological, physical, and chemical phase of the investigation into its third and fourth year. The sociological phase of the study is underway under the direction of Drs. Henry F. Dobyns and Rabel Burdge of the University of Kentucky. Economic studies of the area will continue under the supervision of Dr. John P. Nelson of the School of Business, University of Louisville.

2.1836, STUDY OF A RIVER SYSTEM AS A CHEMICAL REACTOR (PHASE II)
E.C. BOALEK, Univ. of Maine, School of Technology, *Orono, Maine* 04473

Phases I and II involved an experimental plan, grounded in a base of chemical reactor control theory. This plan guided design, construction, and field testing of necessary hardware systems for continuous monitoring, transmission and processing of data necessary to implement a new concept for programming pollution inputs in balance with the variable capability of the river to purge itself by oxidation reactions. Phase III projects an intensive program of data collection and analysis for the Penobscot River to provide an empirical base for decisions on: 1. The value to the control scheme of the presently projected river model compared to alternative models which can be developed using the same experimental data; and 2. Reconciliation of technical feasibility with economic consequences in implementing controls for a quality spectrum of attainable water specifications.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1837, ECONOMIC ANALYSIS OF ENVIRONMENTAL QUALITY EFFECTS ASSOCIATED WITH SEASONAL HOMES
D.M. TOBEY, Univ. of Maine, Agricultural Experiment Sta., *Orono, Maine* 04473

OBJECTIVES: Determine the environmental situations (positive and negative) associated with seasonal homes and analyze the attitudes, interests, and goals of people for a quality seasonal home environment. Evaluate the social and private costs and benefits of identified environmental situations at both the regional and national level. Determine the total potential market for seasonal homes in the Northeast and delineate the effects of environmental factors upon this market.

Approach. Case study method will be used in five selected areas: (1) Lake in organized township in Central Maine (2) Lake in densely populated area in Southern Maine (3) Lake in unor-

ganized township in Northern Maine (4) Community in densely populated coastal area in Southern Maine (5) Community in sparsely populated coastal area in Eastern Maine. For each selected area major factors analyzed will be air, water and scenic pollution. Causes will be related to methods of waste and sewage disposal and effects of unplanned land use. Systems analysis will be used to estimate social costs and benefits generated by environment effects. Benefit: cost ratio will be computed wherever possible.

Progress, 7/69 - 6/70: Investigators compiled taxation data from five seasonal home areas in Maine, a mixture of coastal and inland (lakeshore) communities. These data are being used for the construction of a sample of seasonal homes from which financial and attitudinal data will be collected.

Two communities were selected as study areas to be included in the regional research effort. Questionnaires, standardized for use throughout the Northeast region, were prepared to elicit attitudinal responses from officials, permanent residents, and seasonal residents of these communities.

SUPPORTED BY U.S. Dept. of Agriculture

2.1838, LEGAL ASPECTS OF WATER POLLUTION CONTROL THROUGH IMPLEMENTATION OF THE EFFLUENT CHARGE CONCEPT

O.E. DELOGU, Univ. of Maine, School of Law, *Portland, Maine* 04101

The three initial objectives of the study are: (1) to determine what legal constraints (if any) would burden or preclude the adoption of an effluent charge in Maine. (2) to design a suitable agency structure for imposing an effluent charge, administering the funds realized from such a charge, and adjusting the size of the charge to both quantity and quality of waste discharges and the costs over time of construction and maintaining the waste treatment facilities made necessary by the discharge of pollutant material into the state's waters. (3) to draft and submit to the legislature alternative legislative proposals for actual implementation of the effluent charge concept.

It is clear that the translation of the concept of effluent charge into a working program in any particular jurisdiction involves reducing abstract broad brush principles to detailed step-by-step implementing mechanisms, which must be consonant with the constitution, statutes, and administrative practices of the jurisdiction involved. The mechanics of handling the fund must be thought through and decisions as between state level construction of treatment facilities, regional (special district) construction of such facilities, or the local construction of such facilities must be made. Finally, the legislature must be presented with a series of alternatives each of which must be suitable to the jurisdiction and each of which must be supported by a commentary outlining the strengths and weaknesses of that particular approach.

This project will be completed during FY 1971.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1839, NORTHEAST VIRGINIA

L. PAVLIDES, U.S. Dept. of the Interior, Geological Survey, *Beltsville, Maryland* 20705

Major research objective is to study the geology of the outer Piedmont of northeast Virginia, and includes studies of the Coastal Plain and Triassic deposits where the quadrangle boundaries overlap into these two provinces. Closer dating of the Glenarm Series by determining the relationship of the Quantico Slate to the Arvonia Slate (mid-Ord.) is a prime topical objective. Supplemental objectives will include studies on distribution, thickness, and composition of saprolite; reconnaissance stream sediment sampling; evaluation of clay, sand, and gravel resources; and other general studies related to environmental problems. These will include complementing data obtained from geologic studies with analysis of existing soil maps to possibly evaluate factors such as suitability of land for urbanization with respect to sanitary waste disposal problems. It is hoped the environmental-oriented studies of this project will be of use to planners prior to the anticipated massive urbanization predicted for this general area (Washington-Richmond corridor).

2.1840, RESEARCH AND STUDY OF THE CHESAPEAKE BAY

R.W. KRAUSE, Univ. of Maryland, School of Arts, *College Park, Maryland* 20740

The research to be conducted under this project involves the initial implementation of a comprehensive research plan and research management methodology outlined in a report entitled 'The Chesapeake Bay: Report of a Research Planning Study', submitted to the National Science Foundation by the Johns Hopkins University, the University of Maryland and the Virginia Institute of Marine Science.

In the research program major attention will be directed toward the construction of a data bank for storage and retrieval of information classified according to an inventory methodology designed to identify all the significant entity interactions of the Chesapeake Bay, their respective processes and characteristics. Such information will assist in the management of the Bay and in delineating those areas of inadequate knowledge for which research is necessary.

A second objective is the application of systems analysis to the Bay and its components for a comprehension of its dynamics, its characteristics and its probable fate according to the choices made in the management process.

A third objective is initiation of an integrated research program in biology, physics and chemistry, economics, and sociology, behavioral sciences and institutions, including government and law.

In addition, specific problem areas and case studies will be the subject of intensive interdisciplinary research.

SUPPORTED BY U.S. National Science Foundation

2.1841, A METHODOLOGY FOR PLANNING OPTIMAL REGIONAL WASTE MANAGEMENT SYSTEMS

D.D. ADRIAN, Univ. of Massachusetts, School of Engineering, *Amherst, Massachusetts* 01002

A regional system of waste management encompasses several communities lying on the watershed of a stream which is used for effluent disposal. These communities may at present have various types of treatment plants. Regional planning is an attempt to maintain or to upgrade stream quality by expanding or adding new facilities while considering the region as whole rather than on a piecemeal, community by community basis. The expected outcome of this type of planning is the pooling or sharing of some facilities thereby significantly lowering the cost of meeting stream standards.

The overall objective of this research is to develop a practicable methodology for regional waste water management planning employing economic optimization techniques. It is proposed that this be done as follows:

A. Form a research team drawing personnel from several disciplines. B. Develop for each sub-system of the regional plan quantitative expressions defining and describing: 1. Physical relationships among variables. 2. Significant constraints on the subsystems 3. Cost functions. C. Construct over-all mathematical model integrating the above relationships. D. Adapt and develop techniques for model analysis and optimization. Code these techniques for a computer. E. Devise methods for testing the model in the absence of existing regional waste management plans and test the model in accordance with these methods.

2.1842, FORMATION OF PUBLIC POLICY ON OUT-OF-BASIN DIVERSION OF CONNECTICUT RIVER FLOOD WATERS TO BOSTON METROPOLITAN AREA

B.B. BERGER, Univ. of Massachusetts, Water Resources Research Ctr., *Amherst, Massachusetts* 01002 (C-2169)

The study will seek to answer two sets of questions: (1) How does public policy evolve in respect to this inter-basin transfer of water? Subordinate questions are: (a) How did the various in-

terested public groups form their opinions on this controversial issue? (b) How did the attitudes of these public groups change in time and what factors accounted for these changes? (c) How effective were public hearings in providing an opportunity for expression of public opinion? (d) What factors most strongly influenced the attitudes of the members of the special task force assigned by the General Court to the study of the proposed legislation? (2) What consequences in the Connecticut River Basin may reasonably be associated with diversions out of the basin? Subordinate questions are: (a) What is the role of flood flows in scouring bottom deposits? (b) What is the role of spring and autumnal flood flows in triggering movements of anadromous fish? (c) What is the role of flood flows in nutrient supply and removal? (d) What is the role of flood flows in the pollution of the river and its amelioration? (e) What is the influence of flood flows on the ecology of tidal and estuarial water? (f) What are the long-term water supply requirements of the basin region? (g) What is the role of Connecticut River flood flows in recharging regional groundwater aquifers important to the region?

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1843, EVOLUTION OF PUBLIC POLICY ALTERNATIVES IN MAXIMIZING PUBLIC BENEFITS RESULTING FROM WATER QUALITY IMPROVEMENT

J.H. MARTIN, Univ. of Massachusetts, Graduate School, *Amherst, Massachusetts* 01002

The objective of this proposed research will be to produce a model by means of which: 1. Increased values of water-related lands may be estimated as a result of water quality improvements. 2. The beneficiaries of these increased values with prevailing public policies on land use may be identified. 3. Alternative strategies may be described, by means of which these increased values may produce maximum public benefit. 4. A basis for prudent public policy may be recommended.

The study will be an attempt to show how the massive commitment of public funds may be best employed to serve certain varying-term objectives. How over the long-term the expenditures of funds may be realised as a massive capital investment in one of the nation's most valuable natural resources: its natural rivers, lakes and riparian lands.

Study area: The lower pioneer valley regional planning district of the Connecticut River in Massachusetts.

Work includes: 1. Examining public, private and commercial attitudes towards water, water pollution, and water pollution abatement. 2. Inventory and analysis techniques for water-lands. 3. Governmental structures and attitudes. 4. Models for water-land use planning: policies and strategies. 5. Case studies of application of models to selected water-land situations 6. Aesthetic factors.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1844, ECONOMIC ANALYSIS OF COORDINATED WATERSHED PLANNING

J.B. WYCKOFF, Univ. of Massachusetts, Agricultural Experiment Sta., *Amherst, Massachusetts* 01002 (MAS00281)

OBJECTIVE: Determine the private costs of meeting water quality standards in a selected watershed. Synthesize the cost of meeting water quality standards through coordinated planning of a watershed. Examine the institutional setting affecting coordinated watershed planning. Examine the social costs and benefits associated with alternative water quality levels.

APPROACH: A watershed within the state ordered to improve its water quality will be studied in detail. Each individual firm and community is essentially solving their own problem. The private costs involved will be determined. Public health records will be utilized to determine the quantity and quality of effluent discharge by each in the watershed and aggregated for the stream total. An optimum treatment system, planned on a coordinated watershed basis, will be programmed considering alternatives. The legal, political, social, and economic institutions affecting coordinated planning will be determined and evaluated. Implications of the existing institutions relative to the efficiency of coordinated planning will be studied. The social costs and benefits of water quality will be determined. The framework provided by welfare economics will be used to determine the net effects upon society.

PROGRESS: A recent legal decision has freed access to the remainder of the data needed for the project. This is now being collected and analysis is being completed. Although the analysis is not complete, preliminary indications are that the existing Federal regulations which must be met in order to qualify for Federal grants and aid may be resulting in the 'wrong' pollution control systems being built.

SUPPORTED BY U.S. Dept. of Agriculture

2.1845, DATA COLLECTION ECONOMICS FOR WATER POLLUTION CONTROL STUDIES

A.S. GOODMAN, Northeastern University, School of Engineering, *Boston, Massachusetts* 02115

Specific Aims - Water pollution control agencies have programs for collecting data and processing them in accordance with procedures that have evolved over the years. Due to the very large number of projects, it is desirable to make these programs more efficient and therefore less costly. It would be expedient for these agencies to know the relative importance of various field and laboratory data in making water and wastewater studies.

The proposed research expects to be able to indicate: (1) for portions of such programs, where field and laboratory techniques are well developed, the extent of sampling needed for useful results and (2) for portions of such programs where field and laboratory techniques are not well developed, the relative importance that ought to be placed on researching and developing such techniques.

Methods - Data used for predictive formulas and for program examination and enforcement would be classified. The intent would be to focus on data which are needed for mathematical analysis. Electronic computer studies would vary data within expected ranges and determine resulting river water qualities and economic effects. Other statistical and economic analyses would also be employed.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1846, WATER AND THE CITIES

E. MILLER, A B T Associates, *Cambridge, Massachusetts* (C-1469)

The proposed research is to: 1. investigate the question of the costs and the benefits of investment in pollution abatement aimed at expanding water recreation facilities, 2. to examine the potentialities of new directions in urban design that are made possible by the availability of waterfront land for other than transportation-oriented activity, 3. to conduct a reconnaissance into the technology of water supply and its alternatives to predict developing patterns of feasibility and highlight important trade-off margins among competing techniques and 5. to examine the industrial, aesthetic, residential, commercial and recreational interaction of an urban estuarial environment. Interim reports are available from: Edward Miller, ABT Associates, 55 Wheeler Street, Cambridge, Mass. 02138.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1847, THE ECONOMICS OF WATER SUPPLY AND QUALITY

R. DORFMAN, Harvard University, Graduate School, *Cambridge, Massachusetts* 02138

The objective of this research is to develop improved methods of planning water resource developments in situations where municipal and industrial water supply and pollution problems are significant.

This work is comprised of three essential parts. First is the study of the economics of water pollution abatement at the waste source and the construction of functions which reflect the losses and benefits associated with alternative abatement measures such as low flow augmentation, long-distance waste transport and in-stream treatment. Second is the study of the economics of municipal and industrial water supply and the development of improved benefit and loss functions for water system performance.

Finally these economic functions will be incorporated into simulation models of the Delaware River basin and estuary with the objective of developing improved methods for planning water supply and pollution abatement policy.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1848, INPUT-OUTPUT ANALYSIS OF GENERATION AND ELIMINATION OF POLLUTION IN THE UNITED STATES ECONOMY

W.W. LEONTIEF, Harvard University, School of Arts, *Cambridge, Massachusetts* 02138

The proposed exploratory research involves approach to empirical implementation of a model described in a paper, Environmental Repercussions and the Economic Structure: An Input/Output Approach, in the Review of Economics and Statistics. The objectives of the proposal are: 1) an extension of the present input/output matrices for the American economy, by the addition of appropriate numbers of rows representing sector-by-sector emission of different types of pollutants and columns representing anti- pollution processes; 2) projection of these pollution and anti- pollution coefficients in 1980 or 1985; 3) analytical use of the new data base thus created in a quantitative assessment of principal types of pollution and in the analysis of changes and activity levels of various sectors of the economy that will result from alternative combinations of anti-pollution methods.

A specific agenda for further analytical and empirical work on pollution will be a primary output of this exploratory research effort.

SUPPORTED BY U.S. National Science Foundation

2.1849, MANAGEMENT ASPECTS OF THERMAL POLLUTION CONTROL

D.H. MARKS, Mass. Inst. of Technology, School of Engineering, *Cambridge, Massachusetts* 02139

The effect of environmental constraints such as stream temperature standards on thermal power investment and location decisions is investigated. A location model is developed which shows optimal location of plants and equipment choice from an efficiency point of view while meeting environmental constraints. Thus, the model may be used to show how costs and decisions change as environmental standards change. Additional work on the type of temperature models needed for precise evaluation under different conditions, the effects of stream geometry on outfall design, and the trade-off between location and additional investment in different types of heat abatement equipment is also to be carried out.

SUPPORTED BY Massachusetts Inst. of Tech. - Cambridge

2.1850, MATHEMATICAL WATER QUALITY PLANNING MODELS

J.C. SCHAAKE, Mass. Inst. of Technology, School of Engineering, *Cambridge, Massachusetts* 02139

Three mathematical models are being developed and applied to determine optimal schemes for investing in facilities to control water quality in the Boston Harbor. Feasible facilities include storage space for storing combined sewer overflows, treatment facilities for treating municipal and industrial wastes, and diversion facilities for distributing wastes (treated, untreated, and combined overflows) throughout the harbor. The models include: a mathematical programming model for determining optimal investment schemes; a waste transport model for estimating coefficients for the mathematical programming model, and a tidal current model for estimating currents for the waste transport model.

SUPPORTED BY Massachusetts Inst. of Tech. - Cambridge

2.1851, SUPPORT OF TWO RESEARCH VESSELS

D.C. CHANDLER, Univ. of Michigan, Great Lakes Research Division, *Ann Arbor, Michigan* 48104

This project provides operating support for two vessels belonging to University of Michigan and utilized by the staff from that institution and others located around the Great Lakes. They are employed for regional Sea Grants programs being carried out by U. of Michigan and U. of Wisconsin.

These vessels will be used for biological, physical and chemical monitoring of Lake Michigan, deep water current studies, river plume studies, thermal pollution studies, and sediment coring.

SUPPORTED BY U.S. National Science Foundation

2.1852, COLLABORATIVE PROGRAMS WITH GOVERNMENT AND PRIVATE AGENCIES FOR SOLUTION OF ENVIRONMENTAL PROBLEMS

UNKNOWN, Univ. of Michigan, Graduate School, *Ann Arbor, Michigan* 48104

No summary has been provided to the Science Information Exchange.

SUPPORTED BY W.K. Kellogg Foundation

2.1853, DEVELOPING BROADLY COHERENT MULTIDISCIPLINARY RESEARCH AND GRADUATE TRAINING PROGRAMS IN ENVIRONMENTAL QUALITY

UNNOWN, Univ. of Michigan, Graduate School, *Ann Arbor, Michigan* 48104

The quality of the human environment is deteriorating rapidly. Simplistic solutions, dealing with only one or a limited number of factors, are no longer effective: the need now is for a holistic approach. The University of Michigan, long a leader in environmental studies, is developing problem-oriented, multidisciplinary research and training programs focused on the totality of man's environment and on its preservation and improvement.

A center for environmental quality is planned, to be responsible for all programs of research and training. Activities within specific departments and schools will continue, but the center will initiate, encourage, and support multidisciplinary efforts.

Graduate programs in pertinent fields, such as forestry, waste disposal research, hydrology, and ecology, will continue. In addition, emphasis will be placed on devleoping broad undergraduate courses on man and his environment.

SUPPORTED BY Rockefeller Foundation - New York, N.Y.

2.1854, AN ENGINEERING ECONOMIC STUDY OF RECLAMATION AND MULTIPLE REUSE AS A WATER SUPPLY ALTERNATIVE

W.J. WEBER, Univ. of Michigan, School of Engineering, *Ann Arbor, Michigan* 48106

The research will consider the engineering economics of total water usage through water reclamation and recycle. The feasibility and economic boundaries of recycle will be examined using idealized water- use models for municipalities and firms. The effects of available water quality and pollution control standards will be investigated as factors that directly influence decisions to use water reuse as a distinct water supply alternative. Pollution and quality constraints typical of various water use settings will be used in the model.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rcn.

2.1855, IMPACT OF WATER QUALITY CONTROLS

C.R. HUMPHRYS, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00914)

OBJECTIVE: Analyze the impact of water quality standards on uses of water in agriculture and the impact of agriculture practices on the quality of the waters available for use by others.

APPROACH: Study of impact of use of waters of varying quality on agriculture. Study of impact of agriculture practices on the quality of the water supplies available for other uses.

PROGRESS: Basic information concerning the physical character, water use, water problems (including legal and economic) and water management of Michigan's watersheds is being collected for a comprehensive reference report. The proposed report will provide background data for current and developing watershed programs in Michigan.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Agriculture

2.1856, A SURVEY OF ATTITUDES TOWARDS THE MISSISSIPPI RIVER AS A TOTAL RESOURCE IN MINNESOTA
J.P. LUDWIG, Bemidji State College, Undergraduate School, *Bemidji, Minnesota* 56601

This project will concentrate specifically on the upper Mississippi River from the Iowa border to its source in northern Minnesota. It is a joint project of natural scientists and social and behavioral scientists at the three Minnesota State Colleges--Bemidji, St. Cloud, and Winona- which are located in the river's valley. Researchers in the various involved disciplines will gather, evaluate, and collate existing data using modern tools, such as the computer, to provide a basic framework concerning the present state of man's attitudes toward and knowledge of one immediate natural resource, the Mississippi River. The proposed project will foster a cooperative inter-institutional, inter-agency, and inter-disciplinary study, providing a sound basis for future planning in such areas as additional scientific study of river ecology if necessary, and possible recovery programs. The project will also work toward much needed public information and education programs. Relevant findings will be disseminated through the news media, workshops, seminars, educational programs, and publication in appropriate journals.

Base line data will be collected on population, land use, statutes and ordinances. An attitudinal survey will be conducted which will gather information relating to attitudes toward use of the Mississippi River and regultory anti-pollution programs.

Findings will be used as a basis for educational programs designed to raise the general educational level and promote more positive attitudes toward intelligent use of water resources.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1857, SOCIAL ECONOMIC FACTORS IN THE ADOPTION BY INDUSTRY OF WATER POLLUTION CONTROL MEASURES
R.E. RICKSON, Univ. of Minnesota, School of Liberal Arts, *Minneapolis, Minnesota* 55455

This research will consider certain sociological variables involved in the adoption by industry of the technology associated with water pollution control in Minnesota. The variance in compliance with innovations in water pollution control between and within categories of industries will be studied. Managers of heavy water using industries and governmental officials will be interviewed; appropriate statistical tests will be made to analyze the interview data. The increased use of water in Minnesota has resulted in increased pollution. Some changes in the behavior of users toward water pollution control is, therefore, an urgent necessity. The results of this research control should improve the understanding of the social dimensions of the problem and provide valuable information concerning the process by which change occurs or is resisted.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1858, METHODOLOGY FOR INTEGRATING WATER QUALITY MANAGEMENT WITH THE MANAGEMENT OF THE TOTAL WATER RESOURCES IN MINNESOTA
C.P. STRAUB, Univ. of Minnesota, School of Public Health, *Minneapolis, Minnesota* 55455

This research is aimed at studying the water quality problems associated with the many existing and possible uses of the water resources of Minnesota and proposing methodology for integrating water quality management with the management of the other aspects of the resource. The investigations will include: collection of data on water quality for the total resource, both surface and groundwater, in Minnesota; and a study of these data: a) to determine water quality parameters to be incorporated in future programs of data collection and analysis and b) to propose methodology for integrating quality management with that of the total resource, bearing in mind likely uses of the resource.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1859, PUBLIC INVESTMENTS IN NATURAL RESOURCES
L.R. MARTIN, Univ. of Minnesota, Agricultural Experiment Sta., *Saint Paul, Minnesota* 55101 (MIN-14-087)

OBJECTIVE: Improve investments in natural resources in Minnesota for such purposes as parks, recreation and wildlife, water developments, land improvements, drainage, flood control, waste disposal, and forestry.

APPROACH: The first part will involve an inventory and categorization of natural resource expenditures by various resource districts and other governmental units from secondary sources. The second part of the project will involve an evaluation of organizational and operational characteristics of selected existing and proposed districts. The third part, will develop suggestions for decision making by districts.

PROGRESS: The analytical work in Phases II and III is complete and that in Phase IV is largely complete. Most of the descriptions and analyses in Phases II and III are in first draft, including the in-depth analysis of three small watersheds and the over-all analysis of ten other small watersheds. What remains to be done is to complete the analyses in Phase IV, work out their economic interpretations, and write up the results. All of these efforts are now in process.

SUPPORTED BY Minnesota State Government - Saint Paul

2.1860, ECONOMICS OF WATER QUALITY CONTROL IN THE UPPER MISSISSIPPI RIVER (MINNESOTA)
J.J. WAELTI, Univ. of Minnesota, School of Agriculture, *Saint Paul, Minnesota* 55101

Objectives: The overall objective of the project is to formulate an economic optimizing model for water quality control and sewage disposal on selected stretches of the upper Mississippi River. The model will be designed to serve as a useful basis for public policy decisions in Minnesota with respect to both the water quality standards adopted on particular segments of the River and for least-cost-methods of attaining given standards. The methodology developed would be expected to be adaptable to water quality problems elsewhere.

Specifically, the model would be useful in answering such questions as: 1. What is the least-cost strategy of attaining given water quality parameters, taking into account: a. Natural assimilative capacity of the river; b. Variations in flow; c. Alternative levels of treatment; d. Alternative locations of treatment; 2. What are the economic benefits associated with alternative standards, taking into account the above? 3. What are the costs and benefits associated with raising or lowering water quality standards on particular stretches of the river? 4. What are the policy implications for stream standards versus uniform effluent standards for all waste dischargers?

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1861, ECONOMICS OF SEDIMENT CONTROL ON A MIXED WATERSHED IN NORTH MISSISSIPPI
H.P. COSPER, U.S. Dept. of Agriculture, Sedimentation Laboratory, *Oxford, Mississippi* 38655 (NRE2-25-25-04)

OBJECTIVE: Analyze costs and benefits of alternative means for reducing sediment yields by combinations of land treatment and structures.

APPROACH: Estimate economic effects of different levels of sediment management, based upon physical relationships for predicting sediment yields associated with alternative land use and watershed management schemes as developed by or in association with the Agricultural Research Service.

PROGRESS:

SUPPORTED BY U.S. Dept. of Agriculture

2.1862, MISSISSIPPI'S WATER LAWS AND POTENTIAL DEVELOPMENT PROBLEMS
J.E. WALDROP, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39752 (MIS-3-206-0258)

OBJECTIVE: Describe Mississippi's water laws, its ownership, use rights, the procedures for obtaining legal rights to use water, the adequacy of the current statutes under shortage situations. Evaluate some of the economic implications of Mississippi's water laws.

APPROACH: The statutes of Mississippi will be searched. Problems that might be posed to test the adequacy of these laws in terms of economic implications include agricultural vs. industrial use of water, polution from erosion, irrigation, industrial effluent and garbage disposal.

PROGRESS. Very little progress has been made on this project for two major reasons. First, the project leader with primary responsibility for legal aspects of this project at the University of Mississippi resigned from the institute and has not been replaced and secondly, the death of Walter Christ hampered the efforts of the institute during 1969. Hopefully, these problems are partially solved at this time, and it is anticipated that revision of a rough draft of Mississippi's water laws will be continued and a report published during 1970.

SUPPORTED BY U.S Dept. of Agriculture

2.1863, ENVIRONMENTAL PLANNING ALONG MONTANA'S 'BLUE-RIBBON' TROUT STREAMS
S.S. FRISSELL, Univ. of Montana, School of Forestry, *Missoula, Montana* 59801

To insure maintenance of a quality environment along outstanding waterways, study is needed of: 1) the current land use practices adjacent to the streams, 2) the impact of these practices on the stream environment, 3) the ability of the state to protect these streams under existing policies, and 4) the need for new guidelines and authority to insure protection.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1864, ECONOMIC IMPACTS OF WATER POLLUTION CONTROL PROGRAMS ON CATTLE FEEDLOTS
M. BAKER, Nebraska Agric. Expt. Station, *Lincoln, Nebraska* 68503 (NRE8-2-28-01-X1)

OBJECTIVE: Assess the economic effects of water pollution from feedlots; evaluate alternative means of pollution abatement; estimate potential economic impacts on the feedlot enterprise, local community, and beef feeding industry from implementation of water quality regulations.

APPROACH: Select a case study watershed with feedlots. Define water pollution from feedlots. Determine existence and severity of damages to water users. Estimate costs to feedlot firms of alternative means of controlling water pollution for various types of feedlots. Estimate the potential economic costs and benefits from water quality regulations for the case study area in terms of the feedlot firms, local community, and the beef feeding industry.

PROGRESS:

SUPPORTED BY U.S. Dept. of Agriculture

2.1865, COORDINATING THE EFFORTS OF PARTICIPATING AGENCIES IN A STUDY OF ENVIRONMENTAL EFFECTS OF WARM-WATER DISCHARGES INTO THE MISSOURI RIVER
E.R. KENDLE, State Game & Parks Commission, *Lincoln, Nebraska* 68509

Objective: To provide overall coordination for all (fishery, chemistry and physics and fish-food organisms) portions of the comprehensive study to be carried out by the various agencies involved: Bureau of Sport Fisheries and Wildlife, Federal Water Quality Administration, Iowa Conservation Commission, Nebraska Department of Health, Nebraska Game and Parks Commission, U. S. Army Corps of Engineers, U.S. Geological Survey, University of Nebraska.

Procedures: 1. Establish a schedule of operation for the field and laboratory work. 2. Insure that all agencies learn of any changes in the schedule of operation. 3. Act as a coordinator among personnel doing fishery, chemistry and physics and fish-food organism portions. 4. Insure that sufficient personnel and equipment are scheduled at the proper time to accomplish the field and laboratory work. 5. Preside at all meetings. 6. Preparation of study reports and distribution to all involved agencies.

SUPPORTED BY U.S. Dept of Interior - Bu. Sport Fish.

2.1866, EFFECT OF WATER MANAGEMENT ON QUALITY OF GROUND WATER AND SURFACE RECHARGE IN LAS VEGAS VALLEY
A.E. PECKHAM, Univ. of Nevada, Desert Research Institute, *Las Vegas, Nevada* 89109

A description of project objectives and proposed work are as follows: 1) To identify the effects on water quality of current water and waste water management. 2) To develop a comprehensive set of alternative solutions to the water quality problems which now exist as a result of the discharge of poor quality ground water in Las Vegas Wash and elsewhere in the lower portions of the Las Vegas Valley. 3) To demonstrate which of the possible solutions can most effectively be implemented to correct the pollutional aspects of Las Vegas Valley ground water and aid in general environmental quality improvement. 4) To demonstrate how waste water can be managed in such a manner as to improve the quality of the water which discharges into Lake Mead. 5) To develop a model of the system utilizing information developed from the Bureau of Reclamation project 13030 EII.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1867, USER ATTITUDES TOWARD WATER QUALITY AND PRICE
D.D. FOWLER, Univ. of Nevada, Desert Research Institute, *Reno, Nevada* 89507

This research will determine the feasibility of a large-scale survey of user attitudes toward water quality in the Las Vegas Valley and Reno-Sparks, Nevada by means of a pilot project to develop and pretest the questionnaire to be used in a subsequent survey.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1868, NEW HAMPSHIRE-TOMORROW - A COOPERATIVE EFFORT TO INITIATE ENVIRONMENTAL DEMONSTRATION PROJECTS & CREATE AWARENESS OF PROBLEM
R.D. SHEAFF, New Hampshire Charitable Fund, *Concord, New Hampshire*

Five Action Teams, each consisting of representatives of business, labor, civic groups, state agencies and local governments, have been established: Economic Growth and the Environment, Pollution Control, Scenery Preservation, Acquisition and Access, Environmental Education. Over 40 specific projects are being carried out under these categories, including: establishment of a local community recreational park, introduction of environmental topics into elementary and college curricula; study of sedimentation problems accompanying land sub- division; establishment of a multi-community open pit incinerator for solid waste disposal; testing of dye kits to identify water pollution; control of eutrophication through stratification; spray irrigation; design of industrial parks; junk car removal; visual inventory of New Hampshire's seacoast; scenic rehabilitation and preservation of a highway; establishment of the legal ownership of the state's islands; creation of a regional environmental study area in conjunction with public and private school programs; mobile homes park design; establishment of land trusts; securing of easements; establishment of community conservations; creation of lake association.

Prior to the termination of the program in the Spring of 1971, 'How-To-Do-It' booklets developed as a result of these specific field experiences will be printed and made available to existing agencies. These can serve as guidelines for future efforts.

2. WATER QUALITY

SUPPORTED BY Ford Foundation - New York, N.Y.

2.1869, A COMPENDIUM OF WATER LAW AND ECONOMICS IN NEW HAMPSHIRE
R.H. FORSTE, Univ. of New Hampshire, School of Agriculture, *Durham, New Hampshire* 03824

The considerable body of statutory and common law relating to water rights in New Hampshire exists in a diffused form throughout state statutes and in court decisions over a period of more than 150 years. Some of these statutes and decisions have relevance to wate law and use today; other statutes and laws that have been in effect for over a century may impose adverse effects on the economic efficiency of water use and the distribution of income associated with particular water users. The objectives of this study, therefore, are: (1) to describe relevant existing statutory and common law as it relates to water resources in New Hampshire; and (2) to assess the economic effects of these laws on water users and use patterns in qualitative terms, in areas of water quality, diversion, accessibility, multiple -use, and so forth.

Legal research is being performed mainly at the law offices of Alexander J. Kalinski, 51 High Street, Manchester, New Hampshire.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1870, SURFACE AND GROUND WATER POTENTIALITIES OF THE MULLICA RIVER BASIN
M.L. GRANSTROM, Rutgers the State University, School of Engineering, *New Brunswick, New Jersey* 08903

The proposed research p oject involves a systems analysis study and an ecological field investigation of aqueduct water transfer from the Mullica River Basin (containing a large state water reserve) to several New Jersey cities. This study will determine the: 1) cities which will have future demands for Mullica River water 2) optimum conjunctive surface and ground water development 3) economic effects of water withdrawal on shellfish, other biota, recreation, and waste assimilation capacity of the river and estuary.

The systems analysis approach will involve applications of extremal mathematics, such as linear programming, or simulation and stochastic processes. Fish spawning and nursery grounds studies and plankton dredging surveys will determine the distribution of these biota with respect to the existing and projected hydrography of the river-estuary system. Dissolved oxygen, salinity, and other water quality parameters will also be measured for the mathematical model. Project results will be applicable to other river basins which have conjunctive surface and ground water potentialities which affect the estuarine ecology.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1871, GOVERNMENTAL AND PRIVATE SERVICES
A.J. KAPLOVSKY, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00530)

OBJECTIVE: Provide services to governmental agencies, industries and individuals to help solve water supply, waste disposal, stream pollution and air pollution problems in cases where such services are not available from other sources, provide opportunity for faculty and students to experience practical problems and to determine research needs.

APPROACH: Study and make recommendations on problems brought to our attention and to make routine visits to state institutions to assess water supply, waste disposal or pollution situations which may lead to problems. Design assistance will be provided for systems as requested.

PROGRESS: 22 of 34 state institutions and agencies were given service. Watershed surveys and efficiency analyses were made with general assistance and operational maintenance problems consultation. Special added attention was required for 4 areas namely Leesburg, Trenton State Farm, Greystone Park and Annandale. Cooperative program of sampling of surface and ground waters for phenol was continued with U.S. Geological Survey. Phenolic concentrations in excess of 1.0 mg/l were found. A more sensitive procedure showed more phenol in 25.4% of 307 samples taken than by less sensitive method. Separation of CO(2) from water and ammonia in wastewater investigated by hollow fiber membranes. Effects of pH, concentration, pressure, and temperature on the ammonia separation was studied. Study was made to determine fundamental mechanisms by which non-electrotype solutes are rejected by reverse osmosis membranes. The overall approach used was to compare rejection of various selected compounds in dilute aqueous solution under typical operating conditions.

2.1872, ADAPTIVE CONTROL THEORY APPLIED IN A CLASS OF DYNAMIC POLLUTION PROBLEMS
H.J. PERLIS, Found. for Adv. of Grad. Study, *Newark, New Jersey* 07103

This research program is concerned with the application of the techniques of passive and active adaptation to a specific class of distributed parameter systems found in the area of water pollution. The overall objective is to provide a self-adjusting pollution control system which responds to effluent inputs and parameter variations. Specifically, the specialties of automatic control theory and measurement theory will be fully utilized in the course of the research. It is anticipated that the results of this work would be sufficiently general to find application in other environmental systems and in such distributed systems as biosystems and process control systems.

SUPPORTED BY U.S. National Science Foundation

2.1873, DELAWARE ESTUARY AND BAY WATER QUALITY SAMPLING AND MATHEMATICAL MODELING PROJECT
R.C. TORTORIELLO, Delaware River Basin Comm., *Trenton, New Jersey*

The objectives of the demonstration grant project are to establish a definitive sampling program to measure estuarine water quality to provide a baseline against which water quality improvement, as a result of a pollution abatement program, could be compared. In addition, the dissolved oxygen steady-state mathematical model of the Delaware Estuary would be verified against 1967 and 1968 observed boat run data. Comparisons would be made between compiled and historical data for trends or significant changes.

SUPPORTED BY Delaware River Basin Comm. - Washington

2.1874, ESTIMATION OF CAPITAL-WATER ELASTICITIES OF SUBSTITUTION IN U.S. MANUFACTURING
F.L. BROWN, Univ. of New Mexico, Graduate School, *Albuquerque, New Mexico* 87106

Five major determinants of the future levels of manufacturing water utilization are: 1) industrial output levels, 2) the degree of substitutability between capital investment and water, 3) technological change that influences water requirement per unit of product, 4) institutional controls and changes in the cost of water compared to cost of water substitutes, and 5) the proportions of industrial water intake utilized for cooling, and for processing.

Thus far, projections of the future industrial water requirements have been based almost solely on considerations of industrial output, with recognition, but little analysis, of the impact of substitution, technological change, or changes in relative costs. Without explicit analyses of the degree of substitution between capital and water loss, it seems likely that all forecasts of the future water needs for manufacturing are bound to contain significant errors.

The objective of this proposed project is the estimation and analysis of the degree of substitutability between capital and water in manufacturing. The procedural steps to be followed may be broadly categorized as: 1) the development from the available data of reliable estimates of capital investment, water losses, water recirculation rates, and output classified according to water resource region, state (when possible) and SIC industry; 2)

econometric analysis of alternative mathematical formulations of manufacturing productions functions leading to statistically reliable estimates of the elasticities of substitution in manufacturing between water and capital in the various regions and industries; 3) the interpretation of the results of 2) with respect to the formulation of suggested policy implications for such problems as deriving efficient pollution abatement and water transfer policies.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1875, UNITED STATES INDIA EXCHANGE OF SCIENTISTS AND ENGINEERS PROGRAMME
F. COULSTON, Unknown Inst. Or Indiv. Grant, *New York*

Dr. Frederick Coulston, Professor and Director, Institute of Experimental Pathology and Toxicology at the Albany Medical College of Union University in Albany, New York, has been selected to participate in the United States India exchange of scientists and engineers program.

Dr. Coulston will spend about one month visiting several medical institutes to give a series of lectures and seminars which outline and present the kind of basic research that is needed in Toxicology and Pathology for the protection of the community from unwarranted risk with chemicals and drugs taken voluntarily or involuntarily in air, water and food.

SUPPORTED BY U.S. National Science Foundation

2.1876, LAKE ONTARIO INTERIM COMPREHENSIVE FISHERIES MANAGEMENT PLAN
T.M. JOLLIFF, State Dept. of Env. Conserv., *Cape Vincent, New York*

Objectives: To continue development of an interim comprehensive fisheries management plan for Lake Ontario, to serve as a baseline or guideline for research and management activities.

Procedures: Planning will continue the work of the period January 1, 1971 thru March 31, 1971. The comprehensive plan will encompass historical factors such as the former abundance of fisheries, their decline, the deterioration of the environment, present problems, and managerial and research methods needed to meet present and future challenges.

The comprehensive plan will serve as a tool for the enhancement of both commercial and sport fisheries and related or associated activities. Factors which will be included in the overall plan are as follows: Development and management of previously abundant species of fish, management of present species, and introduction and management of new species. Environmental control involving pollution, water levels, etc., together with associated limnological studies all aimed at the preservation of fisheries and related activities. Compilation of catch and fishing effort statistics. Research on fish stocks, population dynamics and regulation of catch. Coordination of multi-agency activities, and computerization of inventory data. The place of fish culture in future fishery management in Lake Ontario. Special pesticide studies to permit utilization of fish flesh. Planning in terms of lake areas, geographical, estuarine, tributary, inshore and deep water factors, and population center locations.

Information will be taken from historical writings and the literature in general, available data on the lake, and previously written plans for Lake Ontario. Plans will be made in collaboration with other agencies, governmental and private, state, provincial and federal, educational and institutional.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1877, EVALUATION OF RECREATIONAL AND CULTURAL BENEFITS OF ESTUARINE USE IN AN URBAN SETTING
A.J. VANTASSEL, Hofstra University, Center for Bus. & Urban Res., *Hemstead, New York* 11550 (C-1818)

The proposed research plan involves field investigations to determine the extent of use of estuarine waters of the Town of Hempstead (located in an intensively urbanized area) as a basis for evaluating the benefits from such use. These surveys of use will be supplemented by studies of expenditures with local businesses by users. Data from both types of surveys will be subjected to economic and statistical analysis by investigators from the Hofstra University Center for Business and Urban Research.

Surveys of use will consider four phases: (1) Fishing, (2) Boating, (3) Clamming, (4) Nature Study. On the first of these, the Town of Hempstead has collected extensive data in considerable detail since 1966, and these data will be supplemented by similar data for 1969-1971. In addition, state and local governmental records will be supplemented by field investigations on other uses of Hempstead estuarine waters.

The data collected in these surveys will be subjected to economic analysis by the Hofstra investigators for the purpose of estimating the dollar value of benefits from use of the estuarine waters by type of activity and in total. This has importance in establishing the value of maintaining the estuarine waters in relatively unpolluted conditions.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1878, A STUDY OF POTENTIAL INSTITUTIONAL ARRANGEMENTS FOR WATER POLLUTION CONTROL IN THE HUDSON-MOHAWK RIVER BASIN
L.B. DWORSKY, Cornell University, School of Engineering, *Ithaca, New York* 14850 (C-1196)

Basin or sub-basin wide solutions to water pollution problems are technologically feasible considering existing technology and are possible conceptually using new and developing technology. Such solutions are expected to result in economies of scale, operational efficiency and the establishment of an improved priority basis for scheduling and pollutional control efforts.

A major obstacle to the development of basin or sub basin wide solutions has been the lack of modernization of governmental institutional arrangements to stimulate and encourage the early and efficient utilization of existing and newly developing technology for the public benefit.

The research proposes to develop alternative institutional arrangements for the Hudson-Mohawk River Basin, or appropriate sub-- basin units, to achieve a substantially improved water pollution control program for the study basin.

The plan of research will consider basin history, geography and culture; current water pollution control programs of state, federal, compact and local agencies; government organization affecting water pollution control; water pollution control plans; preliminary type engineering-economic studies of alternative pollution control measures; formulation of criteria to consider in the development of regional institutional arrangements for pollution control; the relation of alternative institutional arrangements for water pollution control to local water and waste water utility services, and to multi-basin and multi-purpose water and related land resources development programs in the northeastern United States. The research will conclude with a synthesis, recommendations and supporting references.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1879, STOCHASTIC MODELS FOR WATER RESOURCES MANAGEMENT
D.P. LOUCKS, Cornell University, School of Engineering, *Ithaca, New York* 14850 (C-1034)

Analytical methods are to be developed which incorporate the complex stochastic nature of streamflow and runoff into models for defining alternative policies for managing both the quantity and quality of water within a developed river system. The solutions of these stochastic programming models will indicate the daily reservoir releases and the quantities of water that should be allocated to each water use, so as to best achieve some physical or economic management objective and at the same time, satisfy all the requirements that are imposed upon the system. The study will begin in Fiscal Year 1968 and span a two-year period.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1880, CONSERVATION AND DEVELOPMENT PLANNING FOR THE ESTUARINE ZONE (A CASE STUDY IN THE TOWN OF SOUTHOLD, LONG ISLAND)
L.S. HAMILTON, State University of New York, School of Agriculture, *Ithaca, New York* 14850

2. WATER QUALITY

The estuarine zone, where fresh and salt water meet, is probably as rich in situations where one man's actions can inadvertently affect another man's welfare as any in the world of natural resources. Dredging, waste disposal, filling and bulkheading, silt and the like, can lay waste to the spawning grounds for fin fish, shellfish beds and areas of unique ecological significance. Important commercial, recreational and esthetic values can be quickly lost. Planning, controls and public investment decision processes have been developed to specifically solve these types of problems in other environments, but little has been done here. New institutions and approaches are required.

This project proposes to study the estuarine zone of an important part of Long Island in an attempt to identify the mechanisms by which problems arise, to determine the existing and potential roles of public agencies, and to develop an approach -- essentially a planning methodology -- suited to the evaluation of the public interest in the estuarine zone in meaningful policy and program terms. This project will seek positive means whereby local governments can both promote new economic development and still enjoy the fruits of this rich marine resource.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1881, MULTIPLE PURPOSE WATER RESOURCE INVESTIGATIONS

L.S. HAMILTON, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00126)

OBJECTIVE: Investigate critical multiple-use problems with respect to New York's surface waters, so that information is made available on which to base both private and public policy with respect to use and development of this vital resource.

APPROACH: Water-use conflicts are becoming increasingly severe even in the humid East. New York State already is experiencing conflict between irrigation, navigation, recreation, power production, pollution, municipal water supply, industrial use and flood control. Some of these conflicts will be examined as case studies with a goal of criteria for water allocation and policy formulation.

PROGRESS: Estuarine study has continued, with many of the portions of related projects completed, or nearing completion. Work on the Fall Creek Watershed has continued, and has served as background for interim reports. Three Ph.D. theses have been completed or drafted. Research in the Town of Southold has been completed. Research materials are being analyzed and prepared for thesis presentation for the Missouri River portion of the study and the small watershed planning study by Mr. Stern and Mr. Burgess. Field investigation and interviewing continues on the phase of the work concerning environmental planning and northeastern water resources institutions being carried out by Mr. Shelton.

SUPPORTED BY U.S. Dept. of Agriculture

2.1882, TELEVISION PROGRAMMING RELATED TO PROBLEMS OF THE ENVIRONMENT

R.D. HEFFNER, Columbia University, School of Education, *New York, New York* 10027

The Teachers College television study will include an analysis of the environmental implications of a representative slice of commercial broadcasting, an audience analysis, and an audience response study to determine what values have been transmitted by the programming. A panel of environmentalists will aid in the study.

Environmentalists believe that television is an important influence, for good or ill, on individual behavior toward the environment. However, they feel that much of the current programming is superficial, misleading, or self-serving and fails to draw implications between environmental pollution and individual behavior. For example, no connections are usually made between broad social problems, such as the effect of electric power production on the environment, and the individual behavior at the root of the problem, i.e., the demand for more and more power.

The study will be directed by Dr. Richard D. Heffner, an historian and communications analyst. The research design will be prepared by Dr. Robert Merton, Columbia sociologist. Results of the study will be made available to television producers and writers to help them in designing more positive programming.

SUPPORTED BY Ford Foundation - New York, N.Y.

2.1883, STOCHASTIC BASIS FOR COMPREHENSIVE RIVER BASIN PLANNING, PHASE II

F.G. HAAG, Union College & University, School of Engineering, *Schenectady, New York* 12308 (C-1702)

Systems analysis and stochastic methods will be utilized to model river basins. Wherever possible known probability frequency distributions wil be used with Monte Carlo methods. If probability frequency distributions do not exist they will be developed analytically and correlated with available data, as for example, in operational hydrology. The overall mathematical model for the physical variables of a river basin will be developed and programmed for the Union College digital computer. The results obtained when the model is applied to the Hudson River Basin will be compared against data that is available from New York State and the U. S. Geological Survey.

Economic data will be developed to permit relating the cost of alternate water development plans (e.g., waste treatment plants, flow augmentation, and water transmission facilities) to the relative economic benefits to alternate users (e.g., domestics, industrial, recreational, commercial fishing, and transportation).

The physical and economic models will be coupled and optimization techniques will be applied. The use of stochastic methods will permit more realistic decision making because the degree of chance taking will be described quantitatively in terms of confidence levels.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1884, STUDY OF INSTITUTIONAL ARRANGEMENTS FOR MANAGEMENT OF REGIONAL SEWERAGE PLANS FOR THE TOCKS ISLAND REGION OF THE DELAWARE

G.S. BIRKHEAD, Syracuse University, School of Public Affairs, *Syracuse, New York* 13210

Water Resources Planning (Institution Problems): This will be a study of alternative organizational means for implementing regional sewerage plans in the Tocks Island Region of the upper Delaware Basin. The researchers will examine the options for regional sewerage management currently included in the law in each of the three states in question. They will deal with: the present legal and fiscal options, the political situation and experience associated with these options and with the alternatives that may require new legislation or constitutional amendments. The final report will include: 1) a definition of the problem; 2) alternative structural possibilities, including local special districts or authorities, interlocal cooperation state special districts or authorities, direct state administration, interstate cooperation by compact, parallel laws, or DRBC and alternative management arrangements, 3) considerations of legal, political and fiscal feasibility; and 4) recommendations.

SUPPORTED BY Delaware River Basin Comm. - Washington

2.1885, ALLOCATION OF STREAM POLLUTION CARRYING CAPACITY

N.L. NEMEROW, Syracuse University, Graduate School, *Syracuse, New York* 13210

Can a river basin commission allocate in an equitable manner pollution carrying capacity among the many and varied users? Inherent in this question are many subsidiary matters which must be decided by the commission such as (1) in our social structure today do organizations exist as legal operating agencies which can assume the responsibility and task of allocating water pollution capacity and, if not, how does one go about forming and establishing such a commission? (2) will it decide to regulate by legislative and legal means the dwindling pollution-carrying of its basin or (3) will it be willing and able to establish a reasonable dollar value of each unit of resource and offer the units for purchase in an equitable manner.

It is our intent to use a simulation technique only during the final year of this project to study the reactions of a suitable com-

mission. All reactions will be on paper only and will not be publicized locally since they will neither have any legal basis nor be for the purpose of providing public information. The simulation study will be made solely to test the reactions of a suitable commission in policy-making situations. Information such as dollar benefits at various water quality levels as well as means for measuring water quality will be provided to the commission. The reactions of the commission will be of the utmost importance to the Federal Water Pollution Control Administration in developing policy and procedure for abating regional pollution. The project began in January 1967 and will terminate in June 1970.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1886, INSTITUTIONAL SEA GRANT SUPPORT
J.T. LYMAN, Univ. of North Carolina, School of Public Health, *Chapel Hill, North Carolina* 27514

The University System of North Carolina plans to undertake the difficult task of developing an integrated sea grant program involving the campuses at Chapel Hill, Raleigh, and Wilmington, and East Carolina at Greenville.

The research will include an attempt to culture dolphin fish in addition to defining the sport fishery for this species off the North Carolina coast. Sturgeon and striped bass will also be investigted as species for potential culture. Studies on optimum ecological designs for estuaries fertilized with sewage effluent, will be undertaken. Legal and economic studies will be directed to the compilation and analysis of the legal structure of the state as it affects marine resource development. Coastal research involving such activities as the determination of the optimum means of stabilizing spoil from channel dredgings, and insect infestation on stabilizing dune grasses will be pursued. A seafood program will be initiated with a study on utilization of scallop wastes. The Engineering Department will initiate a study on the reliability analysis and optimum design of marine structures. Extension courses and advisory services will be developed for upgrading North Carolina industry.

SUPPORTED BY U.S. National Science Foundation

2.1887, ENVIRONMENTAL CONSIDERATIONS IN LAND AND WATER USE PLANNING IN RIVER BASINS
J.E. WUENSCHER, Duke University, School of Forestry, *Durham, North Carolina* 27706

Objectives: To develop criteria for ecologically sound land and water use planning in river basins of the North Carolina Piedmont. This will include development of a land and water use suitability classification system to guide use and development of river basins without destroying the integrity of the river basin ecosystem.

To demonstrate the feasibility of ecological land use planning as a tool for determining the optimum patterns of development of river basins.

To evaluate the recreation and open space potential of the Eno River Basin as a wild-land corridor within an expanding urban area.

To develop a comprehensive plan for the ecologically sound future use of the Eno River Basin.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1888, MULTI-DISCIPLINARY RESEARCH IN POLLUTION
D.G. BARNES, Saint Andrews Presby. College, Undergraduate School, *Laurinburg, North Carolina* 28352

No summary has been provided to the Science Information Exchange.

SUPPORTED BY Research Corporation - New York, N.Y.

2.1889, MULTIPURPOSE REGIONAL MARINE SCIENCE CENTER (SEA LAB)
R.G. SOWERS, State Dept. of Conserv. & Dev., *Raleigh, North Carolina* 27611

The sea lab will be a multipurpose marine science center with each occupant of the center making significant contributions to the commercial fishing industry. The sea lab will serve to moderize the industry by putting the approach to the commercial fishing business on a more scientific basis. The building to be constructed will be a two story office-laboratory structure with the necessary accessory equipment needed for conducting diverse applied research activities involving sanitation, pollution, marketing, and product processing as well as aquaculture and other applied marine investigations that have a particular contribution to improving the commercial fishing industry.

Activities within the lab will involve seafood research and inspection management programs aimed at conserving the fisheries, economic and ecological position in the region's economy. Building scheduled for completion in September 1971.

SUPPORTED BY Coastal Plains Regional Commission

2.1890, COST-REDUCING TECHNIQUES OF WASTE DISPOSAL AND OPTIMUM USE OF WATER RESOURCES
W.M. CROSSWHITE, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC03215)

OBJECTIVE: Determine the pattern of water use by plant processes. Determine the origin, nature and quantity of polluting matter by major processes. Evaluate the impact of selected factors on water utilization and pollution. Compare the relative costs of prevention and control of waste within the plant and treatment.

APPROACH: The analysis will be divided into three segments: a review of literature; analysis of water use by major processes within selected plants and the factors influencing the generation of wastes; development of specific cost-reducing techniques for the most important processes and publication of findings. The analysis of individual processes will allow for comparisons to be made which will reflect differences in water use, pollution level and costs.

PROGRESS: A research, development and demonstration project, developed cooperatively with Gold Kist Poultry Division, Cotton Producers Association, was approved by the Federal Water Pollution Control Administration for the two-year period July 1, 1969, to June 30, 1971. The collection of benchmark data on water quantities and waste- water characteristics is approximately 50 percent complete. Preliminary budgets for selected process and equipment changes are being developed. A proposal entitled 'An Economic Study of Municipal Surcharges on Industrial Waste' has been submitted to the Office of Water Resources Research for support beginning July 1, 1970. The Water Resources Research Institute is supporting preliminary work for the remainder of fiscal 1970. A research, development and demonstration proposal for a study of Water and Waste Management in Sweet Potato Processing has been drafted and is under informal review by FWPCA.

SUPPORTED BY U.S. Dept. of Agriculture

2.1891, PUBLIC PARTICIPATION IN WATER POLLUTION CONTROL POLICY AND DECISION MAKING
D.S. HOWELLS, Univ. of North Carolina, Water Resources Research Inst., *Raleigh, North Carolina* 27607

1. To examine public perception of water pollution control issues, including character and dimensions of the problem; methods of control; ecological, economic and social implications; alternative choices; responsibility of regulatory authority and programs; community leadership attitudes; awareness of hearing schedules and sources of information. 2. To examine participation in public hearing and related procedures for the review of pollution control policy and stream classification in the State of North Carolina including individual and special interest group; intragroup participation in statement formulation; economic and social interests in pollution control; and areas of public interest not represented. 3. Recommendations for public education in water pollution and its control. 4. Recommendations for strengthening opportunities for public participation in development of water pollution control policy and decision making.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1892, ECONOMIC EVALUATION OF CHANGES IN LAND USE OF A MUNICIPAL WATERSHED AS A GUIDE TO DECISION-MAKING
T.E. MAKI, Univ. of North Carolina, Graduate School, *Raleigh, North Carolina* 27607

The proposed research involves two major phases, the first of which consists mainly of photogrammetric analysis of six sets of photos taken at varying intervals over a 30-year-period, supplemented by field investigations, to delineate the nature and extent of changes in land use over the past forty years on the 168-square mile Lake Michie municipal watershed near Durham, North Carolina. Concomitantly, the Lake Michie reservoir records would be examined and compiled to provide data on variation in yield, quality, and treatment costs of the water over the same 40-year period. The data on land use changes and on weather factors would comprise the variables against which the reservoir water records would be assessed and correlated by appropriate statistical techniques.

The second major phase consists of an appraisal of research results at several hydrologic stations where vegetative cover manipulation has been studied in relation to streamflow. Relevant treatments would be selected and applied hypothetically in kind and degree to cover types on the Lake Michie watershed after a detailed field investigation of the composition and condition of the existing vegetative cover of the watershed to determine what increases in streamflow might be effected through alternative treatments and what the net benefits from such treatments would be.

Finally, an attempt would be made to develop guides that would be helpful to managers of municipal watersheds in decision-making.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1893, ENGINEERING ANALYSIS OF WASTE TREATMENT
R. SMITH, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

Mathematical models have been developed to describe both the performance and cost for all of the conventional water renovation processes. The goal of this work is to optimize a system of water renovation processes to meet any specific need for water treatment at minimum cost. Computation is accomplished with digital computer.

Models for the advanced processes such as carbon adsorption and electrodialysis are being developed and will be combined with the models for conventional processes to study water reuse systems. Much information is still lacking, however, for the advanced processes. A secondary goal of the work is to lend continuity and guidance to the experimental programs underway in the Federal Water Pollution Control Administration. Work is also underway to improve the quality of the capital and operating cost relationships now being used.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1894, A SOCIO-ENVIRONMENTAL STUDY OF A RIVER VALLEY
M.R. ZAVON, Univ. of Cincinnati, School of Medicine, *Cincinnati, Ohio* 45221

This project will study the feasibility of establishing a long-term surveillance of the interactive effects of man and his environment in a single river valley complex. The Great Miami River Valley includes large cities, small towns and farmland. Animals and man living in the valley produce sanitary waste and the products of daily living; industries in the valley contribute heavily to the overall burden of waste which must disposed of by the air, the water, or put on the land. The people in this valley complex came from different geographical sources with differing cultural and social backgrounds. Their heritage predisposes them to certain ways of solving problems and to the organization of their social fabric.

The project represents an approach to research in which the social, biological, and physical sciences contribute data to a centralized facility. During the phase supported by the present grant, three individual research investigations will be carried out at the same time as the central project office will determine whether research conducted in this context may be done at less cost, more productively, and more meaningfully than similar research done without the unifying concept proposed.

SUPPORTED BY U.S. National Science Foundation

2.1895, COMMUNITY REACTIONS TO WATER RESOURCES PROBLEMS IN RELATION TO PLANNING
R.R. DYNES, Ohio State University, Graduate School, *Columbus, Ohio* 43210

The proposal views flooding, water pollution and depletion as different forms of objective collective stress. It is suggested here that those types of collective stress which develop over long periods of time are more difficult to perceive and, therefore, it becomes more difficult to initiate planning and action to cope with them. The study focuses on interviews with a sample of community decision makers in five different communities. The five communities will be selected on the basis of having experienced different types of collective stress. In each community, the definition of the salience of such problems for the community will be determined. In each community the types of adaptation in terms of planning and inaction will be determined. Various social factors will be related to the differential perceptions and adaptations of each community.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1896, PUBLIC INVESTMENT CRITERIA FOR WATER-ORIENTED RECREATION IN THE LAKE ERIE BASIN
R.A. TYBOUT, Ohio State University, Graduate School, *Columbus, Ohio* 43210

The project has three parts: 1) The measurement of demand for water-oriented recreation at numerous sites. 2) Analysis of costs of pollution abatement and recreation facilities at the same sites. 3) Evaluation of the relative merits of alternative public investments for recreation enhancement and of selected financial policies.

Each part is assigned a year of research time. Demand will be measured by a simultaneous-origin adaptation of the Hotelling-Clawson method. Shifts in demand due to pollution and income changes will be measured and, in fact, play an important part in the determination of benefits from abatement. The analysis of costs of pollution will seek to relate marginal pollution contributions at recreation sites to costs of abatement. The third, or final part of the analysis will explore the implications of combining the results of the first two parts in a cost- benefit framework with various methods of financing, including pollution taxes, user charges and other revenue sources.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1897, MATHEMATICAL AND COMPUTER SERVICES FOR THE ANALYSIS OF DATA AND DESIGN OF EXPERIMENTS FOR CERTAIN FWQA PROGRAMS
D.D. AUFENKAMP, Oregon State University, Computer Center, *Corvallis, Oregon* 97331

The Computer Center at Oregon State University is providing mathematical and computer services for the analysis of data and design of experiments for the following FWPCA programs: (1) fate of pollutants in coastal waters, (2) eutrophication, (3) power production, (4) paper and allied products, and (5) forestry and management.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1898, ECONOMIC BENEFITS FROM AN IMPROVEMENT IN WATER QUALITY
H.H. STOEVENER, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

This proposal is designed to study the value of water quality and water quality improvements in Upper Klamath Lake. It will

seek to estimate the benefits resulting from increased recreational use of the lake after technically feasible methods of retarding and/or reversing the eutrophic trends of the lake have been implemented.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1899, ECONOMIC EVALUATION OF WATER POLLUTION CONTROL
H.H. STOEVENER, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00550)

OBJECTIVE: Determine the economic benefits accruing to society from a postulated improvement in water quality through increased recreational use of Upper Klamath Lake, Oregon. Determine the economic benefits accruing to the Klamath County economy from the postulated water quality improvement.

APPROACH: Modification of the methods used by Clawson and others will be utilized to derive demand functions for outdoor recreation at Klamath Lake, given an improvement in water quality of the lake. The development of methodological improvements for deriving these demand estimates will be emphasized. Objective (2) will be accomplished by studying the structure of Klamath County economy through an input-output model and tracing out the secondary effects of the water quality improvement. Data are to be collected from recreationists and businessmen in Klamath County.

PROGRESS: Work continued on a final preparation of a manuscript describing the research on the Yaquina Bay case study. This was an interdisciplinary effort involving economics, biology, and engineering. It is anticipated the manuscript will be completed and published sometime during the next fiscal year.

SUPPORTED BY Oregon State Government

2.1900, ECONOMIC BENEFITS FROM AN IMPROVEMENT IN WATER QUALITY
H.H. STOEVENER, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

The research has the following principal objectives: 1. To determine the relationship between water quality and recreational use, permitting the prediction of the change in recreational use when a substantial improvement in water quality has been made in a large body of water. 2. To determine the economic benefits accruing to society from a postulated improvement in water quality and associated increase in recreational use determined under (1) above. 3. To determine the economic benefits accruing to the local economy in which the water resource is located from the postulated improvement in water quality and associated increase in recreational use.

The accomplishment of objectives 1 and 2 involves the development of a theoretical model to evaluate recreational benefits. Such a model is an extension of the techniques developed by Clawson and others. Water quality characteristics are to be included in the demand analysis to permit the empirical changes in recreational use and values. Interviewing techniques are used to collect data for the research. Recreationists are interviewed in the upper Klamath Lake area and a sample of other recreational sites in nearby regions.

To accomplish objective 3, an input-output model for the Klamath County economy resulting from an improvement in water quality in Klamath Lake and the associated increased use and expenditures made by recreationists. Data for this work are developed through interviews with business firms in Klamath County.

SUPPORTED BY U.S. Dept. of Agriculture

2.1901, APPRAISAL OF WATER MANAGEMENT INSTITUTIONS - SURVEY OF OREGON WATER LAW
O.D. CLARK, Univ. of Oregon, School of Law, *Eugene, Oregon* 97403

Object. 1. To conduct a survey study of Oregon water law. 2. To evaluate the adequacy of selected portions of Oregon water law, such as pollution controls. 3. To assess the vitality of common law principles expressed in early Oregon decisions. 4. To identify for further research legal problems of water resources management important to the Northwest.

Description of Work: Analysis will be made of Oregon court decisions, constitutional and statutory provisions, and Attorney General opinions regarding the use of the various water resources, surface and underground, of the state. This survey study will trace the historical development of Oregon water law, synthesize and evaluate existing Oregon water law, critically compare it with water law in other Western states, and otherwise seek to attain the objectives stated above.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1902, STATE WATER QUALITY MANAGEMENT INFORMATION SYSTEM
W.A. LYON, State Dept. of Health, *Harrisburg, Pennsylvania* 17120

To enhance and demonstrate a state-wide water quality management information system. The state has already done considerable work in this area. The purpose of the project is to expand the system and to provide a demonstration system which can be available for use by federal, other state and interstate water pollution control agencies. A further objective and purpose is to provide a base for a water quality management personnel. The design and implementation of this program will be the subject of an application (during the second year of this project) for a training grant under Section 5 of the Federal Water Pollution Control Act.

It is planned to: 1. Do the necessary systems design, programming and data processing so as to test, evaluate and demonstrate management information systems techniques related to the case status system, project status system, water quality control and forecasting system and plant operations control system. 2. Convert existing information handling techniques to modern EDP techniques. 3. Convert historical water quality data to a form useable by the system.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1903, THE INSTITUTE FOR THE DEVELOPMENT OF RIVERINE AND ESTUARINE SYSTEMS
J.R. FELDMEIER, Franklin Institute, *Philadelphia, Pennsylvania*

The Franklin Institute will establish, in cooperation with the Academy of Natural Sciences of the State of Pennsylvania, Lehigh University and Temple University, The Institute for the Development of Riverine and Estuarine Systems (IDRES). These institutions will conduct basic research programs focused on the long term objectives of better utilization of resources of the Delaware riverine-estuarine complex including effects of thermal pollution in the Delaware River, effects of thermal effluent discharge, the mechanics and thermodynamics of the distribution and mixing of thermal effluence, and the development of a conceptual model of sedimentation of the Delaware riverine-estuarine complex. In addition, an information center to serve the principal investigators conducting this research and as a focal point of coordination with other Federal and private information centers related to estuarine problems will be established by the Franklin Institute. Study and design of an industrial wasteline for the Delaware estuary with a view toward study of an alternative method to that now available for the disposal of waste will be begun.

SUPPORTED BY U.S. National Science Foundation

2.1904, ECONOMIC EVALUATION OF STREAM QUALITY PRESERVATION THROUGH URBAN LAND USE MANAGEMENT
R.E. COUGHLIN, Regional Science Res. Inst., *Philadelphia, Pennsylvania* 19104

Methods for evaluating the benefits and costs of preserving a major portion of a stream valley by conservation easements or similar land use controls for general water quality protection.

Development of mathematical statistical models to relate various urbanization parameters to channel size, flooding frequency and to basin water quality at base flow.

2. WATER QUALITY

Development of methods for determining the value of high water quality and high quality stream environments to residents using both subjective judgment data and land value data.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.1905, ECONOMICS OF WATER QUALITY IN A REGIONAL SYSTEM

W. ISARD, Univ. of Pennsylvania, Graduate School, *Philadelphia, Pennsylvania* 19101

Significance: Over the past several years, RFF has made considerable progress in furthering study of the economics of water quality management. In the early stages the staff and grant studies focused heavily upon clarification of concepts and empirical estimation of particular benefits and costs associated with improving water quality. Two books have already resulted from this effort and several other major reports are in preparation. In order to show the applicability and significance of the work already done, as well as to extend it, we have begun case studies of realistic situations characterized by differences in hydrology and in character and intensity of development. Two of these are under way dealing with the lower Potomac and the Miami tributary of the Ohio. The present study would be the third of the series. It would focus upon the Delaware Estuary. The estuary is heavily industrialized, has a large contiguous population and severe water quality problem.

Specific Aims and Expected Results: The project would use and improve existing tools for analyzing the water resources and economic development of the area. This would be done in order to assess the benefits and costs associated with alternative quality management programs. These might include such elements as regulation of river flows into the estuary, high-level treatment at certain times and locations, artificial re-aeration of the estuary, transporting wastes away from critical areas, and regulating reservoir system analysis, and forecasting of waste assimilative and transport capacities would be used in an integrated fashion. This would give new power and depth to water quality management analysis. The funds required to execute this study go beyond those which could be made available by RFF. Consequently the principal participants have worked out arrangements to obtain supplementary funds for certain of the natural service and engineering aspects of the work from the U. S. Public Health Service. It is expected that the project will result in several articles in professional journals and a publishable monograph.

SUPPORTED BY Resources for Future Inc. - Wash., D.C.

2.1906, STREAM QUALITY PRESERVATION THROUGH URBAN LAND USE MANAGEMENT - LEGAL AND GOVERNMENT ASPECTS

A.L. STRONG, Univ. of Pennsylvania, Graduate School, *Philadelphia, Pennsylvania* 19101

The Plan is a proposal for the wise use of the water and land resources of the Upper East Branch of Brandywine Creek, Chester Co., Pa. The Plan was developed for the Chester County Water Resources Authority by the Institute for Environmental Studies, University of Penna.; Regional Science Research Institute; United States Geological Survey; and their consultants. The aim of the Plan is to prevent deterioration of the water resources and thus to retain the amenities of related land when urbanization occurs in the Brandywine watershed. The Plan recommends 3 types of action: public purchase of conservation easements or other less than fee interests on flood plains, stream and swale buffers, steep slopes and forests; development and adoption of detailed water supply and sewage disposal plans in advance of urbanization; and enactment of strong local regulations for erosion and storm runoff control. Covers fiscal year 1/1/68 to 12/31/70.

SUPPORTED BY Ford Foundation - New York, N.Y.

2.1907, EFFECTS OF LAND USE CHANGES ON THE SCENIC QUALITIES OF PINE CREEK, PENNSYLVANIA

P.W. FLETCHER, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01842)

OBJECTIVE: Determine: flood plain's recent land use changes; nature, source, degree and extent of stream quality deterioration; flood plain's capability of providing potable water while accepting sewage wastes; and views of creek-front property owners on valley objectives, goals.

APPROACH: Trace recent flood plain changes from surveys of aerial photos, soils, and buildings; collect and analyze water quality samples along the main stream and on major tributaries; measure water percolation and groundwater movement rates of streambank soils; and conduct and analyze a mail opinionnaire and personal interviews.

PROGRESS: Preliminary water quality tests involving 17 criteria each were made at various day and night hours at weekly intervals throughout 15 summer weeks at 13 regular stations and several special points along 55 miles of Pine Creek and its major tributaries, using a Hach Direct Reading Engineer's Laboratory in conjunction with central laboratory facilities. Pollution was more pronounced in several headwaters stretches than in the lower stem. Paired dissolved oxygen tests in light and dark incubation were made twice at 4 headwaters locations at several points below 2 communities, one with primary treatment and one with secondary treatment. Special water tests were made below a farmland area and below a coal mine area. Preliminary tests indicated that the coarse, sandy streambank soils are capable of removing little of the nitrates and phosphates in effluents from septic tank sewage systems. An inventory was begun of the species of algae and aquatic vascular plants. A sample questionnaire was developed for securing facts and opinions from landowners along the stream.

SUPPORTED BY U.S. Dept. of Agriculture

2.1908, CRITERIA FOR DETERMINING ECONOMIC PRIORITIES IN AWARDING SEWAGE FACILITY CONSTRUCTION GRANTS

J.D. JANSMA, Penn. State University, Inst. for Res. on Land & Water, *University Park, Pennsylvania* 16802

The State of Pennsylvania uses a point system to determine relative needs in assigning priorities for awarding sewage facility construction grants. The relative needs considered are water pollution control (50 points), per capita costs (10 points) and financial need (40 points). The major objective of this research is to develop economic indices which measure financial need and per capita costs. Factor analysis will be the technique employed to group the various measures of a community's economic-well-being and thus provide the basis for the index of financial need. Alternative approaches for setting priorities will be evaluated in terms of economic efficiency and equity.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1909, SOCIO-ECONOMIC FACTORS RELATED TO THE INCIDENCE OF A WATER-BORNE DISEASE

G.C. UZDAVINI, Inter Amer. University, Undergraduate School, *San German, Puerto Rico* 00753

This study is to determine primarily the impact of Gastroenteritis, an illness caused by the water-borne enterobacteriaceae on the social and economic life in a community within the municipality of San German, Puerto Rico. Two areas within the community, one a public housing scheme and a slum area will be used to accomplish the following goals: (a) To determine the economic and social factors which lead to unsanitary conditions which enable enterobacteriaceae to develop and multiply, thereby causing an increase in the water contamination even though facilities are available; (b) To determine what the needs are that would alleviate this and other situations; (c) To mobilize the forces in the community to bring about changes in the physical and social environments which will diminish the incidence of this water carried organism and thereby create an atmosphere more conducive to physical health; (d) To develop a framework and background for further research in the area of the effects of water quality upon physical and mental health.

To accomplish these goals, the relevant sociological instruments and consequent analysis will be implemented.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1910, SOME LEGAL, SOCIAL AND ECONOMIC PROBLEMS OF GROUNDWATER POLLUTION
D.B. BURKE, Univ. of Rhode Island, Graduate School, *Kingston, Rhode Island* 02881

This is an interdisciplinary proposal involving principal investigators from the fields of planning law, sociology and economics. The objective is to suggest ways by which groundwater quality can be maintained at satisfactory levels, at least cost, through legal means.

The quality level considered satisfactory will be defined by an attitude survey of users to arrive at a concensus as to where contamination becomes objectionable in various uses. The least cost analysis will be undertaken by comparing the cost of protection of a groundwater supply by a sewage treatment plant to the cost of constructing a surface impoundment for a new supply. The cost of treatment of contaminated groundwater will be an alternative consideration. The laws relating to groundwater control for the public interest are at present vague and uncertain. Preservation of future supplies of groundwater is difficult if some of the water is not in current use. To make this protection easier is the main objective of the legal aspect of this study.

Information and data will be obtained by a survey of households in a local watershed, utilizing previous engineering studies of costs of new supplies as well as compiling cost estimates of other alternatives and by a study of the existing laws pertaining to groundwater control.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1911, SOCIO-ECONOMIC STUDY OF NARRAGANSETT BAY, RHODE ISLAND
N. RORHOLM, Univ. of Rhode Island, Agricultural Experiment Sta., *Kingston, Rhode Island* 02881 (RI00117)

OBJECTIVE: Identify, measure and evaluate the economic and social values of the marine resources of the Bay to the State of Rhode Island. The project will be based on secondary source information currently available to the University of Rhode Island with additional surveys or interviews being made as necessary to supplement existing data. Identify, measure and analyze economic and social trends in Rhode Island which would be significant in terms of water pollution control or land use regulation of the Bay and that portion of the watershed which is significant in determining the quality of estuarine water resources. Explore how benefit cost analysis techniques may be best applied to determine the effects of various conditions of beneficial uses on the estuarine resources. Identify and recommend needs for future studies or basic data systems which would be useful in obtaining optimum public benefits from use of the Bay resources.

APPROACH: Not Provided.

PROGRESS: First part of project has been completed. Work indicated that as much as $830 million economic activity was generated by Narragansett Bay, exclusive of general summer tourism, and without assigning values to recreational pursuits such as swimming, sports fishing, skin-diving, etc. or to the effect of the Bay on the quality of the environment. No doubt these values are considerable, but data of good quality with which to estimate their monetary impact is lacking. The $830 million activities generated resulted in $373 million in personal income. This was approx. 11% of the total personal income in the state in 1968.

SUPPORTED BY Rhode Island State Government

2.1912, USE OF ADVANCED WATER RESOURCES PLANNING TECHNIQUES IN THE DEVELOPMENT OF REGIONAL WATER MANAGEMENT PROGRAMS
B.C. DYSART, Clemson University, School of Engineering, *Clemson, South Carolina* 29631

The objectives of the research described in this proposal are as follows: (1) To construct mathematical models for the water quality response to pollutants of a river in an industrialized and developing basin of South Carolina, (2) To apply recent advances in operations research and system analysis techniques to the planning and management of the basin's water quality, (3) To develop alternative long-term water quality management policies for the basin which will enable continued industrial and urban growth as well as the protection of water quality for other beneficial uses of the resource, and (4) To demonstrate to state and local planning agencies the utility of modern management techniques as a guide to rational and orderly development and protection of the water resources of South Carolina.

The Reedy River basin in Greenville County, South Carolina has been selected for study in this investigation. Appropriate state, federal, and local agencies will be consulted to obtain information regarding goals and objectives of water resources development in the basin as well as hydrologic, waste production, and economic data. Alternative objective functions and constraint sets will be formulated. The mathematical system representation will be optimized using dynamic programming. The effects of various management approaches will be demonstrated.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1913, THE USE OF TAXES, SUBSIDIES, AND REGULATIONS TO CONTROL THE EFFLUENT OF THE TEXTILE INDUSTRY
H.H. MACAULAY, Clemson University, Graduate School, *Clemson, South Carolina* 29631

The purpose of the project will be to determine the differential effects of taxes, subsidies, and regulations on the use of water and the discharge of effluent by the textile industry. More specific objectives will be: 1. To estimate the economic values of nonmarket uses of water downstream from certain textile mills. 2. To determine the difference in economic results that stem from (a) regulations imposing higher stream standards, (b) a system of user charges or taxes, and (c) a system of subsidies. 3. To determine if a tax subsidy given at the local level (primarily by exemption from property taxes) differs in principle from a tax subsidy given at the national level (primarily by special deductions under the income tax). 4. To assess the difference in economic impact of higher stream standards on old mills and on new mills. 5. To estimate how the cost of cleaning up the effluent from the textile industry may affect the methods of processing textiles or lead to the development of new technology.

A theoretical model to provide for the optimum use of the resource will be constructed. An attempt will then be made to gather data which will make it possible to apply the model to the textile industry. Assumptions as to differences in taxes, subsidies, and regulations will be made to see how the use of water and the operation of the textile industry are changed by each of these conditions.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1914, ECONOMIC EFFECTS OF SUBSIDIES FOR POLLUTION ABATEMENT
H.H. MACAULAY, Clemson University, School of Management, *Clemson, South Carolina* 29631

Businessmen and lawmakers have by a large majority expressed a preference for subsidies to reduce stream pollution, while economists have by an equally large majority preferred effluent charges. The latter have been analyzed by those supporting them, but the former have been subjected to little economic analysis. This study seeks to determine: 1) the forms of subsidies that have been proposed by different levels of government for this purpose; 2) the economic validity of arguments advanced in support of subsidies, e.g. is waste abatement equipment 'nonproductive?' 3) the expected economic effects from different subsidies as these effects apply to: a) the change in the quantity of waste discharge by the firm and by the industry; b) the change in the revenue or expenditure of the governmental unit granting the subsidy, c) the incidence of the cost of and the gain from the subsidy.

Results will be sought by the application of price theory to data on methods and costs of waste treatment in certain industries. Data will also be sought from various governmental units granting subsidies.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1915, ADMINISTRATIVE LAW, PROBLEMS AND POTENTIALS, IN WATER RESOURCES (PHASE 2) PLANNING FOR SOUTH CAROLINA
C.H. RANDALL, Univ. of South Carolina, School of Law, *Columbia, South Carolina* 29208

The proposed research plan involves analysis of problems and potentials of administrative law and administrative agencies as tools to control environmental quality and allocation of water resources. The investigation will embrace analysis of present and potential law of South Carolina, the City of Columbia, and pertinent federal law. Conferences with personnel in those levels of government, and analysis of specific regulatory proceedings conducted by them, will be undertaken.

Proposals for advancing the law of South Carolina in resource and environmental control, both present law and proposed, have invariably looked to administrative law as the organizational approach. Problems of the respective functions of the agency, the Attorney General, and federal authorities, as well as problems of the adequacy of representation of all interests, including conservation, recreation and ecological interests, arise, as do problems of the fairness of hearings. Possibilities of such approaches as stream zoning, and the legal and consitutional problems raised thereby, will be studied.

Emphasis in conferences with agencies and study of particular proceedings will be given to the office of the Attorney General, the Water Resources Commission and represented agencies therein, including the Pollution Control Authority. Proposals for strengthening the law and the methods of procedure in allocation and enforcement proceedings will be submitted.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1916, URBAN WATER POLICY AS AN INPUT IN URBAN GROWTH POLICY
K.B. KENNEY, Univ. of Tennessee, Graduate School, *Knoxville, Tennessee* 37916

The proposed research project will examine the existing and potential use of urban water and sewer extension policy to guide urban growth. The objective will be to prepare guidelines and recommendations for the use of water and sewer extension policy to foster a more pleasant, efficient, and healthful urban development pattern. This will be done through an examination and comparative analysis of present urban water and sewer extension policies and related public policies in two or more urban areas.

Information will be obtained through a literature search, correspondence, and visits to selected cities for data gathering and personal interviews. Reports on two or more selected urban areas will examine and evaluate their water and sewer extension policy in detail, giving consideration to the environment and constraints under which it is operative, and assessing its apparent impact on urban growth patterns. This information will then be used to develop guidelines and recommendations and perhaps suggest new and innovative policy directions.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1917, THE ENVIRONMENT AND TECHNOLOGICAL ASSESSMENT
J.L. LIVERMAN, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831

The Oak Ridge National Laboratory will move toward a deeper involvement in the problems of the human environment. The institution believes that three steps are necessary: (1) expansion of some specific technical R & D activities that have immediate relevance to man, (2) establishment of ORNL in the broad scope of R & D disciplinary areas necessary for effective participation in the whole spectrum of environmental problems, and (3) development of activities in environment information and communications as needed and to size commensurate with the need. In order to initiate the three steps eight projects are proposed.

In order to expand specific technical R & D activities that have immediate relevance to man, Oak Ridge proposes three projects entitled: (1) Environmental Mutagenesis Program, (2) Techniques for Measuring Mutations Rate in Man, and (3) Water Treatment by Hyperfiltration with Dynamically Formed Membranes and Related Methods.

In order to establish ORNL in the broad scope of disciplinary areas of R & D necessary for effective participation in the whole spectrum of environmental problems, Oak Ridge proposes three projects entitled: (1) Programmatic Perception and Planning, (2) Case Study for National Systems Analysis: Technological Problems and Policy Alternatives for Stationary Power Plants, and (3) Regional Modeling, Environmental Systems Analysis and Public Policy. The development of activities in environment information and communications involves two projects entitled: (1) Environmental Information System and (2) Communication and Public Education.

SUPPORTED BY U.S. National Science Foundation

2.1918, WATER RESOURCES STUDY BY TEXAS WATER RESOURCES COMMITTEE
S. HAYNIE, State Legislative Council, *Austin, Texas* 78711

The 61st Legislature by enactment of H.C.R. 12 created the Texas Water Resources Study Committee to consider various facets of statewide water planning. Among specific areas being considered by the committee are: (1) the water situation in the state and the federal and state proposals concerning it; (2) changes in state statutes which are needed for water protection and development; (3) organizational structure of state water agencies and administration of state water law; (4) ecological effects should Texas Water Plan be implemented; (5) alternative methods of financing Texas Water Plan; and (6) review of water legislation enacted by the 61st Legislature (1969).

Committee will submit a written report and copies of proposed legislation to the 62nd Legislature in January, 1971.

SUPPORTED BY Texas State Government - Austin

2.1919, COMMITTEE FOR THE STUDY OF LAND USE AND ENVIRONMENTAL CONTROL
C. COLE, State Senate, *Austin, Texas* 78711

The 61st Legislature by enactment of Senate Concurrent Resolution 46 continued the Committee for the Study of Land Use and Environmental Control. Although this committee has studied and is studying all facets of the environment, one of its major concerns has been and is the study of water quality. Almost all of the water quality law of Texas was developed by this committee, and, at present, the committee is making further studies of water quality problems as a prelude to further legislation. The committee will submit a report and proposed legislation to the 62nd Legislature in January, 1971.

SUPPORTED BY Texas State Government - Austin

2.1920, ALTERNATIVE DEVELOPMENT PATTERNS, PLANS, CONTROLS AND IMPACT ASSOCIATED WITH NEW RESERVOIRS
F.W. SUGGITT, Texas A & M University System, Graduate School, *College Station, Texas* 77843

Investigation: Develop an 'ideal' plan based upon optimum utilization of the lake, the shore and the backland. This will assume that ways and means are available whereby such an optimum utilization of the resources can be obtained, to provide a maximum of recreation- residence-business satisfaction to the people of the local area, to absentee owners, and to visitors. Evaluation of implications: Develop a 'probable' development plan showing what would likely be attained without overall comprehensive planning and control, based upon whatever controls and guidance is now available, and transferring developmental history from other comparable lake situations. Evaluation of the ultimate costs, benefits, problems. Develop a 'practical' development plan that appears to be likely to be achieved with the installation of planning procedures and control. Evaluation of costs, benefits, deficiencies and problems. Procedure organization and

function of a Lake Livingston area regional planning commission, or council of governments, or development authority. Analysis of statutes, legal procedures, organization, finances, and operation of one or several instrumentalities. Measures needed to adopt and enforce ordinances and codes relating to land use, subdivisions, water supply, waste disposal, traffic control, (land and water), building and related codes. Steps needed to assure public understanding of recommended plans and organizations and ordinances. Evaluation of additional studies and efforts needed. Evaluation of additional sources of funds for such studies.

SUPPORTED BY Texas A. & M. University System

2.1921, ECONOMIC ANALYSIS OF ENVIRONMENTAL QUALITY EFFECTS ASSOCIATED WITH SEASONAL HOMES
M. BEVINS, Univ. of Vermont, Agricultural Experiment Sta., *Burlington, Vermont* 05401 (VT00197)

OBJECTIVE: Determine the environmental situations (positive and negative) associated with seasonal homes and analyze the attitudes, interests, and goals of people for a quality seasonal home environment.

APPROACH: Representative seasonal home communities will be chosen for study. Standard questionnaire will be developed and utilized. Interviews with public officials concerning water pollution and health hazards of seasonal home communities. Interview permanent residents and seasonal home owners to identify positive and negative effects of seasonal home communities.

PROGRESS: The first six months since project activation have been spent on problem delineation. Seasonal homes have both positive and negative effects upon environmental quality of a state or region. This is clearly recognized by top governmental officials and has led, in the State of Vermont, to the adoption of a new set of health regulations relating to land subdivisions. The need for research is pronounced at this point. Pollution caused by sewage effluent is the source of the major negative impact upon the environment. Research work is underway to make an economic evaluation of alternative means of handling sewage in seasonal home communities. Plans are underway for an intensive case study of a lakeshore community in Vermont where the negative environmental impact has been very great. Similar case studies will be made in other Northeastern States following a comparable format.

SUPPORTED BY U.S. Dept. of Agriculture

2.1922, ATTITUDES, OPINIONS AND GOALS CONCERNING REGIONAL RESOURCE PLANNING AND DEVELOPMENT
E.H. TOMPKINS, Univ. of Vermont, Agricultural Experiment Sta., *Burlington, Vermont* 05401 (VT00162)

OBJECTIVE: Determine attitudes of Vermont residents toward alternative goals of regional resource planning and development. Assist local and regional planning and development groups to conduct surveys of attitudes concerning alternative goals in their community or area. Determine goals or policy objectives of state and federal resource development agencies.

APPROACH: Surveys will be conducted in cooperation with regional and local groups which have been formed for the purpose of economic or resource planning and development. A core of questions will be used with additional questions at the option of the group concerned. Local assistance will be utilized as much as possible in conducting the survey. Two methods will be utilized. These will consist of mail surveys, and surveys administered to individuals attending group meetings. Information will be punched on cards for machine tabulation. Data from the surveys will be analyzed by the project leader. A report will be published for each survey conducted.

PROGRESS: An attitude survey of residents of the Washington County area was completed during the summer. This area has two planning regions--the Central Vermont Region and the Mad River Valley Region. A fourth partial report has been prepared on the findings from the Chittenden County Natural Resource Attitudes survey. Raw data have been made available to the Bennington County Regional Planning Commission. The final report on the Franklin County survey has been published. The survey shows that a majority of Franklin County residents want the following: a program for beautifying the county, new industries, stream pollution control, regional schools, better cooperation among towns, and more playgrounds. Findings from these studies are being used by local and regional planning and development commissions, state agencies, the Vermont Extension Service, and community improvement groups.

SUPPORTED BY U.S. Dept. of Agriculture

2.1923, PROGRAM PLANNING ON ACTIVITIES OF AGENCIES OF CONCERN TO PUBLIC WATERS
L.C. HALNON, State Fish & Game Department, *Montpelier, Vermont* 05602

Objectives: To participate in hearings, public meetings and on- site inspection of planned or proposed activities of state or federal agencies, or private enterprised which would directly affect the natural quality of the public waters of the state as they now exist. The object of the job is to be informed of any planned alterations of any agency, to prepare documentation as to the probable effect on public waters, and to participate in any meetings, public hearings or on-site inspection of proposed activities affecting fisheries management of the waters of the state.

Procedures: Project personnel will plan to attend meetings and hearings on proposals by other state agencies, Federal agencies, public utilities or other agencies as matters affecting fisheries management of public waters. On-site inspections of proposed changed affecting the aquatic environment will be made. Pre- and post- activity biological survey or field studies will be conducted as necessary.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.1924, A NEW LOOK AT THE OCEAN RECREATION MARKET
A.B. BIGLER, Compass Publications Inc., *Arlington, Virginia* 22209

The major problems in deficiency of shoreline recreation opportunities are discussed. These include (1) limited supply of prime beach and other shoreline recreation area, (2) discrepancy in available prime recreation shoreline with population location, (3) competition of other shoreline uses, and (4) effects of pollution and accelerated natural and man-made erosive forces. Various applications of marine science and technology are discussed for enhancing shoreline and near- shore recreation opportunities, including modification of shoreline configuration, development of offshore islands and platforms, preservation and enhancement of underwater areas, and artificial means of controlling waves and currents.

SUPPORTED BY No Formal Support Reported

2.1925, A STOCHASTIC MODEL FOR POLLUTION IN ESTUARIES
R.G. KRUTCHKOFF, Virginia Polytechnic Institute, Research Division, *Blacksburg, Virginia* 24061

The purpose of this investigation is to find a stochastic model for pollution and dissolved oxygen in estuaries. With this model it will be possible to predict the proportion of time that pollution will be above any given concentration or that dissolved oxygen will be below any given level. It is hoped that this information will result in better management of water resource systems and aid in forming more realistic restrictions on the use of estuaries for disposal pollutants.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1926, ANALYSIS OF WATER RESOURCES ADMINISTRATIVE AGENCIES
W.R. WALKER, Virginia Polytechnic Institute, Water Resources Research Ctr., *Blacksburg, Virginia* 24061

The aim of this research proposal is to analyze and evaluate the various administrative agencies in the State of Virginia which are concerned in some aspect with water resources management.

The intermediate goal will be to provide an objective assessment of administrative agencies currently operating in Virginia and then to suggest alternative arrangements that might better meet the objectives of the state. The ultimate goal is to formulate various administrative models best suited to accomplish a variety of objectives.

The problems associated with comprehensive planning, water quality, fisheries, recreation, etc., have become increasingly complex. It seems imperative that if policy decisions are to adequately reflect these varied interests that the governmental structure should be examined to determine and assess the various alternative forms.

An attempt will be made to compare the underlying laws creating each agency and to appraise the relative efficiency of the various programs in terms of such factors as economy, technical proficiency, political viability and social and land use effects.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1927, ANALYSIS OF ENGINEERING ALTERNATIVES FOR ENVIRONMENTAL PROTECTION FROM THERMAL DISCHARGES

A.F. AGNEW, Washington State University, State Water Research Center, *Pullman, Washington* 99163

This is phase I of a two-phase research project to analyze and evaluate current and proposed engineering practices used in the protection of the water environment from the impact of thermal power systems. The phase I project will last two years and will develop the analytical framework for evaluation. This research will investigate ecological and social accounting systems to supplement economic analysis of engineering impacts, and will formulate descriptions of alternative engineering solutions for protection of the water environment from the impact of thermal power systems. A methodology to assess the dynamic impact of a series of power plant developments in a region will be stressed.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.1928, A PROGRAM TO DETERMINE THE ECONOMIC LOSSES TO THE STATE OF WASHINGTON OF VARIOUS DIVERSION PATTERNS

C.B. MILLHAM, Washington State University, School of Science, *Pullman, Washington* 99163

The purpose of this research will be to improve in sophistication and capability a dynamic-programming model of a two-river, three-dam, six-time-period river system, coded for the IBM-360 computer. The improved model, designed to determine economic losses due to diversion, will be expected to handle return functions from power generation, irrigation, pollution abatement, and recreation, with constraints for flood control, navigation, and water quality. The program will be implemented with data for the Snake-Columbia river complex to obtain the economic impact of diversions from this system to the State of Washington.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1929, SOCIO-ECONOMIC AND LEGAL CONSIDERATIONS IN THE MANAGEMENT OF PUGET SOUND ESTUARINE RESOURCES

J.A. CRUTCHFIELD, Univ. of Washington, School of Arts, *Seattle, Washington* 98105

The long-range objectives of this project are (1) to identify, measure and evaluate the economic and social values of the marine resources of Puget Sound; (2) to provide analytical and empirical bases for efficient development and management of those resources; and (3) to develop alternative legal-political institutions for more effective implementation of these policies. Most important is the development of alternative legal-political arrangements for integrated planning and management of the Puget Sound estuarine system. There is an urgent need for further analysis of recreational usage of the system. Work will continue on the thermal effects of nuclear or fossil fuel power generating plants on various parts of the Sound. The socio-economic project should be linked to forthcoming programs designed to provide detailed small area information. Preliminary work on the impact of technological changes in ocean going vessels and in transfer of cargoes from vessels to land based transportation indicates a need for one or more cases studies of port relocation. A background task to be initiated this year involves the development (and some analysis) of various types of organizations of users of Puget Sound.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1930, LAW AFFECTING INSTITUTIONAL DESIGN FOR WATER QUALITY MANAGEMENT

P.N. DAVIS, Univ. of Wisconsin, Graduate School, *Madison, Wisconsin*

This is a tripartite legal study to investigate the legal and constitutional constraints on proposed broadening of powers of state agencies to regulate water quality and to operate pollution abatement works. The three areas of research are: (1) Common law of pollution in action - What influence if any does the common law riparian concept of 'reasonable use' have on the behavior of polluters? Field interviews will be conducted with riparian owners, and practicing attorneys. Local court records will be examined. Library research will determine the procedural and evidentiary problems in civil pollution actions. (2) Law affecting effluent charges -- library research will determine the legal and constitutional limitations on various effluent charge schemes proposed by economists. (3) Operation of pollution abatement works by the State of Wisconsin -- library research will determine the legal and constitutional constraints to broadening state agency powers to regulate water quality in a river as a single system and to operate pollution abatement works.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1931, LEGAL ASPECTS OF WATER RIGHTS AND WATER QUALITY IN EASTERN STATES

P.N. DAVIS, Univ. of Wisconsin, U.S.D.A. Nat. Resour. Ec. Div., *Madison, Wisconsin* 53706 (NRE3-2-52-01)

OBJECTIVE: Review, analyze, and compare the development and current status of laws applicable to water rights and regulation in the 31 Eastern States, with particular emphasis on ground water and water quality.

APPROACH: Analyses are made of state and federal statutes, constitutional provisions, court decisions and other factors applicable to water rights and regulation such as administrative regulations and contractual agreements, problems in acquiring or exercising private or public rights in surface and ground water for agricultural and other purposes, relationships to economic and physical factors including water quality considerations, and possible improvements in the applicable laws or their operation. Major emphasis in the analysis is on legal aspects of water quality in Wisconsin and other Eastern States.

PROGRESS: An article was published analyzing and comparing the suitability of Australian and American water allocation systems for use in the Eastern United States, examining the riparian and appropriation doctrines, temporal nonpriority permit systems and market place concepts. It concludes that a temporal nonpriority permit system may be the most suitable. A manuscript on water-use law and administration in Wisconsin is in the final publication stage and a preliminary manuscript on the origin and development of the riparian doctrine has been prepared. A manuscript reporting legal aspects of water quality management for the Wisconsin River area is in preparation. It includes a classification of water pollution cases according to riparian rights and nuisance doctrines, and tentatively concludes that: civil actions to abate pollution can be brought under rights or nuisance theories; the vast majority of cases recognize a common law right as against downstream riparians for a riparian to discharge wastes into a stream provided the discharge is reasonable, and no public or private nuisance is created; and the doctrine of comparative convenience has been applied in many pollution cases even though the courts frequently deny that the doctrine is applicable. A comparative analysis of the ground water laws of the 31 Eastern States was completed and will be reported in the next period.

SUPPORTED BY U.S. Dept. of Agriculture

2.1932, INSTITUTIONAL DESIGN FOR WATER QUALITY MANAGEMENT - A CASE STUDY OF THE WISCONSIN RIVER BASIN
I.K. FOX, Univ. of Wisconsin, Water Resources Center, *Madison, Wisconsin* (C-1228)

The Problem: Although a substantial amount of research is going forward on the technical and economic aspects of water quality management, relatively little attention is being devoted to the legal, policy, and administrative aspects. New policies and organizational arrangements are being tried but little scientific basis is being provided for institutional change that will assure proper implementation of the kinds of programs required for effective water quality management in the future.

The Objective: Using the Wisconsin River Basin as a region for study the specific objectives are: 1. To assess the advantages of a regional approach to water quality management 2. To evaluate the effectiveness of alternative institutional arrangements for conducting desirable programs of water quality management 3. To appraise the obstacles that are likely to be encountered in seeking desirable institutional changes.

Procedures: The research falls into two broad areas. One group of studies will seek to define the nature of effective programs for water quality management in the Wisconsin River Basin through application of recognized methods of water system design. The other group of studies will evaluate the effectiveness of alternative institutional arrangements for conducting water quality management programs through application of techniques of economic, political, legal, and administrative analysis.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1933, INSTITUTIONAL DESIGN FOR WATER QUALITY MANAGEMENT
I.K. FOX, Univ. of Wisconsin, Water Resources Center, *Madison, Wisconsin*

Specific objectives of this proposal are the following: 1. To integrate the set of studies undertaken in connection with the case study of water quality management in the Wisconsin River Basin into a final report which will indicate: a) The economies to be realized through a regional approach to water quality management, and b) the institutional patterns which offer most promise toward the realization of identified economies.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1934, ANALYSIS OF POLICY ISSUES POSED BY WATER AND RELATED LAND RESOURCES PROGRAMS IN THE METROPOLITAN REGION
I.K. FOX, Univ. of Wisconsin, Water Resources Center, *Madison, Wisconsin*

The excellent information and analysis developed by the Southwest Wisconsin Regional Planning Commission provides a solid basis for research into the effects of the policy-institutional framework upon water quality and riparian and flood plain land use in the major metropolitan area of Milwaukee. The proposed research will identify both the economic effect of the existing framework and the relationship between political participation and the incident of benefits and cost. An understanding of such relationships is of critical importance if policy advances are to be made and some of the urgent problems of metropolitan regions are to be solved.

Specific studies related to water quality management and riparian and flood plain land use will: a) estimate the economic efficiency of resource use relative to the program, b) estimate the incidence of benefits and costs to individuals and organizations according to useful categories, c) seek to establish the relative influence of the major features of the established policy-institutional framework, and individual and groups on the land use patterns and related public programs, and d) identify policy and institutional changes to improve economic efficiency and equitable distribution of benefits and cost, and expand the involvement of affected groups in the decision-making procedures to expand the relevancy of the program.

The first task to be taken in the summer of 1970 will be to review the water and land use patterns and programs and select specific program and land areas that merit intensive study. Government representatives and agency representatives will be consulted regarding study areas and topics.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1935, STUDY OF THE APPLICABILITY OF EFFLUENT CHARGES TO WATER QUALITY MANAGEMENT IN THE STATE OF WISCONSIN
I.K. FOX, Univ. of Wisconsin, Water Resources Center, *Madison, Wisconsin*

Many cities and communities in the United States have levied charges upon those who utilize the public sewage collection and treatment systems. However, to our knowledge there is no case where charges have been levied against those who discharge effluents directly into waterways. It is evident that the applicability and utility of effluent charges have not been thoroughly examined on the basis of carefully developed empirical information anywhere in the United States. This proposed study would seek to review the literature and experience on this subject and then test alternative concepts on the basis of empirical data developed for a specific river system.

The objectives of this study are as follows; (1) to arrive at alternative concepts of effluent charges, which may be applicable to the State of Wisconsin and to assess the potential advantages and limitations of each concept, (2) to examine the quality and economic consequences of applying alternative concepts of effluent charges in the Wisconsin River Basin by using empirical engineering and economic data presently being developed at the Water Resources Center.

It is to be emphasized that the report of this study will not recommend for or against the use of effluent charges in Wisconsin, nor will it offer other kinds of recommendations. The goal of the study will be to present completely objective, scientific analysis of all data and materials that can be marshalled so that state policy officials can make intelligent estimates of the physical and economical consequences of adopting one policy or another.

SUPPORTED BY Wisconsin State Government - Madison

2.1936, ECONOMIC AND LEGAL FACTORS IN PROVIDING, USING AND MANAGING WATER
W.B. LORD, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS01212)

OBJECTIVE: Determine the economic considerations that affect use and management of water, identify and describe rights in water and arrangements that regulate water use.

APPROACH: Multiple regression analysis of data collected from 60 artificial lakes in Wisconsin and an analysis of consumer behavior relating recreation to selected characteristics. Update an existing bibliography of publications concerning water rights and related topics. Provide a method to measure economic effects of state and federal water- based recreation projects on the economies of local political subdivisions; and illustrate the use of the model to analyze the adequacy of present and proposed public decision-making institutions relating to the development and expansion of water based recreation areas.

PROGRESS: Developed and administered a questionnaire to a statewide sample of families to test relative effect of perceived water pollution as a deterrent to water-based outdoor recreation. Collected and analyzed Wisconsin River Basin property values to estimate opportunity costs of reservoir drawdown. Reservoirs subject to pronounced summer drawdown and those with minimal fluctuation were included. Developed two computer simulation models which compute the location, amount and timing of hydroelectric power generation and value of power generated for any pattern of flows in Wisconsin River. The first model utilizes river flows and the operating characteristics of existing hydropower plants to determine power output. The second uses hydropower output together with power load analyses and operating and cost characteristics of thermal power generating facilities to estimate the alternative costs of meeting projected power de-

mands with any stipulated pattern of river flow. Together the simulation models provide a means of estimating the opportunity costs, in terms of changes in the overall costs of meeting anticipated power demands. Findings are that the existing system of fossil fuel and gas turbine plants is sufficiently flexible; and the old and relatively small-scale hydropower system is sufficiently inflexible; that changing the pattern of river flows within rather wide limits has little effect on the system operating costs and with current interest rates, technology and river flows, new thermal facilities can provide lower-cost power than new hydro facilities.

SUPPORTED BY U.S. Dept. of Agriculture

2.1937, SOCIAL AND ECONOMIC ASPECTS OF THE GREAT LAKES PROGRAM

R.A. RAGOTZKIE, Univ. of Wisconsin, School of Natural Sciences, *Madison, Wisconsin* 53706

The Socio-Economic portion of the Sea Grant activities continues many of the programs described in the annual progress report of July 1970.In particular, studies of Great Lakes shipping season and port development continue, as do the studies of recreational usage in the Green Bay area and elswhere, disposal of dredged spoil (2 projects) and Lake Superior fisheries.

New projects underway include a study of the legal jurisdictional aspects of use of the sea. Professor Richard Bilder has examined the new Canadian Arctic Waters Pollution Prevention Act as a possible pacesetter for expanding disagreements about national jurisdiction over coastal waters.

A new project to examine the assumptions and research needs for the overall plans for the Lake Superior basin has been begun. It is hoped that this project will result in a clear definition of new research needs to avoid degradation of this large pure body of fresh water.

SUPPORTLD BY U.S. Dept. of Commerce - N.O.A.A.

2.1938, GREEN BAY RESEARCH PROGRAM

R.A. RAGOTZKIE, Univ. of Wisconsin, School of Letters, *Madison, Wisconsin* 53706

The Program is being developed as a multidisciplinary effort to provide information on the total environment of Green Bay, which presently receives an exceptionally heavy load of industrial and domestic waste via the Fox River. Within a systems framework, the program has a goal objective evaluation of alternate solutions to the pollution problem. Inital efforts will assess the effects of man's socio-economic activities on the aquatic ecosystem as well as the reverse effect of current environmental conditions of the Bay on man's cultural activities. Included in the first phase of the program are studies dealing with : (1) the nutrient inputs from the Fox and Wolf River drainage basins (2) an acoustic profiling of the bottom and sub- bottom structure of lower Green Bay as related to sedimentation, (3) the primary productivity of algal and plant species, (4) the nitrogen fixation activity of the phytoplankton community in the lower Bay, (5) the role of the sediment environment in the degradation of organochlorine pesticides, (6) the effects of eutrophication on the benthos and plankton communities, (7) the flushing rate of the Bay in terms of the Fox River water, (8) the effects of perceived water quality on recreational pursuits, and (9) the economic impact of commercial shipping and the Seaway on the port of Green Bay.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.1939, INTERORGANIZATIONAL STRUCTURE RELATING TO WATER QUALITY ADMINISTRATION AND POLICY

W.K. WARNER, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

The general objective of the proposed research is to explore the interorganizational structure relating to water quality administration and policy in a selected geographic area. The specific objectives are to: (1) delineate the public and private organizations relating to water quality administration and policy, (2) determine the nature of their concern for, and/or impact on, such administration and policy, (3) explore the structure of relations among those organizations, and (4) explore the influence of the interorganizational structure on administration and policy.

The procedure for data collection will include compilation of existing information from publications, records, and other sources, but will rely mainly on interviews and/or questionnaires.

Results of this study should assist the understanding of problems in coordinating the diverse organizational programs concerned with water quality.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1940, VALUE OF THE GAME AND FISH RESOURCES IN RELATION TO THE FUTURE UTILIZATION OF THE WATER OF THE GREEN RIVER DRAINAGE IN WYOMING

G.T. BAXTER, Univ. of Wyoming, Water Resources Research Inst., *Laramie, Wyoming* 82070

The evaluation of the game and fish resources of the Green River, and their potential value under different types of future water utilization, particularly as anticipated under either the Wild Rivers Act or prospective state or federal developments including irrigation, industrial, trans-basin diversions, etc. This study will be essentially a refined inventory of the Green River, to include lengths of stream, water surface areas, stream classification, fish and game populations, general productivity, land ownership status, review of flow records as they pertain to fisheries, and present utilization of sportsmen. Various aspects of water quality - present and anticipated - will be analyzed. A prediction of the effects of various types of water utilization on the game and fish resources will be made on the basis of the data obtained during the course of the study.

Field work will be undertaken near Pinedale, Wyoming. All other portions of the study will be on the campus of the University of Wyoming.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.1941, WATER RESOURCE OPERATIONS STUDY

P.A. RECHARD, Univ. of Wyoming, Water Resources Research Inst., *Laramie, Wyoming* 82070

The basic purpose of the research is to learn more about the relationships among the many kinds and aspects of water resource operations, including how better to accomplish such multidisciplinary research.

As partial objectives, four study areas have been selected for investigation: (1) Criteria for Water Resource Planning, by studying the basic problems relating to Trans-basin Diversions in Wyoming; (2) Bio-Physical Relationships in the Hydrologic Cycle, by implementing the Multiple Use of the Water Resource Observatory; (3) The Interrelationships of Water Quality and Water Utilization; and (4) Principles of Analysis of Water Resource Operations.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

DESCRIPTION OF RESEARCH TASKS

3. SOLID WASTE MANAGEMENT

A. AGRICULTURAL SOURCES

Animal Feedlot Residues, Plant Waste, Farm Domestic Wastes, Manure Disposal.

3.0001, THE ROLE OF SOIL IN FARM WASTE MANAGEMENT
R.W. PEARSON, Auburn University, U.S.D.A. Soil & Wa. Cons. Div., *Auburn, Alabama* 36830 (SWC-026-BAU-3)

OBJECTIVE: Determine effects of organic farm wastes when applied to the soil at high rates, on soil properties, crop yield and quality, and runoff and percolating water quality.

APPROACH: Study will involve experiments in the Rhizotron for measurement of direct effects on plant roots, use of small plots for defining the effect of rate and method of application on crop yield, organic C accumulation and recycling of N, and P and K, and instrumented runoff plots for evaluating effect of wastes on runoff and percolating water. In addition, an evaluation of current lagoon design criteria will be made by periodic analysis of effluent and measurement of sediment in lagoons currently being planned by SCS for construction under A.C.P. cost sharing.

SUPPORTED BY U.S. Dept. of Agriculture

3.0002, EVALUATION OF THE NITROGEN, PHOSPHORUS AND POTASSIUM CONTENT OF POULTRY MANURE
L.H. HILEMAN, Univ. of Arkansas, Agricultural Experiment Sta., *Fayetteville, Arkansas* 72701 (ARK00546)

OBJECTIVE: Determine the nitrogen, phosphorus and potassium content of poultry manure under on-the-farm conditions and some of the factors affecting its composition. Determine crop response to applications of poultry manure of known nitrogen, phosphorus and potassium content, measure the effect of these applications upon soil chemical analysis.

APPROACH: Emphasis will be placed upon analysis of manure from commercial broiler houses. Statistical random sampling methods will be used in houses selected. Data collected will be subjected to statistical analysis for publication upon completion of chemical analysis. Field evaluation will be initiated after completion of the major part of the chemical analysis. The effect of rate and time of manure application on yield of pasture plants will be measured as well as any soil chemical changes.

PROGRESS: Field experiments were conducted to determine the effect of rate of broiler litter application on yield and plant nutrient uptake of grain sorghum, forage sorghum and soybeans. Yield and nutrient uptake of N,P,K was increased as rates of application were increased. A comprehensive greenhouse experiment was conducted using 5-10-15-20 tons litter per acre incorporated into the soil. Three soil types were used. Results show that the release of ammonia during decomposition drastically changes the soil nutrient balance and thus can be considered as a polluting agent. As soil clay content increased the soil chemical changes are decreased. Three months of daily leaching and mixing were required before adequate plant growth could be obtained. These soils similarly treated with broiler litter compost did not show these effects.

SUPPORTED BY Arkansas State Government

3.0003, EFFECTS OF GARBAGE COMPOST ON SOIL AND CROP PRODUCTION
C.C. HORTENSTINE, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-SI-01347)

OBJECTIVE: Evaluate the effects of garbage compost incorporation on the soil structure, fertility, and biological activity.

APPROACH: Laboratory greenhouse, and field studies will be conducted to determine the toxic or beneficial effects of garbage compost on plant life. Emphasis will be on the utilization of garbage compost as a plant nutrient source. The effects of this material on soil microbiological activity, organic matter, water holding capacity, cation exchange capacity, and pH will be determined.

PROGRESS: Effects of soil amended with municipal refuse (compost), cow manure, chicken manure, or sewage sludge on soil microbial activity were evaluated. The amounts of N which must be applied to obtain adequate nitrification in soil treated with compost were investigated. A minimum of 50 ppm of ammoniacal-N were needed to obtain nitrification within 6 to 8 weeks when 1g/100g soil (10T/A) were used. A general reduction in nitrification occurred when increased amounts of compost were added to soil treated with cow manure. African Giant earthworm survival was increased by as little as 2.5% compost added to Arredondo fine sand. Aspergillus niger growth in mycological broth was reduced by the addition of compost extract. In a field experiment, nematode populations (Helicotylenchus spp.) were reduced by additions of compost to Leon fine sand. After the second annual application of compost to phosphate mining tailings, sorghum seedhead weights were relatively greater than the preceding year. The overall average yield from all plots in 1968 was 272 g as compared to 669 g in 1969. The relative yields in 1969 were -- 100% (fertilizer only), 142% (fertilizer 35 tons/ha compost), 199% (fertilizer 70 tons/ha compost), 24% (35 tons/ha compost only), and 69% (70 tons/ha compost only). Where there was no growth of oat plants on the compost only plots in 1968, enough growth will be produced in 1969 for yield measurements. The increased sorghum and oat plant growth in 1969 indicates that there is a residual benefit from compost applications.

SUPPORTED BY Florida State Government - Tallahassee

3.0004, EVALUATION OF POULTRY MANURE AS A FERTILIZER
M.B. PARKER, Georgia Agric. Expt. Sta., *Griffin, Georgia* 30212 (GEO-01-0019)

OBJECTIVE: Evaluate Poultry manure as a fertilizer for corn, forage, and horticultural crops; determine the desirable or practical application rates for various crops; and determine the fertilizer nutrients needed to balance poultry manure as a fertilizer for various crops.

APPROACH: Manure rates will be combined with various fertilizer treatments. Residual effects of manure will be measured with corn and forage. Soil samples will be collected before initiation of each experiment and periodically thereafter to measure the effect of manure on soil pH and on the buildup of P and K in

the soil. Nitrogen content, yields, and clover percentage, when applicable, will be taken from the forage experiments. Yields and other pertinent data will be recorded from the row crop experiments.

PROGRESS: Four years results on the effects of chicken manure and commercial N on Midland bermudagrass forage have been obtained with the following measurements: Yield, ash, protein, fat, fiber, P, K, NFE, and D.M. disappearance (fistulated steer). These values by individual plots have been transferred to IBM cards and are ready for processing. Yield data indicate that manure N is about 60% as effective as commercial N. With N rates up to 400 lb/A., in increments of 100 lbs., forage N increased with N rates from 1.9 to 2.8%, P decreased with N rates from 0.33 to 0.30%, and K increased with N rates from 0.88 to 1.16%, N-P-K removal (forage yield X composition) indicates that the N- P-K ratio changes slightly with changes in N application. With 200 lbs. of N per acre the N-P-K ratio in the forage was 7.4 - 1.0 - 3.4 as compared with 9.3 - 1.0 - 3.8 ratio with 400 lbs. of N applied annually. These data also indicate that N rates annually should be above 200 lb./A. to promote yield, increase protein, and to insure that more N is being applied than removed by the crop. Forage removal of N with 100, 200, 300, and 400 lb/A. annually amounted to 143, 107, 90, and 80% respectively of that applied.

SUPPORTED BY Georgia State Government

3.0005, POULTRY MANURE MANAGEMENT ON FARMLANDS IN THE SOUTHEAST

S.R. WILKINSON, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Watkinsville, Georgia* 30677 (SWC-026-BAW-04)

OBJECTIVE: Determine pollution hazard to surface and ground water, soil, and crop plants of applying large rates of poultry manure to farmland. Determine changes in soil, plant composition associated with heavy applications, and the potential cause and effect of these changes on animal health disorders.

APPROACH: Apply poultry manure up to rates of 200 tons/year to small plots in Coastal bermudagrass, tall fescue, or fallow. Collect runoff from plots receiving either simulated rainfall or natural rainfall. Sample groundwater at several depths. Soil and forage samples from small plots receiving various treatment levels of poultry manure or of N, P, K, will be analyzed for inorganic and organic constituents important from nutrition or health viewpoint. Changes in soil and plant composition will be followed in a pasture ecosystem over a 4-year period with concurrent observations of animal disorders.

PROGRESS: Applications of 4, 8, and 16 tons of broiler house litter/ac/yr produced grass yields 50% of that achieved from 100, 200, and 400 lb/ac N from inorganic sources. High manure fertilization resulted in forage containing high levels of K, and K/CA Mg ratios well above the tetany-prone level of 2.2. Magnesium and calcium contents were safe from a tetany viewpoint because of previous liming with dolomitic limestone. Fescue fertilized heavily with broiler house litter accumulated NO3-N to 0.7%, with up to 35% of the total N in the non-protein fraction. Non-protein N increased with increasing levels of N-fertilization. Spring applications of more than 8 tons manure resulted in accumulation of non-protein N to potentially toxic levels. Two of 20 Angus cows developed fat necrosis after one year of grazing broiler litter fescue. None of the cows on the inorganic fertilized fescue (control) developed fat necrosis. Oral dosing with magnesium alloy bullets did not appear to be effective in preventing low blood serum Mg levels, and their short lifetime in the rumen of fistulated steers (about 3 weeks vs. 6 weeks expected) suggests ineffectiveness in preventing tetany. Coastal bermudagrass tolerated broiler house litter disposal at rates up to 20 tons per month during July, August, and September without loss of ground cover.

SUPPORTED BY U.S. Dept. of Agriculture

3.0006, AGRICULTURAL BENEFITS AND ENVIRONMENTAL CHANGES FROM USE OF ORGANIC WASTE ON FIELD CROPS

T.D. HINESLY, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-15-0362)

OBJECTIVE: Evaluate the use of digested sludge as a source of nutrients and water for growing field crops. Investigate factors relevant to water contamination and soil pollution when digested sludge is applied on crop land at various loading rates, frequencies, and time of year.

APPROACH: A set of 44 highly controlled small field plots or lysimeters will be constructed in such a way that all of the water that leaves each of them can be measured and samples collected for chemical and biological analysis. Laboratory and greenhouse studies will be designed to elucidate in greater detail the sequence of chemical and biological events that occur during the degradation of organic wastes under a wide range of treatments, soils, and environmental conditions.

PROGRESS: Phosphorus and nitrogen fertility for several crops can be supplied by digested sludge applications. Concentrations of Zn, Mn, and Fe in leaf tissue of corn, soybeans, and Reed canary grass were higher with than without sludge application while concentrations of Mg, Cu, and Ni were generally not affected by treatment. All of the metals accumulated in the soil but plant toxicities were not noted. Drain water samples collected from the South Farm lysimeters contained higher concentrations of nitrate-N, Zn, and Mn where sludge was applied. Runoff water from the N.E. Research Center plots contained only small amounts of ammonium-N and nitrate-N. The number of fecal coliforms in the sludge cake which has developed in the soil surface of the South Farm lysimeters decreased rapidly. No buildup of the fecal coliform population was observed within the sludge layer. Soil core samples were taken at the N.E. Agronomy research center where some plots have been amended with liquid digested sludge for two years. It was ascertained that, for these plots, the fecal coliforms did not develop within the plow layer. It was also found that the fecal coliform population rapidly decreased in samples of sludge and runoff water from sludge treated areas. Routine analyses for fecal coliform densities have been performed on the drain and runoff water samples originationg from the lysimeter facilities of the N.E. Agronomy Research Center. The data, so far accumulated, indicate that the sandy soil plots (Plainfield) are performing their filtering role satisfactorily.

3.0007, ABSTRACT SERVICE ON ANIMAL WASTE TECHNICAL LITERATURE

J.R. MINER, Iowa State University, School of Agriculture, *Ames, Iowa* 50010

The object of this work is to prepare abstracts of technical literature pertaining to the collection, transport, treatment and utilization of livestock wastes. Abstracts will be provided to WRSIC and to the FWPCA Laboratory in Ada, Oklahoma. The project will be initiated July 1, 1970 and is currently scheduled to terminate June 30, 1971.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0008, UTILIZATION OF LIVESTOCK WASTE TO ABATE POLLUTION

O.E. CROSS, Univ. of Nebraska, Agricultural Experiment Sta., *Lincoln, Nebraska* 68508 (NEB-11-031)

OBJECTIVE: Determine maximum allowable rate of loading livestock manure on cultivated soil without pollution of surface runoff or underground water, physical and chemical changes of soil resulting from manure loading rates, effects of manure loading rates on crop production, economic feasibility of manure applications on surface irrigated lands.

APPROACH: Test plots of irrigated sorghum followed by rye will be set-up. Variable will include: four rates of manure application, three depths of planting, three plant populations, and four replications. Quality and quantity of surface water runoff will be determined for natural rainfall and irrigation events. Deep probing soil samples will determine movement and accumulation of soluble contaminants in the soil profile and changes in soil physical and chemical properties.

PROGRESS: Because of variability of soil type, the field area initially selected for this project was abandoned. A replacement area was selected and preliminary soil borings were taken and the soil types classified. This second area was acceptable and negotia-

tions were finally completed allowing use of this area on this project. Soil borings have been completed and the soil types completed. The field area has been seeded to a winter cover. The late date of officially obtaining permit to use the area excluded the fall application of manure. A prototype instrument for sampling surface runoff has been developed and laboratory tested. The remaining 15 units of identical instruments are about 80% completed. Flumes have been made and are being calibrated to measure quantity of surface runoff. An accompanying depth of flow device is yet to be selected and procured.

SUPPORTED BY U.S. Dept. of Agriculture

3.0009, DECOMPOSITION AND DISPERSION OF EXCRETA FROM LAYING HENS AND TURKEYS

T.E. HARTUNG, Univ. of Nebraska, Agricultural Experiment Sta., *Lincoln, Nebraska* 68508 (NEB-22-015)

OBJECTIVE: Evaluate physical, chemical and biological decomposition parameters of excreta from laying hens using indoor collection pits. Investigate build-up and dispersion of wastes from high density turkey rearing systems.

APPROACH: Both macro and micro indoor tanks will be used evaluating the decomposition of laying hen excreta. Modification of the conditions (physical, chemical and microbiological) within these tanks will be studied. Aeration, its rate and agitation and its rate will be considered. Measurements will include pH, solids, temperature, odor, microbial types and numbers. Measurement of static and run-off wastes will be made on confined turkey production systems. Measurements will be made prior to populating the facilities with turkeys and subsequently after turkeys are placed in them. Measurements will include organic material, microbial types and numbers and chemical changes of soil.

PROGRESS: Intensive rearing of turkeys in semi-confinement were carried during this period. Two densities of pen space (18 sq.ft. and 13 sq.ft.) for toms and hens were compared to performance of range reared turkeys. No growth performance differences were noted between the densities with each sex. Growth was superior under semi-confinement than range conditions. Soil samples were taken prior to the growing season (8 wks. of age) and at the close of the test after 20 weeks for hens and 24 weeks on the toms. Measurement of the following factors are underway: General microbiol conditions, specific pathogens (Salmonella), parasite eggs, soil organic content, pH of soil, and soil mineral content. Original values have been measured for the first growing period during 1968. Comparisons will be made to determine trends in any build-up. Aeration system designs have been understudy for liquid indoor manure tanks. Excessive estimated cost prevented installation of early system. Presently new cost systems are being drafted.

SUPPORTED BY U.S. Dept. of Agriculture

3.0010, AGRICULTURAL WASTE INVESTIGATIONS

UNKNOWN, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00480)

Progress: Agricultural Waste investigations. Because of a lack of funds during the year little progress was made on the evaluation of the quantity of waste generated by agricultural pursuits. However, some parameters have been considered. It is felt that the initial studies should be limited primarily to the animal waste problem because of the nuisance factors and the potential health factors. Based upon the animal population of the state an estimate has been made that there is approximately 5000 tons of animal waste per day in the state. It is recognized that an estimate of the tonnage produced per day is of little significance unless one knows where these quantities are located, how it is disposed of and the method of disposal. Plans are being developed for a total inventory of the animal waste in the state. Sources of funds for conducting this survey are being sought. It is hoped that this survey can be started during 1969. Members of the staff were involved in the undergraduate and graduate teaching programs and High School Science Program, Science Fair. Parts or all of the following courses were taught: 370-403 (Chemistry of Pesticides), 375:407 (Environ. Toxicol. and Epidemiology); 015:497, 498 (George H. Cook Honors Program); 275:503 (Environmental Chemistry and Analysis). In addition a "Short Course in Pesticide Residues" was offered by the Department. Staff members served on several graduate student committees. Numerous inquiries from the staff and public on chemical problems were handled.

SUPPORTED BY New Jersey State Government - Trenton

3.0011, POLLUTION IMPLICATIONS OF ANIMAL WASTE

M.R. SCALF, U.S. Dept. of the Interior, Federal Water Quality Admin., *Ada, Oklahoma* 74820

The project is concerned with defining the chemical, physical, and biological properties of various animal wastes and describing the location and extent of the problem. In addition, present technology for collection, transportation, treatment, and utilization of animal wastes will be described along with past and current research. The final phase of the project is to indicate areas of future research.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0012, STABILIZATION OF ORGANIC WASTES FROM CATTLE FEEDLOTS IN SEMI-ARID CLIMATES BY COMPOSTING TECHNIQUES

W. ULICH, Texas Technological University, Agricultural Experiment Sta., *Lubbock, Texas* 79409 (901-031-B607)

OBJECTIVE: Determine the effects of various feedlot management systems on physical, chemical and biological properties of animal wastes, evaluate various procedures for aerobically and anaerobically composting these wastes, and develop systems for effectively composting these wastes thus reducing the potential for environmental pollution of soil, water, and air.

APPROACH: Beef cattle in feedlots will be fed three different rations and weekly samples of wastes will be collected over 120-day finishing periods. Treatments will be replicated with at least 12 animals per treatment. Rainfall simulation will be provided as needed to vary moisture conditions. Evaluations will be made of the influence of moisture vs. no moisture, roof vs. no roof, and solid floor vs. slotted floor. Samples of solid wastes will be analyzed for chemical and biochemical oxygen demand and small management systems for composting developed.

PROGRESS: Work was completed on facilities and equipment for collecting and stabilizing solid waste from cattle feedlots. Modifications on feedlots were made to enable the total collection of waste from cattle maintained under difficult management systems. Waste was also collected in environmentally controlled chambers to determine the effects of various climatic parameters on the characteristics of waste. Test equipment was purchased, computer programs set up, and laboratory and test equipment operators trained. A full analysis of accumulated waste and runoff was made. The waste was obtained from cattle fed various rations and held on lots with various surfaces, rainfall rates, and population densities. Aerobic and anaerobic solid waste stabilization studies were conducted under controlled conditions. A full chemical and biological analyses were made during the composting period. Three controlled dry type laboratory digesters have been constructed to determine techniques for speed-up of composting process and are now in operation.

3.0013, INVESTIGATION OF FISH DIVERSIFICATION AND DISTRIBUTION IN BIG CREEK AND ITS WATERSHED

G.L. HARP, Arkansas State University, Graduate School, *State University, Arkansas* 72467

Big Creek is a relatively small deltaic stream in Northeastern Arkansas. Of recent years it has been dredged in the interest of flood control for surrounding farm land. A dam near the headwaters also aids in this control. Lost Creek and Mud Creek are the major tributaries of Big Creek and collectively drain the Big Creek Watershed.

Only one prior investigation of fish population from Big Creek is known (Osoinach 1969). This survey was conducted two miles south c. Jonesboro, Arkansas, in a one-half mile stretch of water. Case (1970) provides physicochemical data from two locations on Big Creek. Jackson (1968) studied the physichochemical and ichthyofaunal characteristics of Lost Creek, but no survey has been conducted on Mud Creek.

It is the purpose of this study to determine qualitative variation of fish populations in Big Creek, Mud Creek, and Lost Creek and the co- existing physicochemical conditions. Further, the effect of pollution resulting fr om the Jonesboro sewage effluent and Broadway Meat Packing C ompany waste on the fish population will be determined.

SUPPORTED BY Arkansas State University

3.0014, REDUCING WASTES FROM COMMERCIAL FRUIT PEELING OPERATIONS
R.P. GRAHAM, U.S. Dept. of Agriculture, Western Utilization Res. Div., *Albany, California* 94710 (W3-1-165)

OBJECTIVE: Devise ways to peel fruit so that the peel will be free of added water and can be kept separate from the liquid effluent of the processing plant.

APPROACH: Investigate various procedures and equipment to eliminate the use of water in commercial fruit cannery peeling procedures. Design, test, and evaluate mechanical equipment for removal of peel after caustic soda treatment. Study other process modifications for fruits unsuited to dry caustic peeling.

PROGRESS:

SUPPORTED BY U.S. Dept. of Agriculture

3.0015, PROCESSING OF WINE FOR PRODUCT IMPROVEMENT AND POLLUTION REDUCTION
K. POPPER, U.S. Dept. of Agriculture, Western Utilization Res. Div., *Albany, California* 94710 (W3-1-162)

OBJECTIVE: Create markets for surplus grapes by developing methods for producing quality wines from non-wine varieties and decrease pollution attendant to wine making.

APPROACH: Investigate optimal wine flavor enhancement with Botrytis culture or extracts; vinification with Hansenula; chemical or biological substitutes for sulfur dioxide (or means of removal); improved fining with K-carboxymethylcellulose; ion exchange and dialysis processes for removal of tartrate. Test Uniflow filter and auxiliary processes for in-field separation of grape juice from pulp and debris; recovery of by-products from winery waste. Evaluate improved products chemically and organoleptically.

PROGRESS:

SUPPORTED BY U.S. Dept. of Agriculture

3.0016, NAVY ENVIRONMENT - FATE OF OIL AFTER A MAJOR OIL SPILL
N.A. VEDROS, Univ. of California, School of Public Health, *Berkeley, California* 94720 (N00014-69-A-0200-1001)

Technical Objective: With the exception of a few nuclear powered vessels, contemporary Naval fleets depend upon oil as their source of fuel. Occasionally carelessness, routine cleaning of fuel tanks, and accidents cause oil pollution of the marine environment. The objective of this effort is to determine the fate of oil in beach sand.

SUPPORTED BY U.S. Dept. of Defense - Navy

3.0017, ARCTIC ENGINEERING GEOLOGY (TAPS)
O.J. FERRIANS, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

State to which the project pertains: Alaska.

The principal activities and objectives of this project are: (1) for the Technical Advisory Board to the Department of Interior Task Force on Oil Development, review reports and proposals concerning the Trans Alaska Pipeline System (TAPS) in terms of their accuracy and merit, prepare (in collaboration with other government agencies) environmental and technical stipulations controlling the planning, construction, and operation of the proposed pipeline, and make recommendations in regard to possible alignment changes and special engineering-geologic problems, all of which are intended to help in minimizing any adverse effects the pipeline might have on the environment. (2) Collect, synthesize, and prepare for publication, engineering-geologic data that will aid in determining the proper route, design, construction, and maintenance of TAPS, and that will provide similar aid to other engineering activities generated by the petroleum- related development of northern Alaska. (3) Collect and synthesize basic geologic data concerning the character and distribution of permafrost and engineering soils along the pipeline route. (4) Evaluate new techniques such as remote sensing, that will aid in the rapid determination of th distribution and character of permafrost and other geologic- environmental features, and consequently, will facilitate solving engineering- geologic problems.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

3.0018, OIL POLLUTION OR STUDY--NSRDC
W.F. BURKART, U.S. Navy, Civil Engineering Lab., *Port Hueneme, California*

Technical Objective: Survey and collect data of oily-waste production and oily-waste processing elements/systems data from selected shore facilities.

SUPPORTED BY U.S. Dept. of Defense - Navy

3.0019, NAVY ENVIRONMENT - BIODEGRADATION OF OIL IN SEAWATER
W. HAYNES, U.S. Navy, Civil Engineering Lab., *Port Hueneme, California*

Technical Objective: The majority of the naval force afloat utilizes fuel oil as the predominant source of energy. Accidents, carelessness, and routine cleaning of fuel tanks often lead to oil pollution of the ocean. This research will provide a better understanding of how natural biological degradation takes place in the marine environment and will give an insight into methods for enhancing this natural process.

SUPPORTED BY U.S. Dept. of Defense - Navy

3.0020, BIODEGRADATION OF OIL IN SEAWATER FOR NAVAL POLLUTION CONTROL
N.S. STEHLE, U.S. Navy, Civil Engineering Lab., *Port Hueneme, California*

Technical Objective: To find microorganisms that are capable of quickly and efficiently degrading oil spills and thereby eliminate the hazards and nuisance of oil.

SUPPORTED BY U.S. Dept. of Defense - Navy

3.0021, THE ECOLOGY OF THE MICROBIAL POPULATION OF ACTIVATED SLUDGE
P.H. JONES, Univ. of Toronto, School of Public Hlth, *Toronto, Ontario, Canada*

(a) Proposed Research: A study of the population dynamics (b) Objective: To determine the dominant population under different conditions and thereby predict the optimum conditions for the degradation of specific high strength (or toxicity) industrial wastes. (c) Relation to the Health Field: To control waterborne transmission of toxic and pathogenic matter through better understanding of the mechanism of degradation or inactivation.

SUPPORTED BY Canadian Government - Ottawa

3.0022, POLYMER-IMPREGNATED CONCRETE PIPE RESEARCH PROGRAM
W.C. COWAN, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

The investigation and development of improved construction materials has become increasingly important as the economy and needs of this country continue to grow. Increasing construction labor costs necessitate the utilization of more economical materials. Polymer concrete conduits are proving resistant to aggressive

chemicals and will be useful in piping industrial wastes and other pollutants.

Before a system of polymer-impregnated concrete pipe can be specified for usage, a thorough design knowledge must be obtained and the service requirement standards must be investigated.

The program is designed to compare unreinforced precast polymer- impregnated pipe with reinforced precast concrete pipe. Goals of the program are to yield complete design information, service requirements, manufacturing techniques, and an evaluation of the economic benefits.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

3.0023, GEOCHEMISTRY OF MERCURY
A.P. PIERCE, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

State(s) to which the work listed herein pertains: Nevada, Idaho.

The objectives of the project are to make environmental studies of mercury distribution in and around selected mineral deposits, to determine physical and chemical causes controlling the distribution of mercury and to develop methods of interpreting mercury anomalies. Studies to date have involved geochemical reconnaissance of mercury in soils, rocks, ore and gangue minerals.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

3.0024, NORTHERN ANTHRACITE FIELD
M.J. BERGIN, U.S. Dept. of the Interior, Geological Survey, *Washington, District of Columbia* 20242

State(s) to which the work listed herein pertains: Pennsylvania. Long-range objective is to geologically map and study the Northern Anthracite field. Emphasis is on the coal bed in rocks of Pennsylvanian age: (1) Their correlation, distribution, stratigraphy, and structure, (2) their status as energy resources, (3) their depletion by mining and accessibility for additional development, (4) the environmental problems caused by their mining. Distribution, stratigraphy, and structure of the older rocks surrounding the Northern Anthracite field are being studied to determine regional correlations and relationships to the Southern, Western-Middle, Eastern-Middle, Anthracite fields. The currently authorized project entails geologic studies of the southwestern part of the field, namely in the Kingston, Pittston, Wilkes-Barre East, Wilkes-Barre West, Nanticoke, and Shickshinny quadrangles. Upon completion of mapping here, probably in less than 5 years, studies will be undertaken in the northeastern part of the field, namely in the Avoca, Scranton, Carbondale, Waymart, and Forest City quadrangles.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

3.0025, NAVY ENVIRONMENT - BIODEGRADATION OF OIL POLLUTANTS BY YEAST AND YEAST LIKE FUNGI
D.G. AHEARN, Georgia Inst. of Technology, Graduate School, *Atlanta, Georgia* 30332 (N00014-71-C-0145)

Technical Objective: The majority of the Naval force afloat utilizes oil as the source of energy. Accidents, carelessness, and routine cleaning of fuel bunkers often lead to oil pollution of the marine environment. This research will provide a better understanding of how biologic degradation takes place in the marine environment and will give an insight into methods for enhancing this natural process.

SUPPORTED BY U.S. Dept. of Defense - Navy

3.0026, SURVEY OF REFUSE ORIGINATING ABOARD NAVAL VESSELS AT SEA
G.C. NICKOL, U.S. Navy, Ship Research & Dev. Lab., *Annapolis, Maryland* 21402

Technical Objective: To determine the approximate quantities and characteristics of solid wastes discharged from the various classes of naval ships while at sea and when berthed. To put emphasis on rubbish characteristics such as plastics, non combustibles, etc. that would affect incineration, compaction or grinding. This is part of a CNO- sponsored plan toward alternative methods for disposal of shipboard rubbish.

SUPPORTED BY U.S. Dept. of Defense - Navy

3.0027, UNIT OPERATIONS STUDIES - WHITE PHOSPHORUS AND WASTE CONTROL
W.P. JUNKIN, U.S. Army, *Edgewood Arsenal, Maryland*

Technical Objective: Study means for controlling wastes and effluents from plants which load white phosphorus (WP) into munitions systems. Develop leak detection devices.

SUPPORTED BY U.S. Dept. of Defense - Army

3.0028, BIODEGRADABILITY OF ORGANIC COMPOUNDS INCLUDING DETERGENTS, METAL WORKING FLUIDS, ETC. THAT MAY CONTAMINATE WATER
M.R. ROGERS, U.S. Army, Natick Laboratories, *Natick, Massachusetts*

Conduct studies of the biodegradability of organic compounds to develop standards and test procedures for their use in Army materials including detergents, metal working fluids, gelled fuels, and liquid hydrocarbon fuels.

SUPPORTED BY U.S. Dept. of Defense - Army

3.0029, VEGETATIVE RECLAMATION OF IRON MINE WASTES
S.G. SHETRON, Michigan Technological Univ., Ford Forestry Center, *L'Anse, Michigan* 49946

Research will be conducted on the establishment of vegetation on nonfertile waste rock dumps, retaining tailings dams and tailing deposits at iron and copper mines in Michigan's Upper Peninsula. Results to date show that adequate growth of grass and legumes can be obtained with proper fertilization. Treatments varied from no fertilizer, sawdust, sawdust-fertilizer, and fertilized three times. Growth and survival of tree species was poor. Establishment costs varied from $20 to $1,200 per acre, depending on the type of treatment used.

New studies have been initiated concerning the following: (1) application of vinyl polmers for preimmergent wind and water erosion control, (2) soil micro-biological regimes before and after vegetative establishment, (3) development of wind breaks, (4) planting of tree and grass species that are not native to Michigan s Upper Peninsula.

SUPPORTED BY Cleveland Cliffs Iron Company - Michigan

3.0030, SINKING METHODS FOR REMOVAL OF OIL POLLUTION FROM WATER SURFACES
E.C. ROSHORE, U.S. Army, Waterways Experiment Station, *Vicksburg, Mississippi* 39180

Technical Objective: To identify all existing oil sinking materials that could be used in cleanup operations associated with massive oil spills and leaks from tankers and drilling plantforms. To develop standard procedures for testing each material. To qualitatively and quantitatively evaluate the effectiveness and partial utility of each material.

SUPPORTED BY U.S. Dept. of Defense - Army

3.0031, NAVY ENVIRONMENT - BIODEGRADATION OF OIL SLICKS IN MARINE ENVIRONMENT
R. BARTHA, Rutgers the State University, School of Arts, *New Brunswick, New Jersey* 08903 (N00014-67-A-0115-0005)

Technical Objective: With the exception of a few nuclear powered vessels, contemporary Naval fleets depend upon oil as their fuel, occasional carelessness and routine cleaning of fuel tanks, among other things, cause oil pollution of the marine environment. This effort will be devoted to obtaining a better understanding of how biological degradation of oil takes place and may give an insight into means of artificially increasing this process.

3. SOLID WASTE MANAGEMENT

SUPPORTED BY U.S. Dept. of Defense - Navy

3.0032, STUDIES ON MODIFICATIONS OF SOLID INDUSTRIAL WASTES
C.S. GROVE, Syracuse University, Research Institute, *Syracuse, New York* 13210

Collection of data and information on the 'Survey Review - Solid Wastes: Scope, Quality and Quantity' will be continued, through literature coverage but emphasizing personal solicitation and confirming data through direct correspondence and interviews. It is planned to prepare semi-annual reports for distribution. The experimental studies on modifications of solid industrial waste beds will be continued to investigate the effects of porosity, particle size, and leaching rates on rapidity of possible rehabilitation and potential load-bearing capacity and growth of desirable vegetation. Two types of solid wastes will be studied further: (1) Solvay process wastes; and, (2) Ground overburden and washings from anthracite coal mines. The rates of removal of soluble salts from soils and insoluble particulates has been shown to be some function of the organic humus content. This parameter will be investigated in more detail.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0033, ORGANIC MATTER RELATIONSHIPS OF SPOIL BANKS
J.P. VIMMERSTEDT, Ohio Agric. Res. & Dev. Center, *Wooster, Ohio* 44691 (OHO00383-S)

OBJECTIVE: Study tree litter and root conversion to organic matter in spoil banks.

APPROACH: Determine abundance and biomass of macroscopic soil animals on spoil banks. Energy available in litter and dead roots for animals and rates of consumption by soil aniamls. In 1967 plan to establish colonies of earthworms.

PROGRESS: Earthworms (Lumbricus terrestris L.), placed on an acid (pH 3.5-4.0) shale spoil bank revegetated with black locust (Robinia pseudoacacia L.) or in undisturbed cores from the spoil bank surface, actively buried litter and ectorganic humus, depositing castings on the surface. In undisturbed cores in a greenhouse, burial of a 60 mm thickness of litter and ectorganic humus was quite complete after 180 days. Exchangeable K, Ca, and Mg and available P contents of the mineral spoil increased as follows: K from 0.16 to 0.19, Ca from 1.7 to 2.7, and Mg from 1.8 to 2.5 meq per 100 grams of spoil; available P increased from 1.7 to 4.2 ppm. Earthworm activity did not influence growth of red oak (Quercus rubra L.) seedlings. Earthworms, caged on the spoil bank, survived for at least 2 years, and reproduced. They buried or consumed about 5 metric tons/ha of litter and 23 metric tons/ha of ectorganic humus. In the greenhouse, during 175 days, 14 metric tons/ha of litter and 68 metric tons/ha of humus were consumed or buried. The weight of earthworm casts deposited on the surface of the cores was equivalent to 16.8 metric tons/ha. Earthworms can promote the incorporation of organic matter into mineral spoil.

SUPPORTED BY Ohio State Government

3.0034, NAVY ENVIRONMENT ENZYMATIC REMOVAL OF OIL IN THE MARINE ENVIRONMENT
R.K. GHOLSON, Okla. St. Univ., School of Arts, *Stillwater, Oklahoma* 74075 (N00014-71-A-0004-0001)

Technical Objective: With the exception of a few nuclear powered vessels, contemporary Naval fleets depend upon oil as their fuel. Occasionally carelessness and routine cleaning of fuel tanks, among other things, cause oil pollution of the marine environment. This study is devoted to the isolation of microbial enzymes systems which will degrade hydrocarbons.

SUPPORTED BY U.S. Dept. of Defense - Navy

3.0035, FOOD PROCESSING WASTES
M.R. SODERQUIST, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00899)

OBJECTIVE: Initiate a research program dealing with the wastes generated by Oregon's primary food processing industry, involving: evaluation of waste occurrence and waste disposal systems currently being used; estimation of the extent and seriousness of present and future problems; establishment of guidelines for the selection of research which could most reasonably help alleviate the critical problems; and implementation of individual research projects involving waste reduction, waste treatment and by-product development.

APPROACH: The industry will first be surveyed by a questionnaire designed to reveal the origin, quantity, nature, composition, importance & cost & method of disposal or utilization of solid, aqueous & gaseous wastes. This will be followed by one-site analyses, using a portable laboratory built for this purpose, of specific waste streams to gather more detailed data on each segment of the industry. From these data, problems will be categorized by common methods of approach & research will be undertaken to alleviate these problems.

PROGRESS: The first phase of the project has been completed. The questionnaire results have been tallied, analyzed and interpreted. A report on the findings will soon be published. To implement the second phase of the project, outlined under 'Approach' on Form AD 416, a portable laboratory has been designed and is now being constructed. This will be used in an on-site sampling and analysis program beginning this summer.

SUPPORTED BY U.S. Dept. of Agriculture

3.0036, FERMENTED FOOD PRODUCTS
H.Y. YANG, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00677)

OBJECTIVE: Improve the quality and processing methods of fermented food products. Describe the nature of defective fermentation of food products and provide means of control. Develop new food products through the fermentation process. Define the fermentation processes in terms of specific reactions which change the flavor, textural and other sensory attributes of the products.

APPROACH: Work on the pear wine formulation and pickle coloring and flavoring will continue through the next year. Pear concentrates from the Hood River area will be tested as well as the Medford concentrates. Pear wastes retained by the pulper and finisher will likewise be tested for their suitability in the production of formula wines. These wastes, though not fit for making pear concentrates, retain about 13 per cent of sugar and most of the other pear constituents. They are not utilized now and they cost money to be hauled away, in addition to the pollution and contamination problems.

PROGRESS: During the year, efforts were concentrated on the fermentation of vinifera grapes as there was much interest on this subject generated throughout the state. A total of 733 pounds of grapes were crushed and fermented into wine, for experimental purposes. The varieties of vinifera grapes tested were Pinot Noir, Gewurztraminer, Sylvaner, Pinot Chardonnay, White Riesling, Zinfandel, Semillon, Sauvignon Blanc, Cabernet Sauvignon, and Pinot Blanc. Some of the varieties were picked three or four times during the season. The unusually cold and rainy season hurt the grapes, as it did other crops. The vinifera grapes were high in acidity and low in sugar content. Tight clusters were moldy, although in some cases the mold was Botrytis cinerea (noble mold), which is considered desirable for the development of sugar and flavor in some grapes. Two small rooms were converted to fermenting rooms with the installation of refrigeration units. The rooms are being used for fermenting, stabilizing, and aging of wines.

SUPPORTED BY Oregon State Government

3.0037, PHYSIOLOGICAL EVALUATION OF TREATED TOXIC WASTES
G.R. BOUCK, U.S. Dept. of the Interior, Federal Water Quality Admin., *Corvallis, Oregon* 97330

The project seeks to evaluate the needed degree of waste treatment for Paper Trade Wastes. Various life stages of Pacific Salmon and steelhead trout are the test organisms and these are exposed to the above wastes for thirty days or more using continu-

ous renewal of toxicant. Physiological tests include histopathology, autofluorescence of tissues, protein composition of plasma and tissues, enzymes in plasma and routine hematology.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0038, SLIME CONTROL ASSOCIATED WITH PULP MILL EFFLUENTS
M.D. KNITTEL, U.S. Dept. of the Interior, Federal Water Quality Admin., *Corvallis, Oregon* 97330

The purpose of this investigation is to learn the minimum requirements of nutrients that support the growth of Sphaerotilus natans. Further, the project plans to define the carbon and nitrogen source that supports growth of this bacterium. This information will be helpful to those who must design effective waste treatment methods for industrial wastes.

A second major area of this project is to find, test and develop effective biological control methods for S. natans.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0039, CARBONIZATION OF MUNCIPAL AND INDUSTRIAL WASTE
D.E. WOLFSON, U.S. Dept. of the Interior, Bureau of Mines, *Pittsburgh, Pennsylvania* 15213

The Bureau of Mines-American Gas Association (BM-AGA) pilot plant is available and is capable of processing thermally degradable feed stocks and recovering the solid, liquid, and gaseous products in sufficient quantity for analysis and processing.

Samples will be obtained from refuse collection depots and sources of industrial waste. Pyrolysis experiments will be made at temperatures up to 900 degrees C to determine the yield and quality of the products. Other variables to be studied include bulk density, moisture content, and the separation or inclusion of noncombustible constituents.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0040, REVEGETATION OF HIGHLY ADVERSE SITES CREATED BY COAL MINING
R.J. HUTNIK, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01745)

OBJECTIVE: Determine levels of physical and chemical factors restricting revegetation. Identify and develop resistant species and varieties. Test soil amendments to ameliorate limiting factors. Determine effects of sewage and industrial wastes on spoil materials.

APPROACH: Both laboratory and field measurements will be made to determine properties of sites for comparison with known tolerance levels of plants. Selected species and varieties will be screened in greenhouse tests using spoil substrates. Mulches and chemicals will be laboratory and field tested as ameliorating agents. Sewage sludge, effluent, and fly ash will be used in laboratory lysimeter tests.

PROGRESS: The environment of a deep-mine refuse bank was studied. Soil moisture and temperature were measured. Although the refuse dried out rapidly near the surface, it remained moist throughout the summer at a depth of nine inches; the surface reached a maximum of 160 F, and on several occasions, it remained above 140 F for more than four hours on all aspects except the northwest; the temperature 1/3 inch below the surface reached a maximum of 131 F, and stayed above 122 F for 4-1/2 hours; temperature gradients as steep as 40 F between the surface and 1/3 inch below, and 48 F between the surface and 1/3 inch above were measured. A study was made of the chemical quality of percolate through mine spoil after applications of sewage sludge and weekly application of sewage effluent. Pyrite-bearing spoil was used with a 4.1 pH. Renovation of the solution was satisfactory for Ca, P and LAS. S concentrations decreased to 50 ppm S in the 38th week. Concentrations of Fe were low except for sludge treatments where they had decreased to 30 ppm after thirty weeks. K concentrations remained above effluent concentrations for sludge treatments throughout the study. The pH of the percolates remained about 4 for all treatments except for some sludge treatments where it increased in thirty weeks to about 6.5. Ammonia was generated in some sludge treatments. Percolate from some sludge treatments was discolored and had an offensive odor.

SUPPORTED BY U.S. Dept. of Agriculture

3.0041, RECOVERY OF AMINO ACIDS FROM POTATO STARCH FACTORY SECONDARY WASTES
W.L. PORTER, U.S. Dept. of Agriculture, Eastern Utilization Res. Div., *Wyndmoor, Pennsylvania* 19118 (E3-6-54)

OBJECTIVE: To reduce pollution by potato starch factory effluents by laboratory evaluation of new ion-exchange methods of recovery of amino acids from such wastes; construct a portable demonstration plant, recover crude amino acid mixtures and protein for use in utilization studies and market development, and to obtain cost estimate and design for full scale operation.

APPROACH: Apply newer ion-exchange techniques to EU process for recovery of amino acids from potato processing waste. Obtain information to expand to plant scale, including charge and elution behavior, resin life. Characterize amino acid product, composition, BOD and COD of process influent and effluent. Apply Dutch steam-injection process for protein recovery to clarify input. Determine if reverse osmosis is practical or potential way to increase concentration of values in protein water. Construct portable demonstration protein and amino acid recovery plant for use at starch factories to show application of process to pollution abatement, produce 500 pounds of each product. Determine product value in feed, food, drug or other field. Estimate costs for process as applied to effluent from 10, 30 ton potato starch plants as means of pollution abatement.

PROGRESS: Coarse membrane reverse osmosis modules have been tested for protein removal from waste stream. Flow rates were considerably lower and small molecule retention higher than hoped. Causes are being sought. Batchwise rather than continuous mode is more efficient for reverse osmosis preconcentration for subsequent processing. Ion exchange removal of cations before recovery of amino acids improves recovery of both materials. Process variables (temperature, flow rates, volumes, concentrations) being optimized and control instruments developed. Conductivity monitoring for both cation and amino acid columns is satisfactory. A run of 3 complete cycles was successful, with solids reductions nearly theoretical. Operating procedures for organic acid recovery are being reduced to minimal; eluate solids concentration of nearly 7% has been attained. First uses of this fraction as detergent builder replacing phosphates were promising. Material balances have been calculated prior to process cost estimates.

SUPPORTED BY U.S. Dept. of Agriculture

3.0042, NAVY ENVIRONMENT - BIOLOGICAL OXIDATION OF PETROLEUM POLLUTANTS
J.F. FAIR, Houston Research Incorporated, *Houston, Texas* 77023 (N00014-71-C-0307)

Technical Objective: The majority of the Naval force afloat utilizes oil as the primary source of energy, accidents, carelessness, and routine cleaning of fuel bunkers often lead to oil pollution of the marine environment. This research will provide a better understanding of biological degradation of hydrocarbons and will give an insight into methods for enhancing this natural process.

SUPPORTED BY U.S. Dept. of Defense - Navy

3.0043, TREATMENT OF TAILINGS TO ENHANCE PLANT GROWTH AND PROMOTE STABILIZATION OF TAILINGS
H.B. PETERSON, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00726)

OBJECTIVE: Compile a bibliography of biological stabilization or utilization of mine tailings. Survey and screen plant species for use in stabilizing mine tailings. Determine growth deterrents and nutrient deficiencies and evaluate various treatments on mine tailings to promote plant growth. Study effects of tailings-grown plant material on animal life.

3. SOLID WASTE MANAGEMENT

APPROACH: Wastes from copper, lead, zinc, uranium and gold milling operations will be studied. Laboratory and greenhouse tests will be made to determine phytotoxic agents in tailings and levels of these agents required to produce toxicity in plants. Deficiencies of nutrients required to support plant life will be determined in the tailings, and studies will be made to alleviate these deficiencies through soil additions or ammendments. When accepted vegetative growths are attained the plants will be fed to animals to determine if materials extracted from tailings create adverse health effects.

PROGRESS: Field trials were initiated on tailings ponds. Results to be presented in annual report to FWPCA. Major activity on progress preparation of manuscripts. A bulletin is in preparation.

SUPPORTED BY: Utah State Government

3.0044, TECHNOLOGICAL CHANGE IN FOREST INDUSTRIES

W.R. BENTLEY, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS01364)

OBJECTIVE: Develop and test hypotheses concerning relationships between causal factors and effects of technological change in the forest industries; identify and model effects of present and possible future levels of technology in the forest economy.

APPROACH: Develop hypotheses and measures relating technological changes to causal factors using tool of historical analysis, statistical analysis, and industrial interviews; investigate the secondary effects of technological change using an input-output analysis.

PROGRESS: First, investigations regarding the nature of technological change have identified three sources of increased value productivity in the forest industries: 1. Response to changes in the relative prices of inputs (esp. labor, equipment, timber, and energy) and product outputs. 2. Shifts in present input combinations to attain greater technical efficiency. 3. Initiation of essentially new technology in processing and/or products. Second, the primary causal factor is hypothesized to be managerial quality. Efforts are now being made to design methods for testing this hypothesis and providing measures of technological change (productivity increase) associated with each of the sources listed above. Third, specific empirical research is focusing on pollution abatement by the pulp and paper industry. It is hypothesized that technological change alone has been the major course of reduced pollution loadings by pulp and paper mills. This problem has been formulated in terms of positive and negative increments to present net worth associated with reductions in 5-day BOD and suspended solids. A technological matrix has been formulated for each major pulping and paper-making process (Fig. 1). Technical stages in each subprocess reflect sequentially lower loadings. A cost matrix by plant size is now being constructed to predict loadings associated with economically optimal plants and the cost of decreasing loadings still further. Older plants with mixed levels of technology also can be simulated.

SUPPORTED BY: U.S. Dept. of Agriculture

3.0045, PACKAGING

R.S. KURTENACKER, Univ. of Wisconsin, U.S.D.A. Forest Products Lab., *Madison, Wisconsin* 53706 (FPL3507)

OBJECTIVE: Develop procedures for efficient utilization of wood, wood-base materials and composites in pallets and containers, emphasizing lower grades and lesser used species; integrate transportation environment and engineering analysis into containers to improve protection and reduce damage.

APPROACH: Improve necessary properties and characteristics of paperboard components to impart optimum performance to container; increase the use of wasters, residues, and bark through engineering design of paper sheets to develop necessary properties; improve production efficiency by analyzing component and equipment characteristics; improve fastener systems, utilize tree residues and foreign woods to augment timber supply; establish transportation environment conditions, especially those involving shock and vibration; and utilize this information to develop efficient container designs, establish blocking and bracing requirements, and provide desired degree of product protection; consider impact on waste and pollution.

PROGRESS: Review of related literature involving development of package design criteria and work on water-resistant corrugating adhesive continued. In order to improve corrugated fiberboard compressive strength, the effect of glue skips and means of eliminating them were studied. Theoretical and actual bending stiffness of corrugated fiberboard were compared to provide a basis for computing the anticipated bending stiffness of a combined board from preselected components. Improvements were made on the method for measuring flute height. Additional performance data was obtained on behavior of pallet fastening systems involving resilient adhesives. Studies proved serviceable bin pallets can be made from Applachian hardwoods, also pallet stringers with built-up cutouts utilizing low-grade hardwood could provide better wood utilization than conventional stringers with sawn cutouts and perform equally as well. Knowledge developed on severity of shock experienced by container contents should result in more efficient utilization of wood-base cushioning material. A method of studying puncture and tear resistance of paper bags and an equation for determining the performance index of sacks were developed.

SUPPORTED BY: U.S. Dept. of Agriculture

C. MUNICIPAL SOURCES

3.0046, CONSERVATION OF RESOURCES IN MUNICIPAL WASTES

C.E. SCARSBROOK, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA-03-0017)

OBJECTIVE: Determine the effect of municipal garbage compost on the growth of plants and on soil properties.

APPROACH: Compost will be soil incorporated and used as a mulch to determine its effect on the establishment and growth of roadside cover. The nutrients required for growth of various plants in garbage compost will be determined. The rate of decay and duration of effects of compost on soil will be measured in the field and in the laboratory. The effect of compost on the activity of herbicides in the soil will be determined.

PROGRESS: Garbage composts produced at the municipal plant, Mobil, Alabama, were used in all experiments. To obtain normal growth of Gahi- 1 millet, it was necessary to add extremely large amounts of N and P to composts. Where the composts were kept moist in the greenhouse for one year the compost released sufficient nutrients for fair plant growth whereas initially the composts would not support plant growth. There were no toxic effects of composts on germination of millet. Compost reduced the toxicity of excessive rates of trifluralin and fluometuron added to soil but had little effect on bromacil, nicloram, and simazine. Laboratory incubations experiments show that N added with the composts is first immobilized and then gradually released over an 18-week period. Nitrogen contained in the compost is not appreciably mineralized after 18-weeks incubation. Compost used as a mulch for chrysanthemums and petunias was as satisfactory as sawdust and fine straw. Where compost was added to a potting mixture there was a reduction in height and weight of chrysanthemums, a reduction in weight of geraniums, a reduction in leaf size and weight of gloxina, an increase in flowerhead length in snapdragons, and an increase in plant height and flower number in easter lily. Chrysanthemums grown in soil containing compost contained 3-4 times more B than plants grown in peat amended soil.

3.0047, IMPROVEMENT OF CEREAL GRAINS UNDER IRRIGATION

A.D. DAY, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-2014-4156-003)

OBJECTIVE: Develop new cultivars of barley and oats for hot-steppe regions with higher yields, higher quality, more resistance to lodging, and more resistance to the Barley Yellow Dwarf Virus (BYDV). Breed new salt-tolerant cultivars of barley, wheat, and corn. Conduct in-depth studies to determine the ef-

fects of municipal sewage effluent on the quality of protein in small grains.

APPROACH: New cultivars of barley and oats will be developed for the southwestern U. S. using the Pedigree and Recurrent Selection methods of breeding. New salt-tolerant barleys and wheats will be selected from Composite Crosses of spring barleys and wheats from the World Barley and Wheat Collections. A new salt-tolerant corn will be selected from an Arizona Corn Composite Cross. Grain from cereal grains grown with sewage effluent will be analyzed to determine the effects of sewage effluent on protein quality (amino acids).

PROGRESS: Results from experiments in which 39 barleys, with geographical origins similar to 'California Mariout', were germinated in salinized water and soil cultures were reported in the Agronomy Journal. One-third of the barleys studied equalled or exceeded California Mariout in germination in highly saline cultures. Their emergence in salinized soil followed the same trends as their germination in petri dishes. Most commercial varieties had lower germination salt-tolerance than California Mariout and the more tolerant USDA introductions. At moderate salinity levels, most barleys had uniform emergence in soil cultures while at higher levels of salinity only the salt-tolerant barleys produced satisfactory seedling growth. The two-year experiment conducted at Tucson, Arizona to study some of the effects of withholding water from wheat at different stages of growth was published in Progressive Agriculture. The most critical period for water in the growth of spring wheat planted in December was the jointing stage of growth.

3.0048, COMPILATION OF READINGS AND CASE MATERIALS ON TECHNOLOGY ASSESSMENT
C.H. DANHOF, George Washington University, Prog. of Pol. Stud. Sci. Tech., *Washington, District of Columbia* 20037

The assessment of technology is a special characteristic of government regulatory activities having to do with the consideration of the need for constraints on the use of new technology or on well established technology which can be subjected to new analysis using detection equipment.

This project involves the selection of case studies in government action resting upon a technology assessment and involving the application of values established by statute or administrative action. Cases are classified as relating to human health and safety, the environment (including air, water, noise), solid wastes, and with a small section devoted to population questions. The compilation concludes with a selection of proposals relating to the improvement of the regulatory process, principally through improvements in the assessment procedures. Each case is provided with a brief foreword placing its subject-matter in perspective.

3.0049, CHEMICAL INDICATORS OF FECAL POLLUTION
J.E. SINGLEY, Univ. of Florida, School of Engineering, *Gainesville, Florida* 32601

The proposed research project will focus attention upon the development of a qualitative and quantitative analytical procedure for the determination of a product of higher animal metabolism that occurs in the feces in high enough concentration to be detected.

The initial phases of the study will concentrate upon the optimization of a gas chromatographic analysis for coprostanol (5 B-cholestan-3 B-ol). Preliminary studies have shown good sensitivity and accuracy. The major improvements that need to be made are in the preliminary extraction and cleanup steps and in column characteristics. Other analytical techniques will be evaluated in an attempt to develop a rapid, simple and accurate method of analysis.

The ultimate objective of the study is the replacement of the standard bacteriological methods of analysis of fecal pollution.

3.0050, CLAY-WATER SYSTEMS IN RELATION TO ENGINEERING PROPERTIES OF CLAY MATERIALS
W.A. WHITE, State Geol. Survey, *Urbana, Illinois* 61801

The study concerns the effects of rocks, detergents, water softeners, fabric softeners, and starch on the plastic properties of earth materials.

There have been land creeps and landslides in residential developments in Illinois and other states where there are discharge fields from septic tanks. It is possible in some of these instances that the compounds in the effluents from the septic tanks have contributed to the instability of the land. The effects of these compounds have been studied, and they seem to affect the plastic properties of clay materials to some extent--some more than others. The project is being continued, using two or more products that occur in household wastes.

3.0051, THE EVALUATION OF ACROLEIN AND ANALOGS TO DEODORIZE SEPTIC WATERS
W. GARNER, Midwest Research Institute, *Kansas City, Missouri* 64110

Acrolein and other alpha, beta unsaturated aldehydes react instantaneously and completely with H2S in septic aqueous systems. Additionally, they react with -SH bearing enzymes in bacteria and inhibit growth. The titled project is investigating the chemistry, microbiology, engineering, and economics of this patented process with the view to developing it for field use in wastewater systems and agricultural waste management.

SUPPORTED BY: No Formal Support Reported

3.0052, APPLICABILITY OF ARDOX CATALYSTS TO THE OXIDATION OF MUNICIPAL SEWAGE EFFLUENTS AND OF WASTES PRODUCED DURING MANNED SPACE FLIGHT
B. INTORRE, Arde Incorporated, *Paramus, New Jersey* 07652

To perform a study to determine the applicability of ARDOX Catalysts to the oxidation of municipal sewage effluents and of wastes produced during manned space flights.

Using the appropriate Ardox catalyst and continuous operation of the reactor system, experimental runs shall be carried out to determine the effect of operating variables upon the extent of oxidation and to select optimum values of the variables for carrying out further work with municipal secondary effluent.

SUPPORTED BY: U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0053, EFFECT OF MUNICIPAL SEWAGE PLANT EFFLUENT UPON AQUATIC SNAIL POPULATIONS
R.C. CRAIG, State University of New York, School of Arts, *Plattsburgh, New York* 12901

A study is in progress to determine the effect of sewage plant effluent on the numbers, types, and distribution of snails in the Saranac River, Plattsburgh, New York. This study was suggested when a search for snails along the north and south banks of the river revealed that no snails were located on the south bank below the City of Plattsburgh sewage plant discharge pipe while 50 yards away on the north bank numerous snails (4 different genera) were located. The same general type of vegetation exists on both sides of the river.

In addition to the snail population study, water samples from the river will be analyzed for nitrates, phosphates, copper, mercury, and chlorine content. Water temperature, pH, dissolved oxygen, and turbidity determinations will be recorded.

A control area further south on the shore of Lake Champlain has been selected which approximates the Saranac River area in vegetation, water movement, and bottom type but lacking the gross pollution of the river.

3.0056, SOLID WASTE CELLULOSE DEGRADATION BY THERMOACTINOMYCES
F.J. STUTZENBERGER, Weber State College, School of Arts, *Ogden, Utah* 84403

The role which actinomycetes play in the degradation of cellulose in solid waste materials has been relatively neglected. A cellulolytic actinomycete of the genus 'Thermoactinomyces' was found to be prevalent in the open windrow composting process at the Joint PHS-TVA Composting Project at Johnson City, Tenn. the cellulase which it produced in pure culture exhibited pH and temperature optima (pH 6.0 and 65 C) identical to those of the crude cellulase extracted from compost samples of windrows undergoing degradation. These findings indicate that this actinomycete is of prime importance in cellulose degradation during the composting of municipal solid wastes.

In efforts to increase the rapidity and completeness of the solid waste composting process, knowledge of the requirements and capabilities of active flora and their extracellular enzyme systems is essential. Such knowledge will provide a basis for meaningful manipulation of physical and chemical conditions to improve the degradation of important solid waste materials such as cellulose. The present proposal includes research to: 1) determine the minimal nutritional requirements for rapid growth and cellulase production by this 'Thermoactinomyces' species, 2) study the effects which metals common in high concentrations in municipal solid waste have upon growth and cellulase production, 3) ascertain the stability of the cellulase under varied conditions of pH, temperature, and ionic strength, 4) measure the efficiency with which the actinomycete degrades cellulosic materials covering a wide range of enzymatic susceptibility, 5) characterize the sugars which the actinomycete cellulase system liberates during cellulose hydrolysis.

D. COLLECTION, TRANSPORTATION, PROCESSING AND DISPOSAL METHODS

Includes Incineration, Ocean Dumping, Sewage Treatment and Processing, Sanitary Landfill Management, Sludge Application to Cropl;ands

3.0057, ECONOMICS OF GRADE A DAIRYING
J.H. BLACKSTONE, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA00221)

OBJECTIVE. Obtain physical input-output physical input-output data and study costs, returns, and efficiency of different systems of milk production, evaluate problems in herd management and milk production and use controlled experiments to solve these problems, and determine alternative systems of milk production that result in increased stability and higher incomes.

APPROACH. Dairy herds owned by Alabama Experiment Station System that are in a unique position will be used in various types of controlled experiments--conventional pasture, drylot, combinations of two, different levels of grain feeding, various kinds of stored roughages, etc. Physical and economic data from these experimental units will be used to compare returns and efficiencies of different systems and provide information for budgeting alternative systems.

PROGRESS. Number of Alabama Grade A dairy herds has been decreasing while remaining ones have been getting larger in capital investment, number of cows milked, and in total pounds of milk produced. Dairy herds owned by Auburn University were decreased by 2 during the year. Remaining herds have increased capital investment, number of cows milked, and milk production. Changes have been made to conduct controlled research on herds with concentrates mixed with silage and fed outside the milking barn versus concentrates fed in barn and silage outside; all drylot feeding versus daytime drylot and nighttime grazing; use of individual stall housing versus open lot pens; use of different barn cleaning methods; and with 3 different methods of solid waste disposal. New capital investments have been made in automated feed equipment, new feed storage tanks, flush water holding vats, stall housing and new holding lots. Several short-term tests were run in order to check equipment and to acquaint cows with new arrangements. All inventory data, capital cost data, and related economic data have been collected. Forms have been developed for keeping day-to-day records.

SUPPORTED BY U.S. Dept. of Agriculture

3.0058, SWINE WASTE TREATMENT AND DISPOSAL
R.E. HERMANSON, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA00276)

OBJECTIVE. Determine design criteria for swine waste treatment system consisting of multiple treatment units with various methods of final disposal. Final system effluent shall not contribute to stream pollution.

APPROACH. Treatment system consisting of series connected anaerobil lagoon, aerated lagoon or oxidation ditch and final aerobic lagoon. BOD loading rate will be varied to afford determination of system design parameters. Influent and effluent characteristics will be determined for each stage of treatment. Final disposal of system effluent will be by discharge to a stream. Irrigation, field spreading, and high intensity soil incorporation will be investigated for disposal of effluent from each stage of treatment.

PROGRESS. Research performed. A survey of existing lagoons on several of the outlying substations, an evaluation of the effect of floor types and methods of waste disposal on the performance of nursery pigs was initiated at the Sand Mountain Substation, and a waste treatment and disposal system was constructed at the main station swine farm. Observations of BOD, COD, pH, temperature, percent solids, sludge accumulation and general performance of lagoons were made. Results of these observations will be used for evaluation of loading parameters in this research and for updating of recommendations. Facilities at the Sand Mountain Substation will include 2 slatted-floor houses. One house will use a liquid pit beneath the floor for manure collection with disposal. An experimental treatment and disposal system has been developed and constructed at the main station swine farm. The system consists of an anaerobic lagoon followed by an aerobic lagoon that is aerated mechanically. The system was designed to economically provide flexibility in loading rates and detention times. Treatment and disposal of the waste can be by stream dilution, irrigation, field spreading and high intensity soil incorporation.

SUPPORTED BY U.S. Dept. of Agriculture

3.0059, WATER POLLUTION BY DAIRY FARM WASTES AS RELATED TO METHOD OF WASTE DISPOSAL
T.A. MCCASKEY, Auburn University, School of Agriculture, *Auburn, Alabama* 36830

Initial work of this project will include an examination of existing waste disposal systems on Alabama dairy farms and the apparent correlation of the waste with water contamination. Immediately available for this phase of the study are four dairy farms of the Alabama Agricultural Experiment Station System

representing several soil and water conditions of the southeast. A number of large commercial dairies in the vicinity of Alabama cities will contribute to the study.

Field research will include studies of four systems of dairy farm waste disposal: 'dry' manure accumulation and periodic spreading with conventional equipment; semi-liquid manure collection in underground tanks and spreading on fields in liquid form using tractor-drawn equipment; liquid manure spreading via irrigation systems at frequent intervals; aerobic lagoons. Sampling sites will include: feedlots, croplands, pasture lands, streams or waterways, farm ponds, groundwater.

Laboratory studies will include the enumeration of the following groups of bacteria: fecal coliform and streptococci, salomonellae, shigellae, Clostridium perfringens. Chemical tests such as COD, pH, alkalinity, water hardness, nitrate and nitrite content, tannin and lignin, etc. will be made.

Field and laboratory data will be correlated with the view of developing guidelines on acceptable waste disposal systems for commercial dairy farms.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

3.0060, WATER POLLUTION BY DAIRY FARM WASTES AS RELATED TO METHOD OF WASTE DISPOSAL
T.A. MCCASKEY, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA-06-0110)

OBJECTIVE: Relate criteria of water runoff from dairy farms employing various methods of waste disposal. Study significance of health-related microbes in dairy farm-fed streams in relation to method of waste disposal. Develop guidelines for controlling water pollution and undesirable odors caused by dairy farm waste. Determine economics of dairy waste disposal systems.

APPROACH: Examine existing waste disposal systems on selected Alabama dairy farms and study four methods of waste disposal at Alabama Agricultural Experiment Substations. Disposal of waste by the conventional, tank wagon, irrigation, and by the lagoon methods will be evaluated by water and soil tests in view of developing guide lines on acceptable waste disposal systems for dairy farms.

PROGRESS: Dairy waste was applied at an equivalent rate of 20 tons 'dry' waste per acre to runoff plots to simulate conventional, irrigation, and slurry methods of waste disposal. Runoff from each of the disposal plots and a control plot were analyzed for manure pollutants. Runoff from liquid disposal plot contained more fecal organisms, nitrogen, ammonia, solids, and had higher BOD and COD values than runoff from the other plots. Pollutants decreased more rapidly in the runoff from liquid disposal plot than from the semi-liquid or 'dry' waste disposal plots. Number of fecal bacteria increased 87% in soil of the 'dry' waste plot, and 324 and 397%, in liquid and semi-liquid disposal plots. Nitrate-nitrite level in the soil of all waste disposal plots increased from 0.02 to about 0.35 mg per 10g soil 60 days after waste application. Application of waste to field plots by a semi-liquid system at 0.6 tons dry weight equivalent per application did not cause a substantial increase in manure pollutants in the soil. A slight increase occurred in number of fecal bacteria in the soil from the plot receiving weekly applications. Land disposal of waste at the present rate and frequency will not cause a significant increase in manure pollutants in soil.

SUPPORTED BY Alabama State Government

3.0061, DEVELOPMENT OF WASTE STABILIZATION LAGOONS FOR APPLICATION IN ALASKA
S.E. CLARK, U.S. Dept. of the Interior, Federal Water Quality Admin., *College, Alaska* 99701

The project objectives are to evaluate waste stabilization lagoon efficiencies while operating under Alaska's severe climatic conditions and to develop operation techniques which will assure adequate waste treatment throughout the year. A pilot plant located at Eielson Air Force Base is being placed in operation this winter utilizing the theory of storage of the winter's wastes with spring, summer and fall discharge. A polishing lagoon will be placed in operation during the warmer months of the year.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0062, SUBARCTIC AERATION LAGOON INVESTIGATIONS, BIOKINETIC REQUIREMENTS AND SEASONAL AND DURNAL EFFECTS ON NUTRIENT BALANCE
S.E. CLARK, U.S. Dept. of the Interior, Federal Water Quality Admin., *College, Alaska* 99701

The project objectives are to evaluate: a. To develop design and operational standards for artificially aerated waste stabilization lagoons under Alaskan conditions. b. To evaluate parameters contributing to effluent quality, power and maintenance costs, reliability under rapidly varying ambient conditions, and the effects on the receiving waters.

A pilot plant has been constructed and will be placed in operation at Eielson Air Force Base.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0063, COMPLETE MIX ACTIVATED SLUDGE UNIT PROCESS ADAPTION TO LOW TEMPERATURE
S.E. CLARK, U.S. Dept. of the Interior, Federal Water Quality Admin., *College, Alaska* 99701

The project objectives are to evaluate the influences of Alaska's severe climatic conditions upon the activated sludge process in the loading range between 0.02 and 0.40 no. 5-Day BOD per no. of MLVSS, and to develop techniques for minimizing the detrimental climatic influences. Laboratory scale pilot studies utilizing settled sewage are in progress to determine low temperature biokinetics including a major emphasis devoted to developing techniques of effective solids separation that will be feasible in the Alaska environment and under the Alaskan inflated economy. Large scale outdoor pilot facilities are planned.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0064, WATER AND WASTE MANAGEMENT (MUST)
H. PARTO, Garrett Corporation, *Phoenix, Arizona* 85034 (DADA17)

Technical Objective: This work is designed to reduce water resupply and waste disposal problems encountered in field operations of MUST hospitals. Haulage of fresh water over long distances is a continuing problem. The disposal of hospital wastes, which are often contaminated, is complicated by operations in extremely cold temperatures, when wastes cannot be buried, or in high water table areas where burial is likewise impractical.

SUPPORTED BY U.S. Dept. of Defense - Army

3.0065, CHEMICAL REACTIONS OF WOODS AND BARKS
C.L. BRINK, Univ. of California, Agricultural Experiment Sta., *Berkeley, California* 94720 (CA-FO-FPL-1834)

OBJECTIVE: Investigate known processes of wood pulping to determine their suitability for California wood species. Study the products of pulping reactions including liquor, solids, and gases and their potential for commercial utilization as fertilizers, papermaking fibers, hardboard, and industrial chemicals. Study the effect of chemicals on the constituents of wood and bark, namely, cellulose, lignin, and hemocellulose.

APPROACH: Recognizing that pulping offers an excellent means of utilizing residuals developed at California sawmills and other wood working plants as well as in the forests, pulping reactions will be studied to the end of producing high quality pulps, and minimizing to the greatest extent possible polution of water and air. The pulping liquor from the several processes studied will be investigated to determine the nature of the lignin and other constituents and their potential use. The problem of gas recovery in pulping operations will be investigated. Novel approaches to the problem of developing a pulping process suitable for the California scene will be tried.

PROGRESS: Organic Wastes Processing. Pyrolysis-Combustion. The two-stage, continuous (50-150 lb/hr dry solids, experimental unit designed for complete conversion of dissolved,

suspended or solid organic wastes to fuel gas by pyrolysis has been constructed and equipment shake-down is in progress. Provision has been made for combustion of the gas which in practice would be burned to produce energy. Inorganic and/or organic chemical recovery are optional. Analytical techniques were perfected for separating sulfur-containing from other organics, isolation of each compound, and determination of its structure. Wet Combustion study of organic wastes disposal by air oxidation of dissolved or suspended solids in an aqueous system using communited wood as a standard material was completed. Data reduction using computer programs was developed to provide energy and material balances for each reaction. Optimum conditions were indicated for organic chemical and/or energy recovery. Bleaching pulp using oxides of nitrogen appears technically feasible; economic study in progress. Water pollution reduced by burning organics solubilized. Alkaline nitrobenzene oxidation of wood study continued.

3.0066, COMPREHENSIVE STUDIES OF SOLID WASTES MANAGEMENT
C.G. GOLUEKE, Univ. of California, School of Engineering, *Berkeley, California* 94720

The objective of the project is to develop solutions to regional problems of solid waste management through a program of research which brings together the competence of specialists from such fields as planning, economics, administration, operations research, engineering, public health, and sociology or political science. Through participation of graduate students in such disciplines, it is also intended to orient personnel in a wide variety of fields to the problem of solid wastes which will confront them in professional practice. The research itself is concerned with developing an overall wastes generation and management model, establishing methodology for evaluating the waste generating potential of land dedicated to any plan of use; developing models and subsystems by which feasible alternative decisions can be evaluated from an economic and engineering viewpoint and fitted in with sociological and political realities, and developing new technologies. Finally, the objective is to relate research and real problems through a close association between researchers and practitioners in public works management.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0067, TRANSIENT LOADING EFFECTS IN THE ACTIVATED SLUDGE PROCESS
D.F. JENKINS, Univ. of California, School of Engineering, *Berkeley, California* 94720

The current and proposed research is investigating (a) the short- term transient behavior of activated sludge systems in the most significant practical situation in which they occur, i.e., in reactors such as contact stabilization units where deviation from completely mixed conditions exist, (b) the physical properties of activated sludge that influence its removal by sedimentation/clarification and the variation of these properties with organic loading and sludge growth rate, and (c) the chemical, biochemical, and microbiological properties of activated sludge in an attempt to provide a better representation of active solids than the measurement of VSS and to determine the reason for the deviations of activated sludge systems from a theoretical growth model.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0068, OCEANOGRAPHIC FACTORS IN THE FUNCTIONAL DESIGN OF WASTE DISPOSAL SYSTEMS
J.W. JOHNSON, Univ. of California, School of Engineering, *Berkeley, California* 94720

In the design of waste disposal systems, such as ocean sewer outfalls, cooling water waste lines from nuclear power plants, etc., a large variety of technical problems remain to be solved to place such sound design on a sound scientific basis. The three major areas of studies have been: 1. The mixing of a buoyant jet being discharged horizontally at the water surface. 2. The mixing of a series of buoyant jets being discharged horizontally from both sides of a manifold placed at the bottom of a tank. 3. The mixing caused by the mass transport associated with surface waves having a circular normal directional spectra.

The laboratory work done previously at UCB in regard to Item 1 was re-examined, and compared with the results of work done subsequently by other institutions. These results were then compared with the two sets of prototype data with which the investigators were aware: The Pacific Gas & Electric Plant at Morro Bay, California, and the discharge of the Columbia River into the North Pacific Ocean. The data compared favorably, on a gross basis. It became evident that the laboratory work should be extended to much smaller values of Froude number and that the statistical fluctuations of temperature and salinity in the mixing jet should be studied in detail.

In regard to Item 2, the results of the studies of single jets by a number of investigators were compared, and a preliminary report written on the findings. It was evident that no additional work need be done on the portion of a single jet between the bottom and surface, but that there is essentially no information on the interaction of multiple jets from a manifold. The laboratory equipment has been designed, constructed and tested, with preliminary tests made.

The results of a theoretical study of Item 3 have been negative, in the sense that there appears to be no mixing caused by the mass transport of waves with a circular normal distribution. However, the theoretical study was linear, and there may be some non linear mechanism that exists.

A 3-year study terminating 30 June 1970.

SUPPORTED BY University of California - Berkeley, Cal.

3.0069, LIVESTOCK ENVIRONMENTAL FACILITIES
T.E. BOND, U.S. Dept. of Agriculture, Agricultural Engineering Div., *Davis, California* 95616 (312-021-B216)

OBJECTIVE: Develop design criteria for structures and related equipment for providing optimum environments for livestock (principally beef cattle and swine) production.

APPROACH: In the laboratory, obtain basic bio-engineering data on relationships between environment and physiological responses--with principal emphasis on Southwest climatic conditions and heat and moisture transfer mechanisms. In the field, measure and map radiant fluxes from sky, ground, and surroundings. From the bio-engineering and radiant flux data develop and evaluate shelters, shades and related equipment for economically providing optimum production environments.

PROGRESS: The weight gains of pigs at 20 F above their maximum- growth air temperatures (89-92 F) were 0.76, 0.70 and 0.54 lb/day, respectively, with low, medium and high relative humidities; efficiency of feed use was 3.87, 4.06 and 4.72 lb feed/lb gain. Insulated trailer vans were modified for controlled-temperature animal studies. The first test with 8 individually-fed pigs per trailer at either 55 or 85 F was completed and there were no differences in production due to thiamin levels of 0.6, 0.85, 1.1 and 1.35 Mg/Kg. Animal waste disposal in desert climates was investigated using manure pits (anerobic) under slatted-floor pens for beef cattle, connected to adjacent lagoons (aerobic). Total solids, volatile solids, nitrogen and BOD are being measured; this study is still in progress. Solar reflectance values were determined for several colors of poultry, swine, sheep and cattle surfaces. In a study of the effect of wind, mud and rain on winter beef cattle production, cattle in concrete pens gained 25% less (7.04 lb feed/lb gain) when exposed to forced wind and 50% less (11.6 lb feed/lb gain) when artificial rain was added to wind; cattle in mud pens gained 10% less with wind; cattle in mud pens with shelter gained 30% less than on concrete but 40% less when forced wind was used. Tests of cooled drinking water for beef cattle and degree-hours tests with beef cattle at El Centro are still in progress.

SUPPORTED BY U.S. Dept. of Agriculture

3.0070, SOLID WASTE DISPOSAL AND BIRD HAZARD TO AIRCRAFT
H.L. COGSWELL, Calif. State College, School of Natural Sciences, *Hayward, California* 94542

Emphasis of this three year study is in the San Francisco Bay Region, California, where seven major and 13 smaller airports as well as 37 solid waste disposal sites are located on lowlands near bay shores. At 31 of the disposal sites many gulls (Larinae) of three to five species gather daily to feed. Many flight routes they follow to nighttime roosts and distant lakes transect the approach/takeoff zones of several airports where more than 1000 gulls often pass over 1000 feet in ten minutes. Baywide populations vary seasonally from 130,000 in October-December, to 5200 in June, 70 to 95 per cent being associated with disposal sites most of the day. Fifty seven of 236 gulls tagged have been subsequently identified individually. These and records here of more than 70 California Gulls marked in Wyoming, indicate considerable shifting of many gulls among disposal sites although population levels are rather consistent at each. Detailed analyses of populations and recurring movements are in progress.

Data are also being gathered on starlings and blackbirds, and applicability of Bay region findings elsewhere in the U.S.A. is being evaluated by visits to various airport-water disposal site combinations..

3.0071, CHARACTERIZATION OF THE ACTIVATED SLUDGE PROCESS AT THE HYPERION TREATMENT PLANT

A.D. LEIPZIG, Los Angeles Bd. of Pub. Works, *Los Angeles, California* 90012

The objectives of the testing program to be carried out at the Hyperion Treatment Plant in Los Angeles can be divided conveniently into two parts. The first objective will be to develop a set of plant characteristics which will represent the average (24 hr. composite) performance of the plant.

The second objective (corresponding to Phase II) will be to study the time dependent or transient behavior of the plant by varying the influent stream in some predetermined way as a function of time and then making measurements of flow and concentration at various stations as a function of time (at one hour intervals). The purpose of Phase II will be to generate the necessary data to develop a dynamic or time dependent mathematical model for the activated sludge process.

The model will then be used to select the most practical method for controlling the plant to achieve improved plant performance and a more uniform water quality at the effluent weirs of the final settler.

3.0072, STUDY OF WET GRINDING UNITS FOR HOSPITAL SOLID WASTE

B.S. WEINTRAUB, Los Angeles Co. Health Dept., *Los Angeles, California* (PH110-224-67)

The purpose of this contract is to determine if wet grinding units which discharge to a sewerage system are suitable and practical as a method of hospital solid wastes disposal.

In performance of this contract, the Contractor shall: Install wet grinding units in two hospitals served by a municipal sewerage system. One hospital must be over 200 beds in size and be located on a trunk sewer. The second hospital must be between 50 and 100 beds in size, and located in a suburban area and served by a secondary sewer. In one hospital, two units are to be installed; one at a central collection point, and one in a soiled work room. In the second hospital, the unit will be placed only at the central collection point. The contractor shall purchase the wet grinding units with the advice and consent of the local plumbing authority to assure compliance with applicable codes.

Summary of Final Report: The tremendous upsurge in the use of disposable materials, especially in modern health care facilities, particularly hospitals, has brough about a need for new methods of disposal. In an effort to discover methods for disposal of single use syringes, needles, paper and plastic products, Los Angeles County Health Department studied the use of wet grinding units to dispose of hospital solid wastes trhough the sanitary sewer. Results show that any such installation must be tailored to the individual hospital, and the staff must be instructed in the use of the system, but that grinding poses no insurmountable problems relating to sewer, or the water treatment facility.

3.0074, RECOVERY OF CHEMICALS AS A MEANS OF BRINE DISPOSAL

R.L. CLARK, Environmental Qual. Eng. Inc., *Oakland, California* 94610

Candidate products, processes, and sites will be identified for the recovery of chemicals from desalting plant effluents. Associated economic and process design data will be assembled, and environmental problems will be examined. Feasibility criteria for the potential of the process will be established. Based on this information and criteria, block flow diagrams will be developed for approximately eight products and sixteen processes. A preliminary market analysis will be performed on each product under consideration. The interrelation between chemical and desalting plants will be evaluated to include such factors as descaling, effluent brine concentration and composition, and changes in residual waste disposal resulting from chemical recovery.

Based on these exploratory studies, the most promising products, processes and sites will be selected for a preliminary engineering and economic analysis. This will include determination of the smallest plant size that will support chemical recovery. The results of this analysis will be used to (1) identify the most promising integrated facility for desalting-chemical recovery, and (2) determine research efforts necessary for advancement of chemical recovery methods for brine disposal.

3.0075, TREATMENT OF MUNICIPAL SECONDARY EFFLUENT BY GRANULAR ACTIVATED CARBON

J.D. PARKHURST, Los Angeles Co. San. Dist. 21, *Pomona, California*

The objective of the project is to develop economic and design information on the application of granular activated carbon to removing the refractory organic materials from a municipal secondary effluent. The equipment consists of four 6-foot diameter, 10-ft. deep beds of 16 X 40 mesh carbon over which the secondary effluent is passed downflow at a Rate of 7 gpm/ft.2. The total flow is 200 gpm. The product COD is maintained between 3 and 12 ppm by thermal regeneration of the exhausted carbon in a 6-hearth Herreschoff furnace. The carbon exhaustion rate has been about 3500/mg. Carbon losses per cycle have been between 7-1/2 and 10% but it is believed that this would be reduced to 5% in a larger- scale operation. A cost estimate for a 10 mgd plant indicated that total costs would be about 8 cents/1,000 gal. Studies have shown that, between 4 and 10 gpm/ft2, contact time alone is controlling. Studies are underway to determine the effect of application rates below 4 gpm/ft.2 and to evaluate the effect of particle size and source of carbon.

3.0076, SOIL AND WATER MANAGEMENT SYSTEMS FOR DISPOSAL OF DAIRY AND POULTRY WASTES

S.A. DAVIS, Univ. of California, U.S.D.A. Soil & Wa. Cons. Div., *Riverside, California* 92507 (SWC-026-GRI-5)

OBJECTIVE: Develop adequate soil and water management practices to allow the disposal of dairy and poultry wastes on land while preventing pollution of soil and water and maintaining the yield and quality of crops.

3. SOLID WASTE MANAGEMENT

APPROACH: Laboratory, greenhouse, lysimeter, and field experiments will be conducted for maximizing disposal rates of dairy and poultry wastes while avoiding surface water and ground water pollution with excess nutrients or organic materials. Lysimeters will be used to study rates of nutrient and organic compound movement in soils of various textures and to determine optimum water table levels for a nitrification-denitrification sequence to dissipate nitrates. Soil and water management practices, such as methods of incorporating manure into the soil, frequency of irrigation and amounts of water applied, in combination with various rates and frequencies of manure application to soils, will be studied in the fields. Effects on quality and yield of crops and movement of nutrients and organic compounds into ground water will be evaluated. Greenhouse experiments will be used to study the potential for reducing yield and quality of crops with very high rates of manure and to identify the mode of action if detrimental effects are observed.

PROGRESS:

3.0077, NITRATE POLLUTION FROM DISPOSAL OF DAIRY WASTE

P.F. PRATT, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (SWC-026-GRI-5X)

OBJECTIVE: Determine the capacity of various soils to oxidize dairy waste under various soil management practices while maintaining the yield and quality of crops and preventing contamination of drainage and ground waters with nitrates.

APPROACH: Laboratory, greenhouse, lysimeter and field experiments will be conducted with emphasis on application of existing knowledge of the N cycle to the development of management practices that will reduce pollution of water with nitrates. Lysimeters will be used to determine the optimum water table level for a nitrification-denitrification sequence in soils of various textures. Various rates and frequencies of manure will be applied to soils in the field to evaluate effects on crops and nitrates in ground water in relation to profile modification and irrigation management. Manure at rates up to 400 tons per acre will be applied in greenhouse experiments to determine effects on yields and quality of crops, and the leaching necessary to remove soluble salts.

3.0079, A SOLID WASTES MANAGEMENT SYSTEM FOR THE BAY REGION

J.H. JACOBS, San Fran. Planning Association, *San Francisco, California*

Like most other American cities, San Francisco is running out of dumping sites for solid wastes. Experts estimate that the region will run out of disposal capacity by 1977. The problem is compounded by the obsolete technology of incineration and the multiplicity of refuse collections agencies-eighty-three in the Bay region.

Two years ago, consulting engineers recommended that San Francisco cart its refuse 200 miles out into the desert, over the Western Pacific Railroad tracks, where it would be buried. The outlying county was willing to take the garage - for a fee. In attempting to develop the solid wastes rail haul concept into a regional system, the investigators established six objectives allowing for a) no environmental impairment; b) emphasizing resource conservation; c) inclusion of all solid waste streams; d) flexibility to include future technological developments; e) region-wide organization; and f) least net cost.

Rail haul and burial did not satisfy most of the above objectives. Therefore, the regional system being developed envisions the use of composted solid wastes for rebuilding of agricultural soils while reclaiming metals and glass. The regional plan emphasizes barge haul of shredded, separated material to below-sea-level agricultural islands for compositing and land building. A demonstration program including six cities is now being developed.

3.0080, OPTIMIZATION OF SEWER SYSTEMS

S.A. MILES, Damas & Smith Limited, *Don Mills, Ontario, Canada*

Parameters in the layout, design and construction of storm and sanitary sewer systems are defined. These include water conditions, soil and rock strata surface topography and outlet conditions. Design algorithms for sanitary and storm systems by empirical and rigorous methods are programmed. An optimization procedure is developed using heuristic methods, to generate the sewer system design of minimum cost on the basis of a set of bid unit prices.

Document provided by Highway Research Information Service.

SUPPORTED BY U.S. Dept. of Transportation - Public Rds.

3.0081, SEWER SYSTEM DESIGN, CONSTRUCTION AND MAINTENANCE PRACTICES AND EVALUATION

S.A. MILES, Damas & Smith Limited, *Don Mills, Ontario, Canada*

A survey of 36 municipalities in Ontario provides the basis of an evaluation of current sewer system design and operation. The data represents systems in various sizes of municipalities, and covers about 50 percent of the provincial population. A tabulation of results indicates an apparent wide range of design criteria and operating practices. An interpretive assessment of these findings in terms of costs and equivalent benefits for a model city is demonstrated. The annual cost savings by application of rigorous system design methods is estimated and compared with the increased engineering costs necessary for this type of design procedure.

Document provided by Highway Research Information Service.

SUPPORTED BY U.S. Dept. of Transportation - Public Rds.

3.0082, APPLICATION OF DYNAMIC AND LINEAR PROGRAMMING TO URBAN DEVELOPMENT

R.W. SMITH, Damas & Smith Limited, *Don Mills, Ontario, Canada*

Urban development depends on the extension of distributive services - sanitary and storm sewers, watermains and streets. The optimal sequence of projects in each distributive service sector over a planning period is constrained by limiting service levels adopted, capital resources available and tax levels permitted. Capital and tax resources are related to the assessment of socio-economic activities serviced by the extended sewers, watermains and street systems. Dynamic programming in four dimensions, equivalent to successive 5 year programs over a 20 year macro-planning period, modified by a detailed initial 4 year program, is utilized to determine optimal sequence of projects. Output includes tax rates, capital resource use, and assessment formation. The procedures are applied to a small urban system of a town of 15,000 population.

Document provided by Highway Research Information Service.

3.0083, AERATED LAGOONS & ANAEROBIC REACTORS - A FIELD & LAB STUDY OF THEIR EFFICIENCIES & DESIGN PRINCIPLES IN SEWAGE TREATMENT
C.R. FORSBERG, Univ. of Saskatchewan, School of Engineering, *Saskatoon, Saskatchewan, Canada*

(a) Proposed Research: To study an aerated lagoon at Moose Jaw and an anaerobic reactor to be constructed in the University's temperature-controlled laboratory lagoon cabinet.

(b) Objective: To explore the possibility that the first compartment of two or more anaerobic cells in series may advantageously be converted to a mixed anaerobic reactor. Limitations in use from the health and nuisance standpoints would receive special attention.

SUPPORTED BY Canadian Government - Ottawa

3.0084, DEVELOPMENT OF A SIMULATION MODEL OF THE VANCOUVER REGION
M. GOLDBERG, Univ. of British Columbia, *Vancouver, British Columbia, Canada*

This grant will support the development of a simulation model of the Vancouver region that will analyze the economic, ecological, social, and political consequences of different development plans for use by city and regional officials.

The project is an outgrowth of a model developed by university faculty and students, under an earlier grant, that explored the effects of carrying development schemes on recreational land use of the Gulf Islands off the Vancouver coast. The city of Vancouver and the Vancouver Regional Planning Commission, along with the university, are also contributing funds to the project.

Drs. Michael Goldberg and C. S. Holling, co-directors of the study, will be aided by a group consisting of three university representatives, three from the city of Vancouver, one from the region, and two graduate students. Submodels on pollution, waste disposal, transportation, and recreation and open space will also be developed. The project has been endorsed by several Canadian agencies, including the Science Council of Canada which is particularly interested in the development of simulation models for urban environmental planning.

SUPPORTED BY Ford Foundation - New York, N.Y.

3.0085, ANAEROBIC TREATMENT OF ANIMAL WASTES
W.K. OLDHAM, Univ. of British Columbia, *Vancouver, British Columbia, Canada*

The purpose of the research is to determine, on a laboratory scale, the effects of various parameters on the treatment efficiency obtained during anaerobic decomposition of animal wastes. These parameters will include antibiotic concentrations in the waste, nutrient concentration in the waste, detention time, temperature, source and strength of waste, and effects of mixing. The need for controlled application of the anaerobic treatment process to decompose waste animal organics is becoming more important as the number of large-scale, concentrated, raising facilities increases.

3.0087, TECHNIQUES FOR IMPROVING THE AMOUNT AND EFFICIENCY OF OXYGEN INCORPORATION INTO RAPID-RATE BIOLOGICAL WASTE TREATMENT SYSTEMS
C.C. WALDEN, Univ. of British Columbia, British Columbia Res. Council, *Vancouver, British Columbia, Canada*

This research will examine techniques for improving oxygen transfer into water and into biological oxidizing systems. Increasing the driving force for oxygen transfer by use of hydrocarbons with high oxygen solubility will be attempted and the effect of dispensing agents in reducing bulk viscosity will be evaluated. Possible effect of these agents on the rates of rapid oxidizing activated sludge systems will be examined. Oxygen transfer in present waste treatment systems is limiting; improved techniques will reduce operating costs and enhance efficiency.

SUPPORTED BY Canadian Government - Ottawa

3.0088, COMPUTER SIMULATION AND DESIGN OF TREATMENT INSTALLATIONS FOR DOMESTIC SEWAGE
P.L. SILVERSTON, Univ. of Waterloo, *Waterloo, Ontario, Canada*

Summary of Project: a) Derivation of mathematical models for waste treatment unit processes and operations, programming of the models in the framework of a process oriented executive program to yield a computer program which simulates the operation of a waste treatment plant or which provides design parameters for a treatment plant. b) The intent of the research is to develop a low cost, easy to use tool for optimum design of waste treatment facilities on the optimization of existing facilities. c) The relation to the health field is through the public health activity. Large amounts of money are spent annually on waste treatment facilities. Objective of research is to get maximum results from this expenditure.

SUPPORTED BY Canadian Government - Ottawa

3.0089, AERATED SEWAGE LAGOON INVESTIGATION - BOISSEVAIN
E.H. BALCHEN, Canadian Dept. of Natl. Health, *Winnipeg, Manitoba, Canada*

(a) The Proposed Research: To investigate operating efficiency of aerated sewage lagoon, followed by short-term detention lagoon.

(b) The Objectives, briefly: To determine the practicality of this new method of aeration.

(c) Relation to Health Field: To determine whether or not the proposed aeration system will be effective and safe for use as a general method of sewage treatment.

SUPPORTED BY Canadian Government - Ottawa

3.0090, EVALUATION OF THE APPLICABILITY OF AERATED LAGOONS FOR SEWAGE TREATMENT ON THE CANADIAN PRAIRIES
A.R. PICK, Metrop. Corp. of Gr. Winnipeg, *Winnipeg, Manitoba, Canada*

(a) The Proposed Research: To assess and compare with reference to conventional facultative lagoons and the activated sludge process, the effectiveness of three available methods of aeration of sewage in lagoon: (i) bubble tube diffusion (ii) surface aerators (iii) air gun aeration (iv) Parallel systems comprised of a conventional faculative lagoon, lagoons with bubble tube diffusion lagoon with surface aerators and an aerated lagoon with air gun diffusion will be placed in services for a period of two years.

(b) The Objectives, briefly: The efficiency of treatment and operating economics of three aeration systems for sewage lagoons will be defined. The results will be compared with those for an operating activated sludge plant and the conventional sewage lagoons. The appropriateness of the design criteria will be investigated.

(c) Relation to Health Field: To establish an efficient and economic treatment system to abate pollution.

3.0091, WASTE COMPOSTS AS CHELATING AGENTS IN PLANT NUTRITION
W.L. LINDSAY, Colorado State University, School of Agriculture, *Fort Collins, Colorado* 80521

3. SOLID WASTE MANAGEMENT

During decomposition of organic wastes in soils, chelating agents are found that increase the solubility and availability of certain plant nutrients. The beneficial effects of garbage composts and sewage sludge for correcting zinc and iron deficiencies have been well demonstrated. The purpose of the proposed study is to identify the soluble chelating agents that form from decomposing organic wastes in soils. Various organic wastes including sewage sludge and garbage composts will be incubated with soils. Water-soluble extracts will be removed periodically and fractionated by chromatographic methods by using Sephadex columns. Functional groups capable of forming metal complexes with iron and zinc will be labeled with 65Zn and 59Fe. Infrared adsorption and chemical analyses will be used to identify the functional groups responsible for the chelation of metal ions. Stability constants of the metal chelates will be measured and related to the beneficial role they play in plant nutrition. Hopefully the findings will provide direct evidence of how organic wastes aid in solubilizing and transporting insoluble nutrients to plant roots.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0092, CATTLE FEEDLOT WASTE AND AIR AND WATER POLLUTION

S.M. MORRISON, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00076)

OBJECTIVE: Determine basic factors involved in environmental pollution by cattle feedlots; feedlot design and operation for minimization of environmental contamination; modifications of manure decomposition; engineering procedures for handling large volume of animal waste; economical uses of animal manures.

APPROACH: The characterization of the microbial flora in manure at varying stages of decomposition will be done in the field and in laboratory. Attempts to modify the bio-degradation process by enrichment techniques (adjust C:N ratio, adding trace elements). By use of air sampling and vapor phase chromatography the volatiles most responsible for air borne 'contamination' will be classified. Bio- degradation modification will be followed in same manner. The hydrology of feedlot runoff and the factors controlling it, including the biological and chemical constituents of the runoff, will be studied. Modifications of the lot design and operations will be experimentally assessed. Ground water contamination will also be evaluated.

PROGRESS: Studies were conducted to define the role of feed supplement antibiotic residues in modifying the decomposition of feedlot wastes. Bioassays of fresh feedlot manure showed 14 mug chlortetracycline while after ageing in the pens there was 0.34 mug per gram of manure. Two groups of three animals each were used in a controlled experiment - one group only getting antibiotic feed supplement (70 mg/head/day). The antibiotic supplementation reduced the 5 day BOD by 28%, an effect on the microorganisms or on the manure constituents. There is indication that the microflora of manure and the manure constituents are modified and that antibiotic reduces the biodegradability of the animal wastes. Studies were completed on several aspects of feedlot runoff: five day and ultimate BOD values, temperature effects, COD, inorganic and organic constituents, redox potential, foaming coagulation characteristics, the modified dimensionless hydrograph of overland flow, surface storage, equilibrium runoff rates, concentrations of BOD, alkalinity, and conductivity; CO(2); settleable suspended solids; volatile solids (related to BOD); and inorganic dissolved solids.

SUPPORTED BY Colorado State Government

3.0093, MANAGEMENT OF ANIMAL WASTES AND FEEDLOTS TO AVOID SOIL AND WATER POLLUTION

F.G. VIETS, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Fort Collins, Colorado* 87101 (SWC-026-DFC-7)

OBJECTIVE: Discover chemical, microbiological, and physical principles, and engineer systems for the effective disposal of animal wastes and management of cattle feedlots so that the combination of manure, urine, and precipitation will not pollute or eutrophy surface ground water, and air.

APPROACH: Laboratory and field studies are conducted to determine: The relation of runoff, deep percolation, and evaporation to precipitation and water in excreta on different slopes, soil site conditions, and densities of animals; the kinds and rates of chemical transformations occurring between the surface and water table; the role of microorganisms in these transformations and the persistence of the common microbial pollution indicators under different management systems; develop systems for better control of the pollutional hazards of concentrated animal and poultry feeding operations.

PROGRESS: Two commercial feedlots have been instrumented to evaluate the various components of the hydrologic and chemical balance. Data collected from automatic vacuum lysimeters, runoff sampling equipment and a climatic station indicate that the weighted mean percolation below 40 inches was 1.3 cm. during a 156-day interval, or 0.008 cm. per day on a flat site. Percolate represented only 3.4 percent of the total water delivered to the lot. Percolation on the sloping site was much less than on the flat site, with only 0.011 equivalent (1.2 x 10 cm. per day). A total of 2.49 cm., or 19.2 percent of the precipitation left the site as surface runoff. Chemical analyses of the percolate samples showed a weighted mean NO(3)-N concentration of 865 p.p.m. at the sampling depth (40 inches) for the level site. Determinations were made on total organic carbon and on the carbohydrate content of soil profile segments from beneath feedlots and closely adjacent farmland. High organic carbon and carbohydrate contents were found in the surface inch or so of feedlot soils, but this material did not appear to move into the deeper profile. BOD determinations made on feedlot and cropland samples invariably gave low values of oxygen consumption, and they too failed to distinguish between subsoil core segments of feedlot and non-feedlot origin.

SUPPORTED BY U.S. Dept. of Agriculture

3.0094, DISPOSAL OF LIQUID INDUSTRIAL WASTE

C.A. JAWORSKI, James S. Minges & Associates, *Farmington, Connecticut* 06032

This project is funded under the auspices of the Connecticut Research Commission.

This project was initiated by the Research Commission at the request of industrial firms in Bristol, in order to determine the feasibility of a community-wide system for the disposal of liquid industrial waste. It was set up as a systems analysis of all alternatives, so that the results might also be useful to other industrial communities in the state, especially those having a large number of metal working firms.

The study was carried out with the full cooperation of the 23 firms in Bristol that produce liquid industrial waste. A separate survey was made of the problem of disposing of waste crankcase oil.

Three broad alternative approaches to the problem were selected for evaluation after a comprehensive review of all known methods of treating liquid wastes, oils and sludges. The alternates evaluated were: A. Centralized combined sanitary and industrial wastes treatment system. B. Centralized separate sanitary and industrial wastes treatment systems. C. Individual industrial waste treatment systems.

The recommended approach for Bristol is a variation of Alternate C in which the sludge from the individual waste treatment facilities would be dewatered in a centralized facility and waste oil would be incinerated in a centralized system. The effluent water from the individual treatment facilities and from the centralized sludge treatment facility would meet the requirements of the Water Resources Commission for flow into the Pequabuck River.

The report points out that different conditions in other communities might favor one of the other alternates.

Attention was given to the possibility of recovering valuable by- products from the waste disposal system. It was concluded that such recovery is best handled by each company as a production control function.

SUPPORTED BY Connecticut State Government

3.0095, DESIGN OF OPTIMAL REFUSE STORAGE DEPOSITORY SYSTEM FOR SERVICING MULTIPLE

DWELLING UNIT BUILDINGS IN ECONOMICALLY DISADVANTAGED AREAS

P.G. MEYERS, Meyers Electro Cooling Prod., *Manchester, Connecticut* 06040

The problem of handling refuse has become acute, especially in core-city areas. High population density, improper refuse storage facilities and lack of education in proper refuse handling compound the problem. Health hazards, neighborhood ugliness, resident agitation and considerable city budgets result.

The proposed investigation is to help solve the problem by formulation of an optimally designed refuse depository system for servicing multiple dwelling unit buildings in economically disadvantaged areas. The design should also result in substantial improvement in refuse collection.

Components of the project include interviews of users (building owners, custodians and tenants) to learn of their problems with refuse storage and collection, first hand.

SUPPORTED BY Connecticut State Government

3.0096, TREATMENT PROCESSES - WASTES PUMPED FROM SEPTIC TANKS

J.J. KOLEGA, Univ. of Connecticut, Agricultural Experiment Sta., *Storrs, Connecticut* 06268

The first year of this study (1969-70) emphasized two categories: (1) The characterization of septage in terms of bacteriological, chemical, and physical parameters, and (2) An economic review of the systems under which septage is collected and treated.

The objectives of the second year of this study are: (1) To develop method(s)/systems for treatment of wastes pumped from septic tanks for small communities (i.e., areas in which conventional treatment plants are not available for disposal of these wastes), and to determine the best point(s) of waste introduction into existing sewage treatment plant processes and what, if any, preparatory treatment is desirable. (2) To develop recommendations for the handling and pre-treatment of septic tank wastes in areas where sewage treatment plant facilities are available.

Included in this study will be microbiological aspects and engineering-economic evaluations.

Project completion date: May 31, 1972.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0097, DISPOSAL AND UTILIZATION OF DAIRY AND POULTRY MANURES BY LAND APPLICATION

J.J. KOLEGA, Univ. of Connecticut, Agricultural Experiment Sta., *Storrs, Connecticut* 06268 (CONS00393)

OBJECTIVE: Develop and evaluate disposal and utilization systems for land application of treated and untreated dairy and poultry manure that will minimize pollution of water, soil, and air.

APPROACH: Field lysimeters will be used to study the effects of poultry manure slurry application rates on the levels of BOD/COD, solids, pH, nitrates, chlorides, and manganese. Crop response (corn) will also be evaluated. Three replications will be made of each treatment along with control plots. For part of the data collected, mathematical expressions will be developed for analog computer analysis to evaluate results that might be expected for other application rates not included in the experimental design.

PROGRESS: Three disturbed and three undisturbed lysimeters were constructed for soil conditions classified as fine sandy loam (Woodbridge) with hardpan layer depth at 20 to 30 inches. Lysimeter surface dimensions were approximately 8 x 8 feet. A tile drainage system was installed for each lysimeter along with a centralized sample collection pit. Two disturbed lysimeters 3 feet deep and 22 inches in diameter, were set up for the evaluation of percolate sampling devices developed.

SUPPORTED BY U.S. Dept. of Agriculture

3.0098, WASTE DISPOSAL IN RURAL AREAS

W.C. WHEELER, Univ. of Connecticut, Agricultural Experiment Sta., *Storrs, Connecticut* 06268 (CONS00348)

OBJECTIVE: Measure and analyze thermodynamic, hydraulic, chemical and bacterial parameters prevalent in septic tank systems used for waste (excreta) disposal in rural Connecticut, with emphasis on temperature measurement and its interaction with the other parameters; design and test new septic systems.

APPROACH: Septic tank systems will be instrumented so that temperature patterns can be obtained for all phases of treatment process. Efforts will be made to determine quantity of influent and effluent without disturbing operation of systems. Bacteriological and chemical analysis will be made of influent, tank solution and effluent to determine effectiveness of treatment processes. Laboratory and field installations will be used. Physical properties of the disposal field will be analyzed and correlated to sewage stability and seepage rates. Effluent in draintile and separate tanks will be subjected to supplemental air and effect on aerobic digestive process will be studied. Modified septic systems will be designed, constructed and tested for more effective disposal of agricultural waste materials from poultry flocks, dairy herds and rural residences.

PROGRESS: An analysis of the hydraulic performance of an household waste disposal system was made. The study included both laboratory and field experimentation. Hydraulically speaking, the findings indicated that perhaps existing design recommendation figures could be reduced under certain field conditions; inadequacies in current installation practices for laying field tile and the type of field drain being used, and indicated a relationship of flood routing procedure to the short flow period of a septic tank system. Collection of temperature and water data at one field installation continued. Analysis of soil temperature data obtained from previous years and during the year reported for two 3-month periods showed a cyclic trend comparable to that of air temperatures. Theoretical evaluations were made of the use of heat for septic tank system operation. If emphasis were placed upon the handling of human body wastes, and waste water quantities were reduced, there may be certain instances where heat exchangers could be used at a reasonable cost if water pollution control were the prime concern.

SUPPORTED BY U.S. Dept. of Agriculture

3.0099, SPRAY SYSTEM FOR DAILY REMOVAL OF LIQUID COW MANURE

N.E. COLLINS, Univ. of Delaware, Agricultural Experiment Sta., *Newark, Delaware* 19711 (DEL00133)

OBJECTIVE: Develop equipment needed for daily disposal of liquid manure with a spray system; determine safe capacity of soil to assimilate liquid manure applied daily by a spray system.

APPROACH: The project includes grinding and pumping liquid manure to a field disposal area. Preliminary tests will be conducted to determine most efficient pump and grinder combination and to determine hydraulic characteristics of liquid manure. For field disposal liquid manure will be pumped 1000 feet to commercial sprinklers or other spreading device. Measurements of pollution, odor, insects, and microorganisms will be criteria for measuring effectiveness of disposal area.

PROGRESS: The first objective of the project was completed and a system developed, however, due to staff leaving the second objective was not completed. Since the start of this project a spray system for liquid manure was developed by a manufacturer. This system is sold today and a number of systems are working on farms. The system developed by the University of Delaware was similar to the commercial system. Therefore, it is felt this project should be terminated. Some of the specific results obtained were as follows: A system for spraying of liquid manure was developed. Pumps were capable of pumping a 1 to 1 manure to water mixture; however, a 3 to 10 mixture of manure to water worked best in the system. The 3 to 10 mixture could be moved through a grinder more easily and size reduction was more uniform with this 3 to 10 mixture. The system terminated with a standard 1/4" Rain Bird sprinkler. Metal nozzles will work but the fineness of grind is highly important as the particles will adhere to each other and again form a layer particle. It is advisable to use a rubber nozzle, thus permitting an expansion of the nozzle when it plugs and pressure in the system increases. The increase in the nozzle opening permits larger particles to pass. In all systems some means of removing stones and gravel should be provided. If this is not ac-

complished before the grinder and other equipment the stones will move through the system and damage the equipment.

3.0100, MASS TRANSFER AND CHEMICAL REACTION IN TWO-PHASE FLOW
F.W. RUSSELL, Univ. of Delaware, School of Engineering, *Newark, Delaware* 19711

The basic mechanism of mass transfer and chemical reaction in two phase (gas-liquid) horizontal pipes is to be investigated so that the possibility of using two-phase pipelines for treatment of raw sewage can be evaluated. A model of the process of chemical reaction and mass transfer has been developed and checked for two-phase flow in a horizontal pipe. Experimental work is proposed which will more fully verify the model and allow numerical determination of the key parameters.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

3.0101, OCEAN DISPOSAL OF INDUSTRIAL WASTES
L.L. FALK, E.I. Dupont De Nemours & Co., *Wilmington, Delaware* 19898

The proposed work for the disposal of an acid-iron waste at sea shall be directed: 1. To determine the physical, chemical and biological effects on a marine environment by the disposal of an acid-iron waste in a specified area. 2. To develop a mathematical model suitable for establishing the disposal characteristics of similar wastes in a similar environment. 3. To provide relative costs of various components of a waste barging operation.

Detail: 1. Design, plan, conduct, and evaluate a study project for the disposal of an acid-iron waste in coastal marine waters. 2. Determine and establish items listed in objective 1a and 1b of the proposal. 3. Compare costs with data available in the literature so that barging costs on a ton-mile or other basis can be extrapolated to other barging conditions. In particular, relative magnitudes of barging leasing, barge towing and shore waste storage facilities will be evaluated.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0102, IDENTIFICATION OF LIMITING FACTORS IN THE BIOLOGICAL TREATMENT OF SEWAGE
G.V. LEVIN, Biospherics Research Inc., *Washington, District of Columbia* 20011

The purpose of this contract is to explore the microbiological and biochemical wastewater literature to determine the intrinsic factors which limit the effectiveness of biological treatment of sewage. Comparisons of the fundamental microbial metabolic rates with those achieved in practice will be made. The information gained will be used to identify significant areas in which sewage treatment does not take full advantage of the biological processes. Once these areas are identified, laboratory and pilot plant research programs can be designed to develop improved treatment methods and practices. The information developed will be particularly useful in purifying the input to a mathematical model describing the activated sludge process which is being developed at the Cincinnati Water Research Laboratory.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0103, BIO-MASS DETERMINATION - A NEW TECHNIQUE FOR THE CONTROL OF AERATION SEWAGE TREATMENT PROCESS
G.V. LEVIN, Biospherics Research Inc., *Washington, District of Columbia* 20011

To examine a new method, conceived and developed by personnel of Biospherics Research, Inc. for the rapid determination of bio-mass and to assess the feasibility of applying this method in the control of sewage treatment processes. The proposed method is the firefly bioluminescent assay for microbial adenosinetriphosphate.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0104, ROADSIDE LITTER COMPOSITION
P.E. IRICK, Highway Research Board, *Washington, District of Columbia* 20037

An Ad Hoc Advisory Committee was formed that includes representatives of 29 participating state highway departments, the District of Columbia Division of Sanitation, the U.S. Bureau of Public Roads, the Research Triangle Institute of North Carolina, the Highway Research Board, and Keep America Beautiful, Inc. This committee was responsible for planning and general monitoring of the litter composition project. The general plan called for each participating state to make two litter pickups, 30 days apart, on each of the primary highway study sites selected at random. Using highway mileage data supplied by participating states, study sections were selected by Research Triangle Institute Staff, each study section was 0.2 miles long and covered the full width of the right-of-way. The study data came from a total of two miles of right-of-way in each state. Two forms were completed for each study section after each pickup (1) the section data form provided for the sections geographical.

Document provided by Highway Research Information Service.

3.0105, COMMUNITY ACTION PROGRAM FOR SOLID WASTES MANAGEMENT
UNKNOWN, Natl. Assn. of Counties, *Washington, District of Columbia* 20036

Ten community action guides pertaining to solid wastes management in in ten subject areas are to be developed. Action guides are to be reviewed and revised by representatives of federal, state and local government officials at a National Solid Wastes Workshop. Twenty regional Solid Wastes Management Institutes are to be organized and conducted for discussion and dissemination of the guides.

Document provided by Highway Research Information Service.

SUPPORTED BY National Association of Counties

3.0106, PERFORMANCE EVALUATION OF SOVENT SYSTEM
R.S. WYLY, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

Technical Objective: Report findings as to the performance of the Sovent Single-Stack Plumbing System with loads up to approximately 50 bathrooms.

SUPPORTED BY U.S. Dept. of Commerce - N.B.S.

3.0107, REMOVING TRASH FROM MECHANICALLY HARVESTED SUGARCANE
H.D. WHITTEMORE, Everglades Agric. Expt. Sta., *Belle Glade, Florida* 33430 (308-041-C705)

OBJECTIVE: Develop methods of removing tops, leaf trash, soil, and other foreign material from mature sugarcane.

APPROACH: Experiment with methods of snapping the tops from the mature cane pieces. Develop systems for removing trash at every point in the harvesting and handling process that is feasible. If open field burning is prohibited, find ways to remove dry trash from the ground to improve operator visibility. Determine the best method of pneumatic cleaning and trash disposal. Devise methods of positively pulling green trash from mature cane pieces and disposing of the trash. Develop cleaning systems that might be incorporated in a harvester with a capacity of 30 to 60 tons per hour.

PROGRESS: No progress reported this period (new project).

SUPPORTED BY U.S. Dept. of Agriculture

3.0108, NEMATODES ASSOCIATED WITH SEWAGE TREATMENT AND THEIR SIGNIFICANCE
W.T. CALAWAY, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-EY-01323)

OBJECTIVE: Not Provided

APPROACH: Not Provided

PROGRESS: During the period of support investigations were carried on, research was done on the use of resin impregnation similar to that used for electron microscopy, sectioning, staining and examining visually. This was done to obtain histological information on structures after it was found that the usually parafin infiltration, sectioning and staining did not yield the information desired. Methods were developed for obtaining serial sections on portions of cover slips. These were than stained at temperatures in the neighborhood of 90 C. Several modifications of the basic fuchsin staining was tried as was regressive staining using gential violet. The publication of a description of Mononchoides changi by Goodrich, Hechler and Taylor has made it necessary to examine the Mononchoides species being described by us in order to find if differences between the two species exist. The species Mononchoides have been reviewed and a monograph discussing all the species known to have been included in this genus or in synonymous genera is in preparation. An amended, more concise description has been written and the members of all previous lists of Mononchoides have been compared with the amended description and with the original writers own diagnosis. This genus has been found to be the predominant diplogasterid in waste treatment.

SUPPORTED BY Florida State Government - Tallahassee

3.0109, ANTI-POLLUTION AND SEWAGE DISPOSAL FOR FLORIDA COMMUNITIES
T.D. FURMAN, Univ. of Florida, School of Engineering, *Gainesville, Florida* 32601

This is a continuing study, renewable annually, of various methods of sewage treatment applicable to the semi-tropical climate of Florida. Special emphasis is directed toward modifications of design standards in order to take advantage of the warm climate and increased sunshine. The use of native filter materials is being investigated. Among the studies which have been conducted is an investigation of the efficiency and degree of treatment provided by intermittent sand filtration as influenced by size and depth of sand as well as the hydraulic and organic loading. A study of lagooning to determine the degree of treatment and efficiency of this method of sewage treatment, using both settled and unsettled domestic sewage at various hydraulic and organic loading rates has also been completed. The ecology of the flora and fauna instrumental in the treatment was investigated.

SUPPORTED BY University of Florida

3.0110, REACTION OF IRON AND ALUMINUM SALTS WITH PHOSPHATE
J.E. SINGLEY, Univ. of Florida, School of Engineering, *Gainesville, Florida* 32601

The proposed study would determine the effect of a number of variables on the reactions of iron and aluminum salts with the phosphate present in effluents from industrial and domestic waste treatment plants. The study would focus upon the determination of the competition of other anions with phosphate for coordination sites on the iron and aluminum ions in solution. The anions to be considered will be hydroxide, sulfate, chloride, nitrate and some organic anions. The kinetics, as well as the equilibria, will be studied.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

3.0111, AEROBIC DISPOSAL OF ANIMAL WASTES WITH CONTINOUS WATER REUSE
R.E. SMITH, Univ. of Georgia, Agricultural Experiment Sta., *Athens, Georgia* 30601 (GEO-03-0370)

OBJECTIVE: Study operating characteristics of system for decomposing animal wastes with continous aeration and mixing of wastes and use of effluent from system for dilution of low moisture animal wastes. Determine design parameters for system of influent waste dilution, feeding rate, detention time, 5-day BOD reduction, and rate of sludge build-up.

APPROACH: Effluent of a laboratory aerobic disposal units will be revised as the diluent of influent animal waste. Will determine if concentrations of any component of animal wastes will be detrimental to growth of requisite microbes. Information will be obtained about optimum input rates, dilution times, BOD reduction, and rates of sludge build-up.

PROGRESS: Research was conducted to determine the effects of a salts buildup on the biodegradation of poultry wastes in a recycling system. The inorganic products liberated upon complete digestion of the wastes was determined, including the specific ions released and the relative amounts of each. Then a graduation of solutions were synthesized by mixing chemicals to give the same constituents as the digested wastes. These synthetic solutions were used to dilute waste samples for aerobic digestion. The digestion rates were measured by periodic BOD tewts and expressed in mathematical form. The conclusion was reached that such systems would operate satisfactorily if sludge wasting is carried out to limit solids buildup.

SUPPORTED BY Georgia State Government

3.0112, PERFORMANCE OF THE INCLINED-PLANE TRICKLING FILTER FOR AEROBIC DISPOSAL OF ANIMAL WASTE
R.E. SMITH, Univ. of Georgia, Agricultural Experiment Sta., *Athens, Georgia* 30601 (GEO-03-0467)

OBJECTIVE: Determine the biological reduction-rate constant as a function of contact time for the inclined-plane trickling filter. Correlate the inclined-plane slope and length and the hydraulic flow rate to contact time for the filter. Develop a mathematical model for the variables of the inclined plane.

APPROACH: Laboratory studies will be used with an inclined-plane trickling filter using diluted poultry waste as influent. Constants for the mathematical model will be evaluated from the operating data of the different plane positions and hydraulic flow rates. The form of the mathematical equation is: $L/L(o)0e$, where L is the remaining BOD in ppm, L(o) is the initial BOD, t is the residence time, and k is to be evaluated for the waste and the system.

PROGRESS:

SUPPORTED BY Georgia State Government

3.0113, DESIGN AND OPERATION CRITERIA FOR AN ANAEROBIC LAGOON FOR SWINE WASTE
R.E. SMITH, Univ. of Georgia, Agricultural Experiment Sta., *Athens, Georgia* 30601 (GEO-03-0472)

OBJECTIVE: Design and construct an anaerobic lagoon for a new 400- animal swine facility at the College Experiment Station. Obtain operating data pertaining to: startup procedure, seepage losses, odor production, solids reduction and BOD reduction. Utilize the findings to construct and operate a field-scale lagoon for the conditions of the Piedmont region.

APPROACH: An anerobic lagoon will be designed to permit measurement of seepage losses and determine the role of sealing in anaerobic lagoon operations. A method of water reuse will be a part of the seepage studies. Data will be taken to study startup and operating procedures for the anaerobic lagoon.

PROGRESS:

3.0114, EVALUATION OF TREATMENT PLANTS BY TRACER METHODS
G.G. EICHHOLZ, Georgia Inst. of Technology, Engineering Experiment Station, *Atlanta, Georgia* 30332 (AT-(40-1)-4156)

Many of the processes used in treatment plants for municipal and industrial wastes can be studied by means of radiotracer methods. As the addition of radioactive tracers may be unac-

ceptable, post-sampling activation analysis with suitable non-toxic materials will be employed. The objectives of the proposed project are two-fold: 1) To select materials and develop methods for studying the mobility and characteristics of particulate tracers and the determination of the tracers, both in dissolved form and attached to very fine particles, that would be suitable for studying and measuring the operating parameters of waste treatment plants. This will involve laboratory tests on the behavior of the tracer materials in various mixing processes and on the competitive interactions in a medium containing finely divided material and agglomerates of varying characteristics. 2) To use these methods to investigate the operating conditions of selected treatment plants to establish the utility and practical limitations of the proposed procedures and to render practical advice and assistance to the plant operators.

SUPPORTED BY U.S. Atomic Energy Commission

3.0115, DIGESTION OF SLUDGES WITH SODIUM CHLORIDE AND SULFATE
R.S. INGOLS, Georgia Inst. of Technology, Engineering Experiment Station, *Atlanta, Georgia* 30332

The primary objective of the projecct is the determination of the cause of sludge digestion failure in the presence of industrial wastes containing several salts at critical concentrations. If sodium chloride plus sodium sulfide are synergistically toxic then a search will be made to find as economical solution to the sludge disposal problem.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0116, SENSORS FOR CONTROLLING THE ACTIVATED SLUDGE PROCESS
R.S. INGOLS, Georgia Inst. of Technology, Engineering Experiment Station, *Atlanta, Georgia* 30332

The project for developing sensors to control the activated sludge process of treating waste water has been funded (in the past) by a contract with the City of Atlanta and is currently supported by Georgia Institute of Technology. The city needs a new water pollution control facility using the Activated Sludge Process for the waste water from the Peachtree Creek drainage basin which will treat 4 cubic meters per second on the average.

The activated sludge process depends on microorganisms for its effectiveness in reducing the pollution load (effect) on the Chattahoochee River. The process which has several operating variables treats a waste water with variable characteristics. At times the effluent will have to be more highly treated than at other times. Because of (1) the large number of variables and (2) the time required to obtain laboratory data to assay the variables and (3) the added cost of operating the process at its maximum effectiveness and (4) the non- professional training of the available personnel and (5) the possible economy of using computers, the decision was made to provide computer control for the Peachtree Creek Plant. All the necessary sensors were not available for computer input and the electronic circuits are necessary to convert all the sensor circuits to digital form.

This project has developed two new sensors and the electronic conversion circuits for a digital printout device. The two new sensors include an oxygen uptake rate apparatus and a sludge concentration reader.

SUPPORTED BY Georgia Institute of Technology

3.0117, IMPROVED PROCESSING OF HAWAIIAN FRUITS
J.E. BREKKE, Univ. of Hawaii, U.S.D.A. Fruit Laboratory, *Honolulu, Hawaii* 96822 (W3-1-157)

OBJECTIVE: Develop new and improved processes for preparation of stable and high quality concentrated tropical fruit products.

APPROACH: Process Hawaiian fruits (guava, papaya, passion fruit, pineapple) into concentrates and dehydrated pieces and powders. Study best means to recover and add back volatile flavors. Determine composition of volatile components. Develop new juice blends, jams and jellies, and uses for dehydrated pieces. Develop methods for concentration, drying, or reuse of wastes. Investigate recovery of food or feed values from wastes.

PROGRESS: The stability of guava puree concentrate with added antimycotic agents was determined at 45 F.; no microbial spoilage but some quality deterioration was observed in 5 mos. storage. Heat inactivation of enzymes in guave puree for frozen storage did not appreciably enhance its stability. The carotenoid pigments in pink- fleshed guava were shown to be lycopene (096%), beta-carotene (2%), unidentified ( ). Non-volatile organic acids in papaya and guava were identified and determined quantitatively. A continuous-flow evaporator was used for production of high-quality concentrates of guava, papaya, pineapple and passion fruit juices and purees. Further exploratory work was done on evaluating quality of concentrates by dilution and sensory evaluation. Quality and stability of frozen mango slices were determined. Osmo-Vac dried bananas, various fruit beverage products, and samples of banana puree were prepared in cooperation with fruit processing companies to demonstrate new products.

3.0119, SORPTION ISOTHERMS OF PHENOL ON ION EXCHANGE RESINS
J.W. CHEN, Southern Illinois University, School of Engineering, *Carbondale, Illinois* 62901

Phenol is a troublesome pollutant from industrial wastes, it cannot be removed by biological treatment easily. Ion Exchange Resins are proposed as potential adsorbents to remove phenol because their selectivity and capacity.

Five different resins were screened. It was found that both IR 45 and IR 401 resins are excellent adsorbents for phenol. Sorption isotherms of these two resins at different pH and temperatures are investigated.

SUPPORTED BY Southern Illinois University

3.0120, NATIONAL CONFERENCE ON SOLID WASTES DISPOSAL SITES
L. WEAVER, Amer. Public Works Assn., *Chicago, Illinois* 60637

This application for a research grant is to support a Conference, nationwide in scope, to stimulate and assist State and local governments to formulate action programs which would lead to the acquisition, development, operation and maintenance of solid wastes disposal sites to meet their demonstrated needs, both immediate and on a long range basis, and consonant with overall community development requirements.

Research is proceeding on various fronts toward meeting the technological challenge of solid wastes disposal. The results of research on methods of managing solid wastes must be supplemented with research to develop workable abd acceptable programs to provide the answers to where wastes which are not salvaged or recycled can be processed and sequestered in a manner harmonious to environmental requirements. Solid wastes disposal encompasses elements that have an effect on the total environment. These include economic, social and political considerations associated with air and water pollution and other environmental health concerns. The multiplicity of governmental jurisdictions in urban areas responsible for the continued operation of thousands of sub-standard disposal facilities and sites makes it imperative that a comprehensive, workable program of action be developed to stimulate and guide the application of this research.

It is proposed that a National Conference be held in the spring of 1971 involving personnel from local, State and the Federal government, universities and private enterprise. The objective is the development of a series of recommendations which State, local, and Federal officials can utilize to formulate action programs. A Proceedings of the Conference will be published.

3.0121, A METHOD OF MANURE DISPOSAL FOR A BEEF PACKING OPERATION

W. WILCOX, Illinois Packing Company, *Chicago, Illinois* 60609

It is proposed to engineer, construct and install a fluidized solids incinerator plant in the plant of Illinois Packing Company, a beef slaughter house in Chicago, to demonstrate an efficient disposal proces for paunch manure from the live cattle.

The plant will have the capacity to handle five tons of feed per day. The incineration process consists of a feed bin, a concentrating conveyor and a fluidized solids incinerator tower operating at approximately 1400 degrees F. The heat of combustion of the process is sufficiently utilized to minimize fuel costs.

The discharge streams from the plant consists of water condensate, oxides of combustion ad sterile ash. It is expected to conclusively demonstrate that the process is a sound approach to this industrial waste disposal problem.

The operation of the plant will contribute valuable operating information and experience in the area of animal solids waste disposal.

3.0124, DEVELOPMENT OF A MATHEMATICAL MODEL FOR SEPARATION, COAGULATION AND SEDIMENTATION PROCESS USING ADDITION OF CHEMICALS

W.A. JASIONOWSKI, General American Trans Corp., *Niles, Illinois* 60648

The contractor shall develop a mathematical model for coagulation and sedimentation of activated sludge process effluent using lime or alum as an additive. The emphasis shall be placed, first, on establishing the current state of design procedures for predicting the performance of existing equipment such as the Infilco Densator or Accelator. Next, limitations of current design procedure should be delineated by comparison with data from existing installations.

The limitations of existing design procedures should then be used as a basis for developing improved design procedures or, if necessary, recommending additional experimental programs.

The model shall consist of a set of preliminary design relationships for computing the size of the equipment required, the amount of chemicals and power required, and estimates of both capital and operating and maintenance cost. The performance of the process is expressed by the volume flow and concentration of all important species in the effluent streams from the process as a function of the characteristics of the influent stream and the operating and design conditions should be expressed in mathematical terms.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

3.0125, DEVELOPMENT OF MATHEMATICAL MODEL OF SEWAGE SLUDGE FLUIDIZED BED INCINERATORS

J.D. ZEFF, General American Trans Corp., *Niles, Illinois* 60648

To develop a mathematical model of the incineration of sewage sludge in a fluidized bed furnace. The model will be written in FORTRAN language applicable to an IBM 360/65 computer.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

3.0126, ACTIVATED SLUDGE - BIO-DISC TREATMENT OF DISTILLERY WASTES

J.O. NACK, Amer. Distilling Company Inc., *Pekin, Illinois* 61554

This project involves construction of two biological waste treatment process lines, one utilizing activated sludge treatment, and the other a Bio-Disc system. The Bio-Disc system will be designed to handle 25 percent of the design hydraulic and organic waste load from the American Distilling Plant. An equalization tank will precede the Bio-Disc unit for tempering of pH and temperature peaks. Individual clarifiers will be provided following each biological system. Sludge thickening and dewatering on drying beds are proposed prior to ultimate disposal in a landfill operation.

Significant operational flexibility has been incorporated into the preliminary layout of the treatment facility. Basic investigations will be conducted on a parallel flow pattern. Within this operational framework, a number of factors will be evaluated including effect of ambient temperature; effect of wastewater temperature and pH extremes; effect of the extended periods of zero flow; effect of varying nutrient feed levels; and effect of varying organic and hydraulic loading.

Evaluation of a series flow pattern is also anticipated. In this arrangement, the Bio-Disc system will serve as a roughing biological process, followed by activated sludge polishing treatment.

A complete sampling and analytical program will be conducted to evaluate system performance and economics.

Results of the research program will be compiled in a suitable format for utilization in establishing design and operational parameters for use throughout the industry.

This project was started in June 1970 and will be completed in June 1972.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0127, BIOPOLYMERS AND POLYMER-PRODUCING MICROORGANISMS IN ACTIVATED SLUDGE

L.L. WALLEN, U.S. Dept. of Agriculture, Northern Utilization Res. Div., *Peoria, Illinois* 61604 (N1-1-355)

OBJECTIVE: Investigate biopolymers in activated sludge, determine types of microorganisms responsible for their production, and establish practical conditions for their recovery as a means of improving economics of cereal waste treatment.

APPROACH: Analyze sludge from cereal and municipal waste treatment plants for content of polysaccharides and other polymeric material. Quantitate and characterize other microbial products and components of sludge. Test selected products for possible uses and biological activity. Establish optimum conditions for economic and complete recovery of products with

potential commercial value. Study slime formation by sludge microorganisms in pure culture, and compare polysaccharides thus obtained with those isolated from sludge. Determine optimal conditions for growth of slime-producing microorganisms and for slime production; determine types of bacteria responsible for slime or polysaccharide formation; and determine whether other potentially useful products are formed.

PROGRESS:

SUPPORTED BY U.S. Dept. of Agriculture

3.0128, UTILIZATION OF FLORIDA PHOSPHATE SLIMES

S. VASAN, Internat. Min. & Chem. Corp., *Skokie, Illinois* 60076

Very finely divided wastes are suspended in water during the processing of phosphate rock matrix. These wastes, termed 'slimes', tie up huge quantities of water in slime pond reservoirs. Because of the colloidal nature of the slime it is very difficult to dry the ponded wastes. The water pollution problems which can occur because of this method of phosphate processing and waste disposal are: 1) fouling of fresh water due to seepage from ponds, 2) lowering of the water table due to high water requirements, and 3) sea water encroachment due to a lowering water table. There is also a large and wasteful use of land in the impoundment of these wastes.

The solution consists of using the slimes to produce a large volume product of ceramic materials. Preliminary market studies indicate a substantial demand for structural clay products. Experimentation by the IIT Research Institute has shown that clay-type bodies may be made from slimes using standard kiln techniques. Such bodies, such as brick & ceramic tile, have considerable potential in areas such as Florida which have shown trends toward accelerated building & construction in the nex few years. This test coupled with the results of previous experiments involving the use of phosphate slimes, indicates the potential for utilizing large volumes of waste materials. If this market can be realized, considerable water may be released from the slime ponds for reuse as well as minimizing the pollution aspects of processing phosphate ore.

3.0129, CHLORINATION OF SEWAGE EFFLUENTS

R.L. EVANS, State Water Survey, *Urbana, Illinois* 61801

As part of an investigation to relate chlorine dosage, bacterial kill, and chlorine demand with the chemistry of various types of sewage effluent, the use of chlorine gas versus hypochlorite will be explored. Efforts will also be directed toward defining the major chlorine reducing substances in sewage effluents, the rates of reaction, and the relative lethal activity of definable chloramines. A principal adjunct to the investigation will be an effort to use MF techniques that produce comparable coliform counts with the MPN method.

SUPPORTED BY Illinois State Government - Springfield

3.0130, CHLORINE CONTACT TANK DESIGN

V. KOTHANDARAMAN, State Water Survey, *Urbana, Illinois* 61801

The current methods of designing chlorine contact tanks for the partial disinfection of sewage effluents have many shortcomings. Field experience suggest short circuiting, solids accumulation, and maintenance problems all resulting in inefficient and, consequently, ineffective operation. A study, employing a hydraulic model, is being undertaken to develop a rational design for chlorine contact tanks using some of the techniques developed in sewage treatment technology. Tracer studies using Rhodamine B dye in a hydraulic flume will be used for positioning and evaluating control appurtenances. Once design criteria have been selected the efficacy of the concept will be tested using fuller's earth; finally it is planned to test the model in the field with an on-line sewage treatment facility.

SUPPORTED BY Illinois State Government - Springfield

3.0131, BIOLOGICAL METHANE FORMATION

M.P. BRYANT, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-35-0364)

OBJECTIVE: Obtain fundamental ecological, nutritional, and biochemical information on the methanogenic bacteria that can be applied to a general understanding of the process of the anaerobic degradation of organic matter in important systems such as sewage and rumen fermentations.

APPROACH: The quantitatively significant methanogenic bacteria will be enumerated, isolated and characterized. The biochemistry of methane formation will be further elucidated.

PROGRESS: We previously showed that ethanol oxidizing methane bacterial species are in fact symbiotic associations of two species. One is an H(2)-utilizing methane bacterium (M) which reduces CO(2) to methane and the other is an organism such as S organism which ferments ethanol to acetate and H(2) but grows poorly unless M is present to maintain a low partial pressure of H(2). Extracts of S show that it oxidizes ethanol to acetaldehyde via an NAD-linked alcohol dehydrogenase (ADH), and acetate and H(2) is produced via a ferredoxin (Fd)-linked aldehyde dehydrogenase. Extracts contain Fd which is essential for NAD reduction by H(2). The results suggest that S grows in the presence of the methane bacteria since the reoxidation of NADH derived from the ADH reaction requires a low partial pressure of H(2). S contains a formate hydrogenlyase system which requires both NAD and Fd for H(2) formation. The presence of S in an environment allows methane formation from formate by H(2)-utilizing methane bacteria which may not metabolize formate. Attempts to isolate species of bacteria responsible for oxidation of butyrate to acetate coupled with reduction of CO(2) to methane has continued unsuccessful but isolation of two new species of methane bacteria that utilize H(2) but not butyrate from butyrate enrichments of rumen contents and sludge suggests that methane formation from butyrate requires a symbiotic association of two species as shown in ethanol fermentation. Attempts to isolate butyrate oxidizing bacteria on anaerobic agar media containing heavy lawns of H(2)- utilizing methane bacteria are under way.

SUPPORTED BY Illinois State Government - Springfield

3.0132, ANIMAL WASTE MANAGEMENT WITH POLLUTION CONTROL

D.L. DAY, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-10-0375)

OBJECTIVE: Further develop animal waste management systems to (1) collect, transport, manage; (2) treat and condition, (3) utilize and dispose of wastes; and (4) analyze and integrate systems from 1, 2, and 3 in a manner that minimizes pollution of air, water and soil and is compatible with efficient agricultural production.

APPROACH: Will use in-the-building oxidation ditch for waste treatment. Designs for floors and pens will be refined to eliminate buildup of waste and to reduce odors and gases. Tolerance levels will be determined by testing pigs in small chambers in which atmospheric components can be controlled and varied over desired ranges.

PROGRESS: The in-the-building oxidation ditch eliminates objectionable odors from manure pits and reduces pollutional value of waste by about 90 percent.

SUPPORTED BY U.S. Dept. of Agriculture

3.0133, HYDROGEOLOGY OF SOLID WASTE DISPOSAL SITES

G.M. HUGHES, Univ. of Illinois, Graduate School, *Urbana, Illinois* 61801

The objectives of this project are to investigate hydrogeologic environments in northeastern Illinois that are being used for shallow solid-waste disposal, and to evaluate the factors that control ground- water movement of refuse leachate in these environments. Criteria are sought to judge the suitability of proposed disposal sites not only in glaciated areas, such as northeastern Illinois, but in many other areas as well.

Existing landfills are being studied, and the investigation is proceeding by: (1) drilling by wash boring or with hollow-stem augers to determine the character and sequence of deposits; (2) installation of piezometers to define fluid potential distribution and the ground- water flow system; (3) sampling of the ground water for chemical analysis; and (4) a monitoring program of the piezometers to determine seasonal variations of the flow system.

SUPPORTED BY University of Illinois

3.0134, LIVESTOCK WASTE MANAGEMENT

W.H. LUCKMAN, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-12-0316)

OBJECTIVE: Develop procedures for the removal, reduction or de- toxification of pesticide residues and conversion products in agricultural commodities. Develop or improve methods for determining pesticide residues in agricultural commodities in marketing channels.

APPROACH: Modifications of present processing techniques to removal or reduce toxicity of chemical residues in food products (with emphasis on soybeans). Development of new chemical or non chemical detection methods. Improved instrumentation for analysis of chemical residues. Analysis of food samples to evaluate techniques.

PROGRESS: The outstanding achievement reported at the last NCM-37 meeting was the development of a method for partitioning extracts on a 2" x 8' strip of glass microfiber for final cleanup before analysis. Acetonitrile extracts or other extracts are applied in a one-half inch band across the width of the fiber strip and partitioning solvents such as pure acetonitrile is allowed is allowed to move by capillarity over the treated zone. Botanicals, synergists, and pesticides move with the solvent front away from the fat, oils, or waxy residue. The portion above the residue band is cut off and extracted with hexane or some other appropriate solvent. Meat, milk, or vegetable material contaminated with .01 ppm organophosphates, carbamates, pyrethrins, piperonyl butoxide, and others have been processed in this way for analysis with high recovery values (80-95%). This will be a valuable method of cleanup in research on the isolation of many organic compounds. The study of aldrin and heptachlor residues in Ill. soybeans has been discontinued since our work has to a considerable extent brought about the needed federal action in regulating the use of these pesticides. Initial studies with furadan have shown that its toxic glucaronate can be found in most plant parts when soybeans, radishes, and turnips are grown on soil treated at a dosage of 20 lb. per acre. We have no future plans for this project because of the June termination date. Certain aspects of this project, particularly methodology, can be utilized within the scope of the NC-85 project.

3.0135, DEVELOPMENT OF A DEVICE FOR DISCHARGE MEASUREMENT WITHIN A SEWER PIPE

H.G. WENZEL, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

The objective of the research is to develop a device which is capable of measuring unsteady discharge within a sewer pipe under both open channel and full flow conditions. The increasing need for drainage data in urban areas points out the need for such a device.

The funding will permit analytical studies to determine the optimum geometry and theoretical rating curves for the device. Various flow conditions will be considered. A laboratoy demonstration model will be constructed and tested to verify the computations and to illustrate the operation of the device under various flow conditions.

SUPPORTED BY University of Illinois

3.0136, USE OF ALGAE, ALGAE-PROTOZOA, AND ALGAE-BACTERIA CULTURES IN SEWAGE TREATMENT

S.V. GANAPATI, Univ. of Baroda, *Baroda, India* (908-034-B703)

OBJECTIVE: Reduce cost of rural community sewage treatment and disposal through optimum algal-protozoal and algal-bacterial symbiotic balances.

APPROACH: Evaluate various species of photosynethetic algae from sewage in and around Baroda and Ahmedabad for oxygen liberating capacity and resistance to zoo-plankton predators. Select most suitable species and determine optimum conditions for growth and development. Treat selected species to develop mutants and evaluate with respect to oxygen liberation and sewage purification. Grow selected algae species with Vorticella Epistylis and other protozoa. Vary environmental conditions to determine optimum. Make similar studies of algal-bacterial symbiosis. Further evaluate promising laboratory results in outdoor tank pilot plant.

PROGRESS: Several types of bacteria were found to utilize the soluble organic and other nutrient substances in sewage by oxidative assimilation in 4-7 days. Chlorella vulgaris, Oscillatoria obscura and Oscillatoria chalybea carry on antagonistic symbiosis while Scenedesmus quadri cauda, Nostoc pyriformis and Aulosira fertilisima carry on mutualistic symbiosis. Final purification takes place and results in a considerable reduction in turbidity, BOD (corresponds to relative stability), organic matter, ammonia nitrogen and phosphates during 7-28 days as a result of endogenous respiration. Chlorella vulgaris is a very fast-growing algae in sewage producing a comparatively high level of chlorophyll, dissolved oxygen and a phenolpthalein alkalinity. As a result of the latter, almost all of the ortho-phosphates and ammonia nitrogen are removed from the medium.

3.0137, EFFECT OF IRRADIATION ON THE MICROECOSYSTEM OF SEWAGE

C. RAMSKRISHNAN, Univ. of Baroda, *Baroda, India*

Effect of irradiation on the microecosystem of sewage (part of a coordinated programme of research on the study and environment of biosphere resources).

SUPPORTED BY Intl. Atomic Energy Agency - Austria

3.0138, LIFE CYCLE DAIRY HOUSING, MANAGEMENT AND BEHAVIOR

J.L. ALBRIGHT, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01407)

OBJECTIVE: Investigate least-cost rations for cattle and ascertain the effect of different types of housing, materials handling and milking schemes upon sanitation, health, cow behavior, production levels and economic returns.

APPROACH: With the cooperation of interested groups, data will be collected, analyzed and forms developed for electronic computers. Through the use of forage analysis combined with linear programming techniques, least-cost rations that are acceptable, palatable and economical for cattle will be determined. Various housing, manure handling and disposal, and feed handling systems will be evaluated at three locations in Indiana that are under the direct management of Purdue personnel. Field studies in conjunction with regulatory agencies to determine sanitation, labor efficiency and economics will be studied. Males, representing a large and often unwanted by-product of the dairy industry, will be fed various rations ranging from predominately forage to all-grain. Attempts will be made to alter the color of the meat from certain traditional dairy breeds. Carcass evaluation will be done under project 1312 (NC58).

PROGRESS: Dairy herd management research needs were categorized into 10 important areas. Studies on methods of handling dairy manure continued. A deep (20 ft.) lagoon with a capacity of 175,000 cu ft. has been excavated. To reduce the cost of bedding and its removal, various permanent and minimum bedding materials were used in free stalls. Under winter conditions, pit-run gravel and either sawdust or chopped corn stover was satisfactory for yearling heifers. Blacktop was superior to wood. With permanent bedding (rubber mats or Tartan 3M indoor track mats) there was an increase in udder irritation and mastitis in first calf heifers. Type of housing, free stalls or stanchion barn, was not related to incidence or severity of mastitis. Dipping teats for 18 months in an iodine solution after milking was associated with a small decrease in udder irritation and no difference in clinical mastitis as compared to not dipping after milking.

3. SOLID WASTE MANAGEMENT

SUPPORTED BY Indiana State Government

3.0139, WASTE TREATMENT FOR AN INDIVIDUAL HOME WITH REUSE OF THE WATER

D.E. BLOODGOOD, Purdue University, School of Civil Engin., *Lafayette, Indiana* 47907

A system consists of a 300 gallon spherical fiber glass tank with nylon bag occupying about 2/3 of the tank volume. Aeration of the bag contents is continuous. Water from the tank is put under pressure, passed through an activated carbon filter and used to supply a conventional flush toilet.

SUPPORTED BY Purdue University - Lafayette, Ind.

3.0140, CONTROL OF FLIES AND OTHER INSECTS ASSOCIATED WITH SWINE PRODUCTION WITHOUT INSECTICIDE

A.C. DALE, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (033201670115)

OBJECTIVE: Measure relative effectiveness of four systems of swine housing and waste disposal for control of fly and other insect propagation without insecticides.

APPROACH: Compare the following four systems of swine housing and waste disposal. Type (A) is an open-front, shed-type with concrete floored front, types (B) and (C) are encolsed houses with partially slotted floors over pits, but with different methods of waste disposal, and type (D) is an enclosed house with total floor slotted over lagoon. In the type(A) house, the manure and bedding is removed weekly; in the type(B) house, the waste is discharged into a septic tank and lagoon; in the type (C) house, the waste is discharged into a holding tank and subsequently spread on adjacent land; and in the type (D) house, the waste is discharged into a lagoon which extends outside the house.

PROGRESS: Four types of swine housing and waste disposal were studied. Type (A) an open-front, shed-type house with concrete floored front, types (B) and (C) enclosed houses with partially slotted floors over pits, but with different methods of waste disposal, and type (D) an enclosed house with total floor slotted over lagoon. In the type (A) house, the manure and bedding were removed weekly; in the type (B) house, the waste was discharged into a septic tank and lagoon; in the type (C) house, the waste was discharged into a holding tank and subsequently spread on adjacent land; and in the type (D) house, the waste was discharged into a lagoon which extends outside the house. Fly populations in type (B) and (C) houses were slightly lower than those in type (D) and substantially lower than in the type (A) house. Mosquito larvae were found in the unscreened lagoons of the type (D) house, but no larvae survived in the septic tank lagoon of the type (B) house.

SUPPORTED BY U.S. Dept. of Agriculture

3.0141, LIVESTOCK WASTE TREATMENT AND DISPOSAL

A.C. DALE, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01631)

OBJECTIVE: Determine effect of aeration on odors and decomposition of wastes. Evaluate disposal of wastes by aerated lagoons and irrigation. Observe effects of oxidation ditches on wastes. Determine the decomposition of wastes by anaerobic and aerobic treatment.

APPROACH: Laboratory studies will be made to find the effect of temperature, time, size of particle, loading rates and aeration on decomposition of wastes. A field trial of an aerated lagoon and irrigation system will be set up to evaluate this method for returning wastes to land. Oxidation ditches at the Purdue Swine and Dairy farms will be monitored to evaluate feasibility for treating and disposing of wastes. Set up a laboratory study using an anaerobic chamber followed by an aerobic chamber to find how completely solids in livestock wastes can be decomposed.

PROGRESS: The effect of 4 loading rates at 24 C and 4 C was determined on aerobic decomposition of dairy cattle manure. These loading rates were 9, 12, 15, and 18 grams of dry matter to 4 liters of untreated ground water in aerated chambers. Relations of temperatures 35 F, 45 F, 55 F, 65 F and 75 F to the rate of decomposition of volatile solids in dairy cattle manure was determined. A 74-day experiment was conducted at these temperatures. A reduction of over 70% of the volatile solids was obtained in highest temperature chambers. Settling characteristics of the aerated manure were also determined during the experiment. Other phases on the decomposition of dairy cattle manure are: effect of particle size on decomposition rates, effect of antibiotics on decomposition of dairy cattle manure, control of foam and foaming in treatment processes.

SUPPORTED BY U.S. Dept. of Agriculture

3.0142, INVESTIGATIONS OF BIOLOGY, ECOLOGY AND CONTROL OF INSECT PESTS OF INDIANA LIVESTOCK

R.C. DOBSON, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01585)

OBJECTIVE: Determine the occurrence of livestock insects in Indiana and to assess their importance. Study the ecology, biology and population dynamics of Indiana livestock pests. Initiate, develop and perfect more effective techniques for reducing the ravages and annoyances of livestock pests.

APPROACH: A program of continuous evaluation of changing populations of these pests and the resulting impact on livestock is designed to serve as a bench mark for determining study needs. Attention will be directed toward singling out vulnerable factors for manipulation. The effectiveness of some of the presently recommended control materials and procedures will be studied under Indiana conditions. Changes in procedures and practices will be investigated and incorporated as they prove effective. Attention will be given to new insecticides, new application techniques, the use of sex attractants, quantitative hormone adjustment, environmental disruption, and waste disposal.

PROGRESS: Work continued studying systemic insecticides in water for cattle grub control. Two additional materials were tried with variable results. Ecological studies of insects in natural bovine manure were carried on as well as in insecticidally-treated feces. At the present time it appears that the ecological succession of insects is not only changed but may cease entirely in treated feces. The break- down of chemicals in manure appears to be slower than originally thought, which may lead to serious pollution problems. Determinations of residues picked up by swine in treated corn fields were made and attempts at clearing contaminate swine were started this fall.

SUPPORTED BY U.S. Dept. of Agriculture

3.0143, FARM ANIMAL WASTE DISPOSAL

T.E. HAZEN, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01433)

OBJECTIVE: Characterize physical, chemical and biological properties of livestock and poultry wastes; improve management systems with regard to handling, treatment and disposition of wastes.

APPROACH: Qualitative and quantitative measurements of physical, chemical and biological properties of swine, poultry and cattle wastes from confinement production units will be taken. Methods of manure treatment and disposal presently under consideration are one- and two- cell lagoons, oxidation ditch and sludge digestion. Effect of waste management in a hog confinement unit will be studied to evaluate ventilation and structural design requirements in confinement rearing.

PROGRESS: Experimentation continues on waste handling system for the I.S.U. swine finishing unit. Manure is hydraulically removed from building by a flowing gutter and discharged to an anaerobic lagoon. Lagoon effluent is pumped to an oxidation ditch. Oxidation ditch effluent is pumped to flush tanks in upper end of finishing unit and reused for manure transport. Equipment modifications are underway for year-round operation. BOD of the returned water was between 50 and 100 mg/l, a reduction of over 98%. No coliform were detected. Further monitoring of treatment and animal performance are to be done. Work was completed on the activated sludge treatment of anaerobic swine lagoon effluent. A predictive design equation was developed and

verified. An activated sludge system may be used effectively with an anaerobic lagoon as the complete treatment of liquid swine wastes. A laboratory investigation was conducted to determine suitability of an activated sludge system alone for the treatment of raw swine wastes. Study was discontinued when it was shown that an excessive sludge build-up was taking place, the oxygen demand of the system was excessive and the effluent produced was not of desired quality. System was modified to a mixed anaerobic digester preceeding an aeration vessel. This unit appears to partially overcome the previous disadvantages.

3.0144, DEMONSTRATION OF A RECIRCULATING SWINE WASTE TREATMENT SYSTEM USING A ROTATING BIOLOGICAL CONTRACTOR
J.R. MINER, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010

The overall objective of this project is to demonstrate the feasibility of using treated waste water from a confinement hog production unit for waste removal within the facilities. The specific objectives are as follows: (1) Demonstrate the effectiveness of a flushing gutter system for handling manure from a hog finishing building. (2) Demonstrate the effectiveness of the Rotating Biological Contractor (RBC) system in treating overflow from an anaerobic lagoon receiving liquid hog manure. (3) Demonstrate the suitability of using treated waste water as the flushing medium for hog finishing building. (4) Determine the operating costs and management skills required to operate this waste management system.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0145, FARM ANIMAL WASTE DISPOSAL
J.R. MINER, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01730)

OBJECTIVE: Improve farm animal waste management systems with regard to handling, treatment, utilization, and disposition of the wastes.

APPROACH: Treat the liquid waste to such an extent to allow recirculating the liquid effluent. Anaerobic digestion systems of increased efficiency would appear possible for animal waste treatment. These systems, which involve temperature control and mixing, will be investigated first on a laboratory scale then in operating size units. This would reduce both the water requirement of the system and the water pollution potential of the discharge. The system has definite management, environmental and animal health implications to be evaluated. To be considered successful, this manure handling system should not have adverse effects on animal performance nor should it result in the spread of disease among animals within the unit. Parameters influencing the physical performance of the hydraulic transport system must be measured and similarly the influence of these variable on the physical, chemical, and social environment within the building.

PROGRESS: Study of a recirculating hydraulic manure transport system operated in a building housing 700 finishing swine was continued. The animals deposit manure in two shallow gutters and hourly 125 gallons of treated effluent is flushed down each gutter, transporting the manure to an anaerobic lagoon. Effluent is further treated in a covered oxidation ditch and then returned and used as flushing water. Results this year have been a building which operates with a minimum of odor, without need for pen cleaning, without hauling of manure, and without discharge of pollutants. Decreased performance of the animals which come into contact with the flushing water has not been observed. Work continued in the application of lagoon effluent to cropland. More than thirty inches of effluent containing over two thousand pounds of nitrogen equivalent per acre per year have been applied. Discharge reaching drain tile lines was colorless, free of organic matter and significantly reduced in nutrient concentration. An alternative means of nutrient removal, a hydroponic system utilizing water hyacinths, was initiated. These plants, of semi-tropical origin, grew well under Iowa conditions and showed potential of nutrient removal from partially treated liquid animal wastes.

SUPPORTED BY Iowa State Government - Des Moines

3.0146, OPTIMIZATION TECHNIQUES FOR AGRICULTURAL PROBLEMS
L.T. FAN, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN00737)

OBJECTIVE: Apply systems analysis and systems optimization to agricultural problems. Simulation, optimal design, and optimal control techniques will be developed and demonstrated by application to important agricultural problems. Emphasis will be placed on agricultural problems. Emphasis will be placed on food processes and environmental systems.

APPROACH: Although the approach to be used in this work differs somewhat from problem to problem, it usually involves the following steps: Definition of a performance criterion or objective for the processing system. Development of a mathematical model to describe the processing system. Application of optimization techniques to develop optimal solutions. Analysis of results.

PROGRESS: A mathematical model for the continuously operated bioreactor system which can be used to represent a biological waste water treatment process as well as various types of fermentation processes has been developed. The analysis of steady states if investigated thoroughly. One purpose of this work is to investigate the critical flow rates which will cause washout to occur. The effects of macromixing, micromixing and cell recycle on the critical flow rates which will cause washout are examined. In this work several different mathematical models are presented, such as the single CSTR model which is usually used to model the chemostat, the N CSTRs in series model, the PFR model and the diffusion model. Furthermore mathematical models are obtained which describe batch growth in fermentations with two liquid phases present. Simulation was carried out using CSMP language on an IBM 360 computer.

SUPPORTED BY Kansas State Government - Topeka

3.0147, FARM ANIMAL WASTE DISPOSAL
G.H. LARSON, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN00666)

OBJECTIVE: Characterization of physical, chemical and biological properties of livestock and poultry wastes. Improvement in management systems with regard to handling, treatment and disposition of wastes.

APPROACH: Make a field study of existing waste disposal systems. Representative samples of various animal manures will be collected over a short period of time and will be analyzed. Existing practices for disposal of municipal and industrial wastes will be evaluated in light of information obtained on nature of animal wastes. Based on information obtained, and if possible, a new system will be designed and tested for economic feasibility for disposal of animal wastes.

PROGRESS: Previous work on characterization of runoff from test feedlots for beef cattle with water applied by sprinklers pointed to much slower sedimentation rates than appear to be occurring in field installations. In a period of higher than normal natural rainfall, suspended solids in runoff when feedlot surfaces had been tramped into a slurry ran almost double the highest previously recorded values. With lot surfaces saturated at onset of 3 inches of rain in 8 hours, suspended solids at 2.5 hours were 13,820 and 25,950 mg/l respectively for dirt and concrete lots and at 7 hours the values were 21,750 and 26,520. Population was 200 head per acre. With 400 head per acre corresponding values were: 26,850 and 44,400 at 2.5 hours and 45,200 and 48,600 at 7 hours. Feedlot runoff with 600 micromhos/cm and 50% exchangeable sodium was applied to 3 soils in soil columns. Piezometers showed some decrease in hydraulic conductivity with a sandy soil and a Hastings silty clay loam but results were erratic. Crete silty clay would not let water through the column. Field plots irrigated with feedlot runoff showed no apparent decrease in water intake rate and corn yields were the same for plots irrigated with runoff and others irrigated with well water and fertilized according to standard recommendations. Tests in plant growth chambers showed that very heavy applications of feedlot

manure to land can very seriously retard early growth of corn though germination was not greatly reduced.

SUPPORTED BY U.S. Dept. of Agriculture

3.0148. FARM ANIMAL WASTE DISPOSAL

G.H. LARSON, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN-05-835)

OBJECTIVE: Not Provided

APPROACH: Not Provided

PROGRESS: When population density of cattle in test feedlots was doubled (400 head per acre vs. 200), the pollution potential of simulated stormwater runoff was increased by 25%. Extended wetting of lots until a manure slurry was created on the surface produced contamination in runoff that greatly exceeded values found by the previously developed prediction equation. Work with out-door infiltration plots and with laboratory soil columns to study the effect of feedlot runoff water on hydraulic conductivity of soils encountered difficulty with techniques. Further attempts to get meaningful results are being made. A trailer was built for transporting the fluidized bed incinerator. In field tests, corn plots were irrigated with feedlot runoff from a detention lagoon. Yields equaled those from plots treated with commercial fertilizer and well water. Water intake rate did not seem to be affected. Application for a large grant has been completed, revised and submitted a second time to the FWPCA. The application outlines studies of land disposal of solid wastes and runoff from feedlots.

SUPPORTED BY Kansas State Government - Topeka

3.0149. DEMONSTRATION AND DEVELOPMENT OF FACILITIES FOR THE TREATMENT AND ULTIMATE DISPOSAL OF CATTLE FEEDLOT WASTES

H.L. MANGES, Kansas State University, School of Engineering, *Manhattan, Kansas* 66502

Manure generated in feedlots and stormwater runoff from the feedlots are sources of pollution to streams, groundwater, and land. This research is based on the hypothesis that pollution can be minimized by the orderly disposal of these wastes onto agricultural lands.

The objectives are: (a) to characterize stormwater from the feedlot, (b) to characterize manure generated in the feedlot, (c) to determine the effect of storage in an anaerobic lagoon on quality of feedlot runoff water, (d) to determine the influence of lagoon water loading rates and manure loading rates on the soil, on the soil leachate, on stormwater runoff from the waste disposal area, on removal of nutrient elements from the soil by cropping and on corn yields, (e) to determine the most economical loading of lagoon water and manure onto cropland compatible with pollution control, and (f) to determine the health hazards when feedlot runoff waters are spread onto land through a sprinkler irrigation system.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0150. PRODUCTION EFFICIENCY IN CAGE EQUIPPED LAYING HOUSES AS INFLUENCED BY LABOR PRACTICES

W.M. INSKO, Univ. of Kentucky, Agricultural Experiment Sta., *Lexington, Kentucky* 40506 (KY01017)

OBJECTIVE: Determine standard times for performing different tasks in a caged laying systems, establish economic feasibility of using different types and levels of mechanization, and observe and attempt to solve problems associated with waste disposal, disease prevention, odors and fly control.

APPROACH: A job analysis of work methods indicating time requirements and cost of equipment as a substitute for labor will be made for all operations and sub operations with cages placed in various arrangements including two to six cages per row. Operations timed will indlude feeding, egg collection, cleaning waters and cleaning dropping boards. Project will include work methods and items of equipemnt to cover various levles of mechanization in each of afore metioned operations. With information obtained it will be possible to compute and establish economics of using different types of management and different levels of mechanization in various sized cage laying installations.

PROGRESS: This report covers 47 weeks of management of caged layers with different degrees of mechanization. In 5 of 6 labor categories, manual care of a fourth deck took the most time per dozen eggs or was tied for the most time. The one exception was pit cleaning under stacked cages. Mechanization resulted in lower labor requirements. In cleaning manure pits, manual or semi-mechanical cleaning varied from .20 to .28 man-minutes per dozen eggs, while mechanical cleaning, including clean-up of equipment, took only .08 man- minutes per dozen. Mechanical feeding took .03 man-minutes per dozen eggs, while manual feeding took from .15 to .31 man-minutes. No significant differences were found among groups in either mortality or egg production.

SUPPORTED BY U.S. Dept. of Agriculture

3.0151. TREATMENT AND DISPOSAL OF LOW-LEVEL SLUDGES BY SOLAR EVAPORATION

S.S. KIM, Korean Off. of Atomic Energy, *Seoul, Korea*

Treatment of low-level sludges by solar evaporation is a continuation of the previous research contract No. 566 which was directed to the development of the application of local clays for treatment of low-active liquid effluents. The project involves a study of meteorogical conditions, development of evaporation pan and economical evaluations of the solar evaporation and the whole waste treatment scheme. The first year's programme includes: Selection of the methods of measurement of the evaporation rates and continuous measurement of the evaporation rate during the seasons. Design and construction of experimental evaporation pan and devices for handling of final product. Measurement of evaporation rate of the sludge in the experimental evaporation pan. Determination of evaporating pan capable of handling the yearly sludge production.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

3.0152. LAGOONS FOR DISPOSAL OF BARN YARD WASTES

H.T. BARR, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB01081)

OBJECTIVE: Determine feasibility of disposing of animal waste by lagoon method under La. Climatic conditions: determine if lagoon method can be used for Milking parlor & milk room, Feeding floors for dairy, beef, hogs and chickens, determine what size should be used in order to get satisfactory sedimentation, elimination of odors and to meet the demands of the State Board of Health.

APPROACH: Collect data on efficiency of operation on lagoons now in use. Help install additional lagoons and obtain accurate data for 2-3 year period during operation. Summarize data and calculate correct size and operation for future recommendations on lagoons in Louisiana.

PROGRESS: Further evaluations of a lagoon for poultry were made. The lagoon was used for 1392 laying hens and the production was compared with that of conventionally caged hens. These results are summarized in the following: Feed*** BodyWt., (lbs), No Birds, Egg*, Egg Wt., Mort., Haugh**, Shell, Efficiency, Treatment, Start, End, In Expt., Prod.(%), Oz/Doz., (%), Units, Thick(in.), (lbs.), Lagoon, 2.49, 3.69, 1392, 54.45, 25.30, 20.47, 85.76, 0.0130, 4.42; Control, 2.51, 3.71, 1368, 58.63, 25.50, 11.91, 85.07, 0.0129, 4.62; * 330 Day Production Period ** Measure of Interior Quality, *** Pounds of Feed per Dozen Eggs. Although the difference in feed efficiency results are not statistically significant, it is obvious that the lagoon is performing well. Observations were made on the two swine lagoons and there was a definite accumulation of sludge at a higher rate in the lagoon based on 35 sq. ft. of surface per 100 lbs. of swine as compared with 45 sq. ft. These results are tabulated and reported in a bulletin listed below.

SUPPORTED BY U.S. Dept. of Agriculture

3.0153, DEVELOPMENT OF DIET RATIONS FOR CULTIVATION OF SHRIMP AND CRAWFISH

S.P. MEYERS, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB01507)

OBJECTIVE: Utilization of fish protein concentrate (FPC) and single cell protein (SCP) for aquacultural purposes. Development and testing of various complete rations under controlled aquarial conditions.

APPROACH: Aquaculture is rapidly becoming a large potential source of fish and protein, with considerable economic implications on a world-wide basis. Shrimp cultivation is a major area for exploitation by many food-based and other industries. A big stumbling block is the development of an economical and reproducible food. Similarly, the relatively small, but important, crawfish industry in Louisiana would benefit greatly by development of methodology for artifical cultivation using an efficient low-cost ration to support and accelerate animal growth. The proposed formulation of diets utilizing marine or fish protein, microbial protein (such as yeast cells-SCP) and crude fiber has real practical significance. This is especially evident in currently designed food and fiber waste disposal systems engineered for ultimate microbial conversion of end product into single-cell protein, the latter for use in animal feed supplement, including aquacultural vertebrate and invertebrate crops.

PROGRESS: Cultivation of aquatic and marine invertebrate crops is a significant aspect of a rapidly expanding aquacultural industry. A major stumbling block with invertebrates is development of economical, reproducible, rations for proper growth and nutrition of the animal. Basic diets have been formulated utilizing fish protein concentrate (FPC) and single cell protein (SCP-Torula yeast) as the sole protein supplement, and rice bran at 30-45% as the primary carbohydrate addition. Pellets designed for maximal utilization by the juvenile animals are small (1/8" diameter x 1/2" long) with good 'sinkability' for bottom-feeding specimens. Feeding tests with juvenile shrimp and crawfish show ready utilization of the FPC- and SCP-based rations. Growth rate increments are noted, i.e., doubling in weight in initial two weeks feeding period. Pellet durability index (PDI), using Masonex (hemicellulose) as a binder, requires improvement for maximal utilization efficiency. Pellet 'systems' are under evaluation to effect maximal PDI, controlled nutrient release, and attractability to the animal.

SUPPORTED BY Louisiana State Government

3.0154, BEDDING AND INFILTRATION STUDIES OF SANITARY SEWERS IN THE GULF COAST AREA

F.W. MACDONALD, Tulane University of Louisiana, School of Engineering, *New Orleans, Louisiana* 70118

The purpose of this project is to determine the best types of bedding arrangements and the most suitable materials to be used in laying sewer pipes in the Gulf Coast areas, including studies on manholes, and other appurtenances of sewer systems. A major portion of the project will be infiltration studies using various materials of construction. Some of the studies will be with a testing frame in the University laboratory, while other studies will include field studies of sewer lines in the area.

3.0155, NEW FOOD PRODUCTS AND SERVICE

M.E. HIGHLANDS, Univ. of Maine, Agricultural Experiment Sta., *Orono, Maine* 04473 (ME03059)

OBJECTIVE: Processing problems, new developments and services to the food industry on processing.

APPROACH: Among items that have been encountered are: lye peeling of squach, evaluation of new apple varieties for canning, evaluation of new dry bean varieties for canned baked beans, evaluation of Maine canned tuna. Service problems on various analytical methods and development of simplified techniques for quality control have been worked out. Work in the area of processing plant waste disposal has also been done. Work along the above lines will be continued.

PROGRESS: Work on the relation of holding time at 30-32 F to sensory panel preference for texture and flavor of Maine shrimp was investigated. Results indicate a tendency for increased preference for shrimp held four to five days at 30-32 F with regard to flavor and texture as opposed to shrimp held one to three days under the same conditions. Sanitary surveys of three shrimp processing operations including one canning plant, one prepeeled freezing operation, and one precooked, non-peeled chilled operation were examined. Evidence of improved sanitation requirements were observed in the canning operation and suggestions for correction were made. Examination of cultures from shrimp processing operations are continuing with the view of establishing sanitary improvement and possible significance of these organisms in consumer utilized shrimp products. Service research and development work was carried out on processing of battered breaded fried, frozen poultry products, resulting in improvement of these products and selection of proper battering materials. Microbiological examinations of processed and non-processed poultry products were made in connection with establishing the sanitary integrity of the finished processed product. Recommendations with regard to sanitation and handling of the processed products were made and when applied resulted in products of acceptable sanitary condition and quality.

SUPPORTED BY Maine State Government

3.0156, DISPOSAL AND UTILIZATION OF DAIRY AND POULTRY MANURES BY LAND APPLICATION

A.F. KLINGE, Univ. of Maine, Agricultural Experiment Sta., *Orono, Maine* 04473 (ME00222)

OBJECTIVE: Develop and evaluate disposal and utilization systems for land application of treated and untreated dairy and poultry manure that will minimize the pollution of water, soil, and air.

APPROACH: Relationships among temperature, moisture, air flow and drying rates of fresh poultry manure under various environmental conditions will be determined. Drying will take place in an insulated bin. Mathematical relationships among temperature, relative humidity, air flow rate and moisture content will be determined for the drying process. Pollution effects of the dehydrated poultry manure when applied to soil will be evaluating using rainfall simulators producing up to 5.0 inches per hour. Surface runoff will be measured and percolate analyses will include COD, NO(3), Na, NH(4), PO(4), NO(2), at three depths in the soil.

PROGRESS: Poultry manure from pits was dried by blowing heated air over the surface of the manure as it was being stirred in an insulated chamber. Average initial conditions of the manure were: moisture content, 65%; total nitrogen 1.15%; nitrogen from ammonia, 0.54%; and potassium, 1.40%. Average conditions after drying were: moisture content, 12%; total nitrogen, 6.18%; nitrogen from NH(4), 0.51%; and potassium 2.43%. Volume reduction during drying out was about 50%. The dried manure was applied to 10' x 20' plots on Caribou loam at rates of 0, 7, and 28 tons per acre and disced in lightly just prior to the application of 1.25 inches of water in approximately 50 minutes by rainfall simulator. Surface runoff from the plots was collected and analyzed with the following average results: control plots, 7.54 ft of runoff containing 1.19 ppm NO(3) and 0.21 ppm NH(4); 7 tons per acre plots, 8.96 ft. of runoff containing 2.76 ppm NO(3) and 8.72 ppm NH(4); 28 tons per acre plots, 4.94 ft. of runoff containing 4.01 ppm NO(3) and 23.56 ppm NH(4). One month later, water was again applied in a like manner with the following average results: control plots, 14.32 ft. of runoff containing 3.82 ppm NO(3) and no NH(4); 7 tons per acre plots, 13.36 ft. of runoff containing 7.88 ppm NO(3) and 2.38 ppm NH(4); 28 tons per acre plots, 5.35 ft. of runoff containing 7.89 ppm NO(3) and 11.37 ppm NH(4).

SUPPORTED BY U.S. Dept. of Agriculture

3.0157, DESIGNING AND TESTING HYDRAULIC HANDLING SYSTEMS FOR POTATOES, SUGAR BEETS AND OTHER CROPS

N. SMITH, Univ. of Maine, Agricultural Experiment Sta., *Orono, Maine* 04473 (TF1-094A)

3. SOLID WASTE MANAGEMENT

OBJECTIVE: Design and test hydraulic (fluming) systems for handling potatoes, sugar beets, and other crops which will reduce operating costs without impairing market quality of product being handled

APPROACH: Engineering studies to evaluate principles of various systems for hydraulic handling of crops, including open and closed, above and below floor level, fixed and portable systems; lateral and main flume layouts and configurations evaluated; auxiliary items including pumps, sumps, and sump clean out and disposal systems will be developed. Product damage and deterioration studied. Prepare complete set design criteria and operating procedure. Engineering-economic cost comparison with other typical handling systems.

PROGRESS: Further tests were conducted with the closed pipeline system after adjusting initial instrumentation. Stored Katahdin potatoes were run through the system to obtain water headloss figures and to evaluate potato damage. Small potatoes showed negligible damage and only very slight skinning at all conveying velocities (up to 10 ft. per sec.) while large potatoes showed minor cuts and light skinning at conveying velocities above 7 f.p.s. No severe damage found. Potatoes passed through the system 50 times per hr. for 6 hours still retained over 50 percent of their skin, indicating potential for economical, high-speed movements in smooth pipes. Damage tests were also continued with Russet and Kennebec potatoes. Flume intersection angles of 90 , 60 , and 45 were designed and fabricated as well as the remainder of the other equipment needed for trials in 10-inch trapezoidal flumes. Fluming tests were run to evaluate the effects of flume intersection angles on flow profiles and bruise damage using three rates of potato supply and two rates of water supply. Design calculations were made for circular flume sections. Data obtained from previous trials with rectangular flumes were processed. Mechanical and hydraulic methods for sump cleanout were analyzed. Data from tests conducted over a three- year period were summarized and partially analyzed.

3.0158, LITTERLESS HIGH-DENSITY BROILER PRODUCTION SYSTEM

R.B. WILLIAMS, Univ. of Maine, Agricultural Experiment Sta., *Orono, Maine* 04473 (ME00212)

OBJECTIVE: Evaluate various non-litter materials in respect to their use as broiler flooring. Determine methods of removing waste materials from this flooring on a continuous complete disposal basis; determine extent of carcass defects occurring during growing, handling and transporting operations while utilizing the flooring; use this information for development of a litterless, high density, controlled growing and handling system for broilers.

APPROACH: Broilers will be raised on a number of non-litter flooring materials to find a satisfactory alternative to litter. Carcass quality and production efficiencies will be determined. A method of removal and disposal of waste will be developed and a growing- handling container for use in the litterless fully mechanized production system will be developed.

PROGRESS: The broiler growing and handling cage unit has been redesigned to include direct transport of the growing cage to the processing plant. These units are now under construction and will include several new selfcleaning flooring designs. Uniform grading of test birds for carcass quality was a problem in the past due to high speed of the processing line. A system of handling has now been established with one of the local commercial processors to allow greater detail in carcass grading.

SUPPORTED BY U.S. Dept. of Agriculture

3.0159, SLUDGE DISPOSAL AND MATERIAL RECOVERY SYSTEM FOR MANUFACTURERS OF COATED AND/OR FILLED PAPERS

R.P. LABRECQUE, Scott Paper Company, *Westbrook, Maine* 04092

A proposal has been made to incinerate dewatered primary treatment sludge by using a rotary kiln incineration process. Since the sludge in question contains a very high amount of paper making pigment and consequently is not amenable to conventional sludge incineration processes, an incineration process has been developed which will allow economical recovery of the pigment so that it can be reused as a replacement for virgin filler pigment during the paper making operations.

Extensive laboratory and field trials have shown that, through careful control of incineration temperature and retention time in the incineration system, a pigment product which is equal to or superior to most paper making pigments can be recovered from the waste sludge as the ash resulting from the incineration process.

The project has been divided into two phases. The project in question, Phase I, will consist of a large scale mill trial during which ten tons of sludge will be processed. Phase III, which may follow Phase I, will consist of the construction and trial operation and evaluation of a full size recovery system composed of a 250 ft. rotary kiln, four pigment pulverizers and a pigment storage-distribution system.

Phase I of the project will begin in May, 1970 and will end in April, 1971.

3.0160, ACCELERATED BIODEGRADATION OF SANITARY WASTE SOLIDS

W. VANHEES, U.S. Navy, Ship Research & Dev. Lab., *Annapolis, Maryland* 21402

Technical Objective: Development of information necessary for rapid microbial solubilization and digestion of cellulose and similar solids in sanitary waste, applicable to prospective use in designing shipboard waste treatment systems.

SUPPORTED BY U.S. Dept. of Defense - Navy

3.0161, CHEMICAL AND PHYSICAL TREATMENTS OF CATTLE EXCRETA FOR REDUCING ENVIRONMENTAL POLLUTION

L.W. SMITH, U.S. Dept. of Agriculture, Animal Science Research Div., *Beltsville, Maryland* 20705 (033107090121)

OBJECTIVE: Reduce the pollution potential of cow feces by chemical and physical treatment and evaluate the feed value of treated fecal fractions.

APPROACH: Feces of dairy cattle and sheep will be fractionated into water soluble and non-water soluble portions. Whole feces and water soluble portions will be treated with heat, cold and chemicals to reduce solubility of constituents. Isolated insoluble fractions will be treated with delignifying agents to increase the availability of cellulose. These treated materials will be added to rations of experimental animals.

PROGRESS: Laboratory chemical treatments of total fecal dry matter or isolated fecal cell walls has been completed. Sodium hydroxide was found to be the most economical chemical for solubilizing cell walls and for enhancing in vitro digestion of fecal fiber. Additional intake and digestion trials have been conducted using sheep fed rations containing 85% ground or pelleted dehydrated manure which was nearly free of bedding. Digestibilities of DM were 43, 52, 55 and 53% for untreated, NaC10(2), Ca(C10)(2) and NaOH treated ground dairy cattle manure. Digestibilities were lower when the rations were fed pelleted (37, 46, 47 and 57, respectively) except for the NaOH treated which increased. These digestibilities are higher than those observed on saw-dust containing manure. Consumption of the untreated manure pellets was highest (3.5% of body weight per day). A growth trial is in progress with 15 dairy heifers on rations composed of Manure:corn meal at ratios of 1:1, 2:1 or 3:1. Consumptions exceeding 2.0% BW are being observed.

3.0163, REFINING OF MOLTEN FERROUS SCRAP

H.V. MAKAR, U.S. Dept. of the Interior, Bureau of Mines, *College Park, Maryland* 20740

Project objective is to develop an economical method of copper removal from molten ferrous scrap.

Research in progress includes: A. Rate studies on slag metal reactions between molten iron and alkali slags; effect of carbon content of the iron on copper removal; removal of other impurities; and feasibility of spent slag recycling. B. Development of special processing techniques, such as lance injection and counter-flow operations, to improve efficiency of slag-metal reactions.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0164, ANIMAL WASTE COMPOSTING EQUIPMENT FOR THE NORTHEAST

J.W. HUMMEL, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (901-031-B610)

OBJECTIVE: Develop methods for disposal of livestock and poultry production and processing wastes.

APPROACH: Create new concepts of design criteria and prototype machines for composting animal wastes by studies of: use of hydroponic techniques to remove plant food elements; longitudinal flow; air entrainment requirements and techniques; transport and mixing; confining platforms and channel shapes and sizes; precompost treatment requirements; the use of chemical and biological additives to facilitate and/or accelerate the composting process; capacities in relation to production unit size; and impact on livestock and poultry production systems.

PROGRESS: Plans were developed for the channel to be used for the composting mechanization system. Material was obtained and a test section constructed. Length of the test section was approximately one- third of the anticipated prototype model. Cross-sectional area was full-scale. Plans were drawn up and a first-generation model of the elevating and mixing mechanism was constructed. The unit was designed to elevate at different pitches and rates of flight movement. Torque measurements were made to evaluate power requirements for the unit. Preliminary tests indicated some modifications were required. Modifications were made and additional tests conducted. A means of propelling the unit forward was designed. Combinations of wet sawdust and other additives to simulate animal waste were tried. Dye material to color the sawdust was investigated. The dyed sawdust will be used to determine mixing capabilities of the elevating an mixing mechanism.

SUPPORTED BY U.S. Dept. of Agriculture

3.0165, USING WASTE FORMED IN VEGETABLE AND CHEESE PRODUCTION

A. KRAMER, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (MD-Q-085-A)

OBJECTIVE: Study the chemical, nutritional, microbiological composition of waste materials occurring during the manufacture of processed tomatoes, cottage cheese, and other fruits, vegetables and cheeses; investigate the possibility of utilizing these waste products as food or feed, for men, animals, plants or soils; and manipulate such wastes by means of drying and ensiling, and where possible, use of chemicals, additives and solvents to yield additional uses for the raw materials.

APPROACH: First work will be directed to determining the chemical, nutritional and microbiological composition of tomato and cottage cheese waste materials. Work on other product wastes will follow. Feeding and plant growth studies will be used to determine possibilities for feeding ruminants or in crop production.

PROGRESS: A process of utilizing tomato cannery waste was developed where press-cake containing 2/3 of total solids, 10% protein is usable as cattle feed, and 1/3 of solids, 60% protein is precipitated as a Tomato Protein Concentrate. This concentrate can be extracted with acetone to form an 85% protein isolate, and a tomato flavor and pigment residue may be obtained during the acetone recovery. Significant phytotoxic effects are limited to ripe tomato fruit components. When properly processed by HTST pasteurization, cheese whey can be used up to 50% in place of milk for the manufacture of sherbet and ice cream, and mixed with tomato or fruit juices as a 'breakfast' drink.

SUPPORTED BY Maryland State Government

3.0166, DISPOSAL OF WASTES FROM SWINE FEEDING FLOORS TO MINIMIZE STREAM POLLUTION

W.F. SCHWIESOW, Univ. of Maryland, Agricultural Experiment Sta., *College Park, Maryland* (MD-R-029)

OBJECTIVE: Investigate methods for disposing of waste from swine feeding facilities. Develop guide lines for design of systems to minimize water pollution by swine wastes.

APPROACH: Use of a sedimentation tank, sprinkler system, tile distribution field, and field spreading in several combinations are to be investigated. Waste products coming from the swine production unit will be analyzed to determine the liquid-solids ratio, available nutrients--N, P, K, BOD and COD. The waste will be run through a sedimentation. Liquid waste, measured by a flow meter at the tank outlet, will be pumped to an adjacent field and distributed by sprinkler or under ground tile system. Solid wastes will be drawn from the sedimentation tank by a vacuum type spreader and placed on a field. Immediate and delayed coverage will be practiced.

PROGRESS: The basic installation has been completed. A lysimeter 200' long, 2' wide and 4' to 7' deep was constructed. Twenty-six test plots were built. Each plot having a 10' x 10' test area. Solid wastes were applied at rates of 25, 50, 75 and 100 tons per acre to 12 plots on one side of the lysimeter. Grass did not become established this year. Effluent was applied to 12 plots on the other side of the lysimeter. Application rates were 1, 2, 3 and 4 inches per week for nine weeks this year. Two untreated check plots are maintained--one on each side of the lysimeter. Soil samples were taken before treatment began. Samples were taken of the effluent before application and of water percolating through the soil. Percolating water was collected by slotted plastic chains installed at 6', 12', 24' and 72' levels were permitted by lysimeter depth. Sampling of the percolate water continues. These samples are now being analyzed for nitrogen, phosphorous, calcium, sodium and chlorides. Effluent application is to be resumed next year.

3.0167, FARM ANIMAL WASTES MANAGEMENT

G.B. WILLSON, Univ. of Maryland, U.S.D.A. Agric. Engin. Div., *College Park, Maryland* 20742 (901-031-B603)

OBJECTIVE: Develop methods and facilities for handling, reclaiming and/or disposing of farm animal wastes economically and without environmental pollution hazard or aesthetic nuisance.

APPROACH: Conduct studies to design, test and evaluate methods and facilities for handling, holding, transporting, disposal and/or utilization of farm animal wastes. Studies will be included to develop technology for the use of composting as a method for reducing the volume of wastes and transforming them into an innocuous material for disposal or utilization. These studies will include an evaluation of physical, chemical and biological characteristics that will influence the design and operational methods used in the composting process. Studies will be made of the use of filters and other methods of removing odors and dusts from the exhaust air from poultry houses.

PROGRESS: A new laboratory facility for farm animal waste management research was constructed by the University of Maryland. This facility is the site for cooperative research on the composting process for treating farm animal wastes. Although the facility was not completely ready for use until December, some exploratory work was initiated in the fall. Studies of the compost

process have shown that dairy cow manure and bedding in approximately halfston batches can be digested to a relatively odorless material. The process reduces total dry matter 60% and could with drying reduce the weight by 85%. The volume is reduced about 30% in the loose state and could be reduced further by compaction or pelleting. Temperatures achieved (150 -170 F.) were adequate to kill pathogenic organisms and weed seeds are digested in the process. Aeration has reduced process time about 50%. Studies of the use of filters to clean poultry house exhaust air have shown that baffle impingement filters reduce the dust emission 1/2 to 2/3. A fog nozzle between the exhaust fan and the filter increases the efficiency, particularly for the smaller size particles. A marked reduction in odor strength was observed under both operating conditions, with wet operation being more effective.

SUPPORTED BY U.S. Dept. of Agriculture

3.0168, CLOSED SYSTEMS FOR ANIMAL SEWAGE TREATMENT

J.T. CLAYTON, Univ. of Massachusetts, School of Agriculture, *Amherst, Massachusetts* 01002

The specific objectives of the proposed research are: (1) To develop a waste stabilization system that will minimize the polluting strength of manure and other dairy farm wastes; and (2) to clarify, by digestion and subsequent treatment, the liquid (or liquifiable) parts of dairy farm wastes so that the system effluent can be safely disposed of or used as the agent for subsequent cleanings of the dairy facility.

Two experimental sewage processing systems will be used. The first will consist of primary settlement of the influent with secondary aerobic digestion. In the second system aerobic digestion will precede settlement. Effluent quality and the fate of indicator organisms, will be the principal criteria of performance.

Microbiological determinations will be made in order to obtain the following information: (a) the activities in the various stages of the process; (b) the public health hazards associated with the final sludge and effluent; and (c) to determine the degree of disinfection necessary before discharge.

Later experiments will include the use of coagulants, coagulant aids, and chemical treatments. Dosage and effectiveness of ion exchange minerals and resins will be investigated with special emphasis on odor and color effects. Chemical treatments for microorganism control and small organic particle removal will be studied.

3.0169, THE CONSTRUCTION OF THE STORM DETENTION AND CHLORINATION STATION

H. WHITMORE, Metrop. District Commission, *Boston, Massachusetts* 02108

The storm detention and chlorination station is being constructed for the treatment of storm water overflows from the combined sewage system of the cities and towns bordering on the Charles River Basin. The proposed installation will be capable of handling a maximum of 230 million gallons per day of excess flow from the new and old sewerage systems. Consisting of screening and pumping facilities, chlorine dosing and detention facilities and skimming and flushing facilities, this installation will be fully automatic and will become an integral component of the overall sewage control program for Metropolitan Boston. A comprehensive sanitary survey of the Basin is now underway and will be followed up by correlation of operation data with rainfall; frequency and extent of overflows; physical, chemical and bacteriological analyses of influent and effluent; regrowth of coliforms; effectiveness of chlorination and solids removal with measurements of solids returnto sewer; effectiveness of the double-sided overflow weirs in relief conduits; effectiveness of effluent diffusers into Basin and overall unit cost studies relating to operation, utilization and performance of the installation. Scheduled to be under construction in the Fall of 1967, the facility will be in preliminary operation in the Fall of 1969.

3.0170, EFFECTS OF HEAVY METALS ON ALGAL GROWTH AND ORGANIC REMOVAL EFFICIENCY IN STABILIZATION PONDS

W.R. DOMEY, Northeastern University, School of Engineering, *Boston, Massachusetts* 02115

Many heavy metals are present in industrial wastes which may be discharged into stabilization ponds for muncipal waste treatment. This study will determine the effects these metals have on oxygenation capacity and on growth of algae. The effect that these metals have on the efficiency of the waste treatment facility will also be determined.

SUPPORTED BY Northeastern University

3.0171, KINETICS OF SEWAGE DEGRADATION IN SEA WATER

W.R. DOMEY, Northeastern University, School of Engineering, *Boston, Massachusetts* 02115

Ocean disposal of sewage wastewaters usually is predicated on the dispersal capacity of the sea. This study will generate data for the degradation of the waste as opposed to the dispersal phenomena, which must have some eventual limitations.

SUPPORTED BY Northeastern University

3.0172, MICROBIAL CONTAMINATION OF AIR NEAR OPEN WASTE TREATMENT FACILITIES

C.J. GREGORY, Northeastern University, School of Engineering, *Boston, Massachusetts* 02115

Bacteria are emitted from agitated waste treatment facilities such as aeration tanks and, depending on environmental factors (wind, temperature and humidity), may constitute a health hazard to treatment plant operators and nearby residents. The significance of such emissions is under study at an existing activated sludge waste treatment facility.

SUPPORTED BY Northeastern University

3.0173, ENVIRONMENTAL SYSTEMS PROGRAM

H.A. THOMAS, Harvard University, School of Engineering, *Cambridge, Massachusetts* 02138

Drawing on the disciplines of engineering, applied mathematics, economics, political science, and city and regional planning the Environmental Systems Program will conduct research on the technical, economic, social, and political aspects of problems of environmental quality. Major aims are to train graduate students and post-doctoral fellows in the successful conduct of interdisciplinary research.

The research program involves the cooperation of the School of Public Health, the Graduate School of Design, and the John F. Kennedy School of Government and includes analysis of environmental management institutions; economic analysis of individual decision units; studies of municipal financing of environmental control systems; expansion of current studies of solid waste disposal; and studies of the epidemiology of urban fires. The research program will involve graduate students and post-doctoral fellows in order to develop the talent required for intelligent management of environmental quality management.

3.0175, INVESTIGATION OF NEW WASTE DISPOSAL/SANITATION TECHNIQUES FOR GARRISON FOOD SERVICE
D.B. CORNFIELD, U.S. Army, Natick Laboratories, *Natick, Massachusetts*

Technical Objective: To determine the feasibility of an automated scullery operation and to investigate techniques of waste disposal.

SUPPORTED BY U.S. Dept. of Defense - Army

3.0176, URBAN WASTE DISPOSAL IN THE SLUM DISTRICTS OF SOUTH BOSTON AND ROXBURY
W.R. JOHNSON, New England Comm. Dev. Corp., *Roxbury, Massachusetts* 02119

The grant in Boston will carry forward research begun in 1969 on urban waste disposal in the slum districts of South Boston and Roxbury. A group including Harvard faculty, the Triton Foundation, and the Organization for Social and Technical Innovation will design demonstration projects and work with the Boston Model Cities Project and other organizations to determine the best ways to dispose of solid wastes in city neighborhoods. Work to date has found, for example, that the system of waste management in Boston is too rigid. Any deviation results in a littered neighborhood--e.g., if waste is put in bags instead of cans, or if cans are too far from the curb, it is not picked up.

SUPPORTED BY Ford Foundation - New York, N.Y.

3.0177, THE ELECTRO-OXIDATION OF AMMONIA IN SEWAGE TO NITROGEN
D.L. BROWN, Ionics Incorporated, *Watertown, Massachusetts* 02172 (14-12-432)

Semiconducting electrodes will be studied with the object of finding an electrode for the electro-oxidation of ammonia to nitrogen in wastewater. A large number of materials will be screened under a variety of operating conditions. Tests will be run on a simulated sewage effluent containing ammonia levels in the range of 10 to 30 ppm. Candidate electrode materials will be evaluated by a three step procedure: (1) conduct potential sweep tests; (2) prepare stepped potential curves for materials that look promising; and (3) for the most promising materials, place them in an electro-chemical cell and run a sufficient time to obtain reliable analytical data.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

3.0178, FLOWING BIOLOGICAL SYSTEM IN AQUACULTURE, SEWAGE TREATMENT AND POLLUTION ASSAY
J.H. RYTHER, Woods Hole Oceanographic Inst., *Woods Hole, Massachusetts* 02543

The primary objective of this research is to design procedures and techniques by which various uses of waste effluent may be made compatible. It combines sewage treatment with aquaculture, thus concentrating two essential uses of the coastal zone in one confined area (food production and waste disposal), leaving contiguous waters free and unaffected by these uses for recreational or esthetic purposes.

SUPPORTED BY U.S. National Science Foundation

3.0179, ENGINEERING PROPERTIES OF COMPACTED ASH FILLS
D.H. GRAY, Univ. of Michigan, School of Engineering, *Ann Arbor, Michigan* 48106

The annual projection of fly ash or ash produced from the incineration of sewage wastes poses a serious disposal problem. An effective solution would be to compact this material and use it as a structural fill or construction material. This might include such potential applications as lightweight backfills, highway embankments, and road subbases.

In order to use these ashes successfully for such purposes their chemical, physical, and engineering properties must be determined. It is also important to investigate possible health or environmental hazards posed by such usage.

The research is presently aimed at determining the compaction characteristics of various ashes, strength and compressibility of the ash after compaction, frost susceptibility, age hardening properties, and response to various stabilization treatments. In addition, such chemical properties as COD, aggressiveness of the ash towards metals and vegetation are also being measured.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0180, ELECTRICAL STIMULATION OF MICROBIAL WASTE TREATMENT
J.S. SCHULTZ, Univ. of Michigan, School of Engineering, *Ann Arbor, Michigan* 48106

Project objectives are to establish operating conditions for stimulating microbial growth and metabolism by electrical techniques and to ascertain design methods for the use of electrically stimulated cultures in bioregenerative waste handling systems.

The program is planned to delineate the effects on microorganisms of various types of electrical stimuli, such as AC, DC, and pulsed; to determine the efficacy of electrical stimuli for increasing the rate of microbial growth and waste handling capability; and to investigate the mechanism of the stimulatory effects.

Electrical effects will be tested in both batch and continuous culture of microorganisms. Electrical effects will be evaluated in terms of microbial growth, rate of substrate utilization, and permeability of the cells to specific metabolites.

This project was initiated on June 1, 1967 and will terminate on April 30, 1970.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0181, FARM ANIMAL WASTE DISPOSAL
J.S. BOYD, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL01021)

OBJECTIVE: Characterization of physical, chemical, and biological properties of livestock, animal and poultry waste, and improvement in management systems with regard to handling, treatment and disposition of waste.

APPROACH: Animal wastes will be dried to provide a material which can be stored and spread under optimum field conditions. Two high temperature dryers are available. The work on electro-osmosis as a means of reducing moisture will be continued. Several lagoons will be studied from the standpoint of management and operation, of which two are on the MSU campus. Aeration may be incorporated in the lagoon to improve the efficiency of operation. Plans will be developed for use of an aerobic digester for animal solid wastes.

PROGRESS: Results of tests were presented to groups to get their reaction to the practice of drying animal manure. One of the problems was capacity of the dryer. This would be used on large farms of 100 dairy cows, 600 steers, or 20,000 hens. One company in Michigan now has made a prototype of dryer which has two times the capacity which would be good enough for 50 dairy cows. A system of collecting manure in free stall dairy barns is also being investigated. This has been used successfully in Sweden and Finland. DeLaval is interested in selling it in the U.S.A. Initial contacts have been made to install the first one on a Michigan farm in Shiawassee County. Mr. Gail is presently constructing a new 60-cow barn and has used a size which will fit this type of manure collector. During the coming year this building should be completed and hopefully a unit operating. Then cost studies and time studies will be made.

SUPPORTED BY U.S. Dept. of Agriculture

3.0182, CLOSED SYSTEM WASTE MANAGEMENT FOR LIVESTOCK
M.L. ESMAY, Michigan State University, School of Agriculture, *East Lansing, Michigan* 48823

3. SOLID WASTE MANAGEMENT

It is the broad objective of this research to determine the design parameters of a self-contained, automated animal waste management scheme.

The specific objective is the development of a liquid manure processing system which is capable of fractionating animal waste into its liquid and solid components, neither of which would cause aesthetic or pollutional problems after processing.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0183, SWINE HOUSING ENVIRONMENT

M.L. ESMAY, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00981)

OBJECTIVE: Develop and verify design criteria for control of the thermal environment for swine production.

APPROACH: Develop adequate information for prediction of air flow patterns, jet stream velocities, air entrainment, thermal mixing, air stratification, moisture diffusion and air management in general for design of precise ventilation systems. Air flow patterns will be studied in a 1/4 scale model and full scale buildings. Air flow rates and slot inlet design and location will be varied. Both theoretical and empirical approaches to the problem will be made.

PROGRESS: Functional planning and structural designs were completed for a swine farrowing house and a nursery-finishing house. Plans were developed for these two buildings for distribution through the M.S.U. Agricultural Engineering Extension Plan Service. Both houses included the design details for slatted floors and liquid handling of animal wastes. Plans for an Animal Waste Laboratory and an experiment swine finishing building were developed and construction was started. Two research studies pertaining to ventilation air flow and temperature patterns in livestock and poultry buildings were made.

SUPPORTED BY U.S. Dept. of Agriculture

3.0184, FARM ANIMAL WASTE DISPOSAL

C.J. FLEGAL, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00928)

OBJECTIVE: Characterization of physical, chemical, and biological properties of livestock and poultry wastes; improvement in management systems with regard to handling, treatment and disposition of the wastes.

APPROACH: Electro-osmosis principle of drying animal and poultry manure will be investigated. Amount of electrical current and design of a material used in electrodes will be studied. Time required to dry material and amount of moisture remaining in material when system stops operating will be determined. Water removed and residue will be analyzed. Bulk density of manures and orientation of electrodes will be investigated. Use of air, mechanical agitation, and pumping (circulating) will be accomplished investigated as a means of increasing aerobic digestion. This will be accomplished in small tanks with controlled amounts of manure added daily. In addition one or more full scale tanks in pens with a high density population will be used.

PROGRESS: A pilot study was conducted to determine the feasibility of nutrient recycling of dehydrated poultry waste utilizing laying hens. Egg production was lowered when 40% dehydrated poultry waste was incorporated in the diet. All levels tested (10, 20 and 40%) resulted in reduced shell thickness. No carryover of taste was determined in scrambled or hard-cooked eggs. Hen day production in those birds receiving 10 or 20 percent dehydrated poultry feces was similar to the production of the birds on the control diet. Feed efficiency was similar for the birds on the control diet when compared to the birds receiving the 10 percent level of dehydrated poultry waste, however, the other levels tested resulted in poorer feed efficiency when compared to the birds receiving the control diet.

SUPPORTED BY U.S. Dept. of Agriculture

3.0185, SYSTEMS APPLICATIONS IN AGRICULTURE

J.B. HOLTMAN, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL01028)

OBJECTIVE: Development and execution of programs for the solution of particular agricultural problems will be investigated which include: dynamical farmstead modeling; control and design of woods harvesting operations; determination of optimum systems for assembling, storing, and distributing cash grains in the Great Lakes region; systems aspects of animal waste management and utilization.

APPROACH: Several different types of farming systems will be considered. Existing data will be compiled and additional requirements determined and collected. The data will be analyzed statistically and models will be formulated on the basis of statistical tests and feasibility of subsequent analysis. Simulations will be designed for woods harvesting systems. The compatability with respect to work scheduling and of various equipment will be studied. The flow of cash grain from producer to terminal operations will be studied which involves mathematical modeling of cash grain flow and the subsequent analysis of the results for improvement of current operations. The movement and utilization of animal wae will be analyzed from a systems approach. A working model will be simulated and studied for possible improvements and performance.

PROGRESS: Much developmental work has been accomplished on the problem of dynamical farmstead modeling. A long range model structure has been established. Many of the hydrolical and biological component models are complete at this time.

SUPPORTED BY U.S. Dept. of Agriculture

3.0186, ELECTRO-OSMOSIS

C.J. MACKSON, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00788)

OBJECTIVE: Determine effect of electro-osmosis on living plants, determine the effect of electro-osmosis of the removal of water from chicken excrement.

APPROACH: Subject small trees to electro-osmotic process to determine potential difference needed to force water through the tree and to determine the effect of the additional water. It is also planned to use the process on cut flowers and other plants after the technique has been determined. Use various DC voltages to determine the possibility of removing moisture from wet poultry manure.

PROGRESS: The concept of electro-osmotic flow in plants was examined. After a review of fundamental bases of plant anatomy and physiology a model of xylem vessels was developed. The energy flow through this model was analyzed mathematically. The energy balance equation was solved for dissipated energy, considered the source of generated electric energy. This relationship was examied by forcing water through a pad of cellulose filter papers. Water head varied and voltage, current and flow rate were measured. The results showed the source of electric energy may not be an 'intrinsic constant quantity' of the material and the liquid, as is assumed in the zeta potential concept, and rather may be a product of the flow process itself. A theory - 'The Electron Accumulation Theory' was developed to reflect this finding. Physiological processes of plants which may be explained by this theory include the negative charge on root hairs and, when combined with the high observed, tensile stress of xylem sap, may cause this sap to act as a communication system along tHe whole height of the plant. Application of the results to the plant irdicate that electro osomsis as defined does not play a role in sap movement in xylem vessels.

SUPPORTED BY Michigan State Government

3.0187, LABOR EFFICIENCY AS AFFECTED BY DAIRY HOUSING FACILITIES

J.A. SPEICHER, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00796)

OBJECTIVE: A study is to be made of 16 dairy housing units. Eight are conventional free-stall housing, and eight are covered free-stall housing systems. Four of each system use liquid manure storage and handling.

APPROACH: The detailed study will be made of the general arrangement of the building and the farmstead, labor requirements for the major dairy chores associated with the dairy operation, efficiency in the case of labor force, methods of handling

forage and manure, investment and other phases of these dairy systems.

PROGRESS: Differences in labor efficiency between open-lot and covered free stall dairy housing was compared. Eight dairy farms of each of the two types of free stall housing were selected for comparison. Units selected were relatively new and of comparable size. Liquid manure was included in 5 of the covered units and 3 open lot units. One complete day per month was spent on each farm measuring the time required to perform the various chores, in addition the operators maintained records on specified tasks. Seventy percent of the total chore time spent on the cow herd was devoted to milking and cleaning equipment. The most efficient milking parlors were herringbone parlors with 4 units per man. Chore time was affected by type of housing, kind of roughage, and method of handling manure. Covered units gained markedly in efficiency when dry hay was eliminated from the ration. Liquid manure increased labor efficiency in covered systems but not in open lot systems. The study showed dairy housing systems of covered free stalls, liquid manure handling and silage feeding to be more efficient than any other system studied.

SUPPORTED BY Michigan State Government

3.0188, THERMOPHILIC METABOLISM IN SOLID SUBSTRATES

M.E. STEPHENSON, Michigan State University, School of Engineering, *East Lansing, Michigan* 48823

With the continued increase in the generation of urban solid wastes, it is imperative that detailed methodology and basic information regarding disposal technology be developed. The sanitary landfill is one of the two generally accepted methods of refuse disposal. To date, research on this system has been conducted almost exclusively through field studies with little definitive laboratory investigation involved. Published field investigations have not provided quantitative information regarding the full extent and composition of the products of decomposing refuse or the generalized kinetics of conversion to a stable condition. Recent field studies indicate that a rapid rate of approach to stability may be obtainnd under aerobic, thermophilic conditions.

Thus, it is the objective of this study to develop a valid laboratory model of the reacting system and to measure both the macro- and micro-components of the products of the decomposition process. As an ancillary objective, this study has resulted in the modification and development of analytical techniques necessary for the determination of the physical and chemical constituents related to the decomposing mass. Practical parameters of stability have been proposed on the basis of this investigation.

3.0189, STORAGE AND DISPOSAL OF WASTES RESULTING FROM THE CONCENTRATION OF LOW GRADE IRON ORE

C.R. BAILLOD, Michigan Technological Univ., School of Engineering, *Houghton, Michigan* 49931

The overall project objective is to improve the applied technology related to the storage, disposal and reuse of water resulting from beneficiation of low grade iron ore. Specifically, the project will: (1) develop basin design and management criteria which recognize the influence of tailings settleability and the effects of hydrological phenomena on pond effluent quality; (2) investigate the physical and transportation characteristics of the supra-collodial particles contained in the tailings basin discharge; and (3) investigate alternative tertiary treatment methods for eliminating the fine particulate materials from the basin discharge with a view toward development of a tertiary treatment system for subsequent demonstrations. The project stems from a current study of mines operated by Cleveland Cliffs Iron Company and associated companies in the Michigan Upper Peninsula. This project will begin in July, 1970, and be completed in October, 1971

3.0190, FEASIBILITY OF REGIONAL UTILITIES FOR MANAGEMENT OF INDUSTRIAL AND MUNICIPAL WASTES

B.M. CONBOY, State Dept. of Commerce, *Lansing, Michigan*

The proposed research plan deals with the economic and institutional feasibility of using regional waste services 'utilities' that would assist industry and municipalities in meeting environmental control standards. The utilities would sell waste management services to industry and municipalities for a fee and use revenue bonds for capital expenditures. The political, institutional and technical factors associated with the design and implementations of a utility approach will be investigated.

3.0192, STUDY OF ECONOMICS OF HOSPITAL SOLID WASTE SYSTEMS

R.G. BOND, Univ. of Minnesota, School of Public Health, *Minneapolis, Minnesota* 55455

Current studies of solid waste handling practices in hospitals have demonstrated a need for a thorough analysis of the economics of such practices. Whereas cost benefit studies in hospitals usually follow the departmental structure of the hospital, solid wastes involve activity in almost every department; therefore, a problem oriented hospital wide study is needed. This study is concerned with the identification, quantificatiom, and evaluation of economic and environmental sanitation constraints of solid waste systems in selected medium size general hospitals.

Present systems involve a large labor force applied to relatively inefficient operation with resulting high costs. Through industrial engineering evaluation techniques efforts will be made to develop more efficient operations - also to determine the critical size of institutions where mechanization, in part at least, is economically feasible and provides an improved system with respect to the sanitation and safety conditions in the hospital.

The study will also attempt to identify the feasibility and benefits of a centralized waste processing system for a cluster of hospitals - just as other hospital operations have benefited from such centralization.

3.0193, EFFECT OF PHYSICAL ENVIRONMENT UPON MANAGEMENT PRACTICES

R.W. BERG, Univ. of Minnesota, Agricultural Experiment Sta., *Saint Paul, Minnesota* 55101 (MIN-16-034)

OBJECTIVE: Investigate variable factors listed below with regard to achieving satisfactory growth and reproduction in turkeys. Variation of floor condition such as the use of wood shavings litter versus slat floors and other possible techniques for the handling of excrement with its attending problems. Effect of bird density upon floor and/or litter conditions as well as upon growth and reproductive characteristics. Relationship of air movement and temperature control upon efficiency of production with variable bird density and floor conditions.

APPROACH: Broad White turkeys will be reared in confinement with automatically controlled light, temperature and humidity to minimize experimental error due to prior environmental

conditioning. Estimates of air movement required relative to various temperatures and bird density in given pens will be made from which experimental variables will be planned for treatment of the birds.

PROGRESS: Turkey breeder hens were housed on three different methods of floor management, - litter floors, slat floors, and cages, - the same as the previous year except one replicate was rotated in an attempt to control broodiness. Rotation did not solve our broodiness problem but produced an indication that the lower hatchability of fertile eggs was present only for the birds held in cages during the holding period. Turkeys moved from cages to litter the hatchability increased 5 percent or almost as high as the controls. This indicates that something in cage management causes a depression in hatchability that is quickly corrected by a transfer to litter. This must be re- checked. Turkeys held either on litter and slats prior to rotation showed no change in hatchability.

3.0195, LABOR REQUIREMENTS FOR PERFORMING FARMSTEAD WORK ELEMENTS

R.E. LARSON, Univ. of Minnesota, U.S.D.A. Agric. Engin. Div., *Saint Paul, Minnesota* 55101 (313-012-B211)

OBJECTIVE: Develop standard times for farmstead labor and operational elements and develop procedures, equipments and structures that will provide optimum labor use in the farmstead operations.

APPROACH: Identify work elements and establish standard times for existing as well as new operational concepts in livestock production. Establish standard times for work elements by time and motion studies on actual farms, on simulated work elements in the laboratory or in pilot type studies or by adaptation from other systems. These standards will be established as part of an ultimate complete system suitable for analysis of any part, or all, of the farmstead operations. The studies will be conducted in conjunction with waste management research and will be directed to the establishment of efficient procedures for handling of feeds, animals, and wastes in livestock production systems, particularly in the area of beef and dairy cattle housing.

PROGRESS: Studies were conducted to evaluate 3 beef production systems. The systems are: (1) conventional open feedlot, (2) confined slatted-floor unit bunk-fed daily, and (3) confined slatted-floor unit self-fed. The two confinement units are over an experimental oxidation ditch. The labor requirements for the open feedlot tend to be higher for inspection of animals and for animal waste handling. The labor requirements between the slatted floor units show little difference as they require the same labor for filling the feed hoppers or storage bins and the time required for feeding daily in the one unit can be utilized for inspection of the animals on essentially the same basis as is required for the similar duty in the self-fed unit. Less labor is required for loading and for hauling wastes from the oxidation ditch under the slatted floor units. However, this will have to be evaluated with other construction and operation costs of the ditch. Labor for inspecting, cleaning, and servicing waterers can be significant with inadequate design. Gain efficiencies of the three systems are indicated by daily gains of 2.95, 2.65, and 3.07 0/day for the three respective units. The feed conversion rates were 794, 799, and 702 pounds/100 0 of grain respectively for the three systems.

SUPPORTED BY U.S. Dept. of Agriculture

3.0196, EVALUATION OF WASTE HANDLING SYSTEMS FOR HOUSED LARGE ANIMALS IN THE NORTH CENTRAL REGION

R.E. LARSON, Univ. of Minnesota, U.S.D.A. Agric. Engin. Div., *Saint Paul, Minnesota* 55101 (901-031-B613)

OBJECTIVE: Develop technology for efficient handling, storing, utilization and disposal of cattle wastes produced in confinement production systems.

APPROACH: Evaluate systems of handling wastes that include storage during cold weather periods when land disposal is not suitable. The investigations will include studies of oxidation ditches. Rotor design, flowspeed, volume ratio and shape are factors to be evaluated. Investigations will be made of means of separating the solids and liquids for separate handling, storage and treatment. The methods studied will include mechanical separation, thermal dehydration, and structural design to provide separation at the point of deposition. Studies will also be made of the confinement structure and equipment to determine design specifications which will minimize the quantity of bedding added to the wastes.

PROGRESS: The use of an oxidation ditch for waste from beef cattle confinement systems has provided odor-free storage with partial treatment. In a trial conducted October 13, 1969 to April 14, 1970, the dissolved oxygen level was above 1 mg/1 throughout the test, so that aerobic conditions were maintained. The trial was started at a loading rate of one animal per 50 cu.ft. of water. The loading rate at the end of 150 days was one animal per 92 cu.ft., leaving a net waste accumulation of approximately .3 cu.ft. per animal per day. The waste production by animals weighing 600-1100 pounds and fed a ration of 90% rolled corn, 7.5% ground hay, and 2.5% supplement averaged 5.1 pounds of dry solids per day per animal. A measurement of the solids in the ditch on the 148th day of the trial indicated the total solids put into the ditch in that period had been reduced 34%. The BOD of the wastes varied within a range of 900 to 2500 mg/1. The COD increased steadily and reached a maximum of 64,000 mg/1. Foam was not a problem in this study as it was permitted to float around the ditch to return to the rotor where it was physically dissipated by the beating action of the rotor.

SUPPORTED BY U.S. Dept. of Agriculture

3.0197, FARM ANIMAL WASTE DISPOSAL

J.A. MOORE, Univ. of Minnesota, Agricultural Experiment Sta., *Saint Paul, Minnesota* 55101 (MIN-12-060)

OBJECTIVE: Evaluate, under Minnesota conditions, the effectiveness of the Pasveer Oxidation Ditch as a means for treatment and partial digestion of beef animal manures.

APPROACH: Beef animals will be confined on slatted floors under cold conditions. The manure wastes from such animals will enter the Pasveer Ditch located directly beneath the animal confinement areas. The rotor of the ditch will be operated on a continuous basis and measurements made on changes in BOD, pH, dissolved oxygen, temperature, suspended solids, volatile solids, nutrient levels and volumes of influent and effluent. Studies will also be made to determine the reduction in solids volume as a result of treatment within the ditch. Such data are needed to determine practical facility size and time intervals between pumping to field soils for final disposal. Construction for the physical facility needed for conducting the above research is completed.

PROGRESS: Research efforts were directed to the study of manure management of beef cattle housed in solid and slatted floor units. An oxidation ditch was used as the treatment storage method. In November, 18 herefords (690 lbs) were placed on each of the following three units: conventional open lot; insulated structure with solid concrete floor (22 sq.ft./animal); and another identical unit with a concrete slat floor. Waste from both confinement units plus water was put into the ditch to provide a loading rate of 1 animal/38 cu.ft. of liquid. After 223 days, the slurry had a total solids concentration of 11.3% and was too viscous for adequate reaeration and circulation. During this test a liquid volume increase had changed the loading rate to 1 animal per 80 cu ft. Results indicate that the batch oxidation ditch system can treat and store cattle manure through a Minnesota winter. Major foaming problems have been eliminated. Studies are presently being continued at a loading of 1 animal/50 cu.ft. Models are being used to study some of the engineering parameters of the system and the fate of pathogens shed with the cattle waste into the oxidation ditch. Handling and storage of waste from 60 dairy cattle is being studied in a 90'x30'x8' concrete tank in Northern Minnesota.

SUPPORTED BY Minnesota State Government - Saint Paul

3.0198, MATERIALS HANDLING SYSTEMS FOR NORTH CENTRAL FARMS

J.H. POMROY, Univ. of Minnesota, Agricultural Experiment Sta., *Saint Paul, Minnesota* 55101 (MIN-12-078)

OBJECTIVE: Establish design criteria of elements for handling agricultural materials.

APPROACH: Three types of housing will be considered: (1) confinement on concrete slab, (2) confinement on concrete slats, (3) open housing with minimal shelter. Twenty head of beef type calves will be fed to market weight under each type of management. Two methods of manure handling within the structure will be considered, (1) soil floor, no bedding, semi-liquid, sloping gutter, and (2) slat floor over an oxidation ditch. Observations will be made of (1) the effectiveness of the oxidation ditch under severe condtions, (2) the conditions on the slats and on the solid floor, and (3) the effect of the oxidation ditch on the environmental conditions, (relative humidity, odor and temperature in particular), in the structure above and on the health of the animals.

PROGRESS: Four trials have been conducted in the pilot-sized units for the study of materials handling and labor requirements of beef cattle under three systems of management, (1) conventional (2) slatted floor total confinement, (3) solid floor, total confinement, slatted gutters. Labor for feeding is limited to that required to fill feeding hoppers every 10-13 days. No labor required for waste handling from the slatted floor. Automated hydraulic flushing of gutter eliminates labor for cleaning solid floor slatted gutter unit. However, flushing water comes directly from the oxidation ditch and contains too much solid material. A holding tank or settling basin is needed to separate solids from liquid for flushing. With the same uniform width slats, 1 1/2' slat spacing stays cleaner than 1 1/4' slat spacing.

SUPPORTED BY U.S. Dept. of Agriculture

3.0199, CROP RESIDUE DISPOSAL

R.F. COLWICK, Mississippi St. University, Agricultural Experiment Sta., *State College, Mississippi* 39762 (MIS-1-200-0308)

OBJECTIVE: Establish design criteria for crop residue disposal machines with primary emphasis on cotton.

APPROACH: Research will be conducted in several phases in order to best utilize funds and personnel available. First phase will be concerned with determining maximum size stalk and root pieces that can be tolerated without disturbing precision and timeliness of planting and weed control equipment in light and heavy soils. Second phase will determine relationship of particle size to rate of decomposition so that size of shredded material in the fall can be related to that remaining at planting time. Third phase will be a study of physical properties of cotton plant and their relationship to disposal forces. This will include such variables as time of shreeding, soil physical condition, mositure of stalk, strength of stalk, root extraction forces, soil tenacity, and angle of root extraction.

PROGRESS: Analysis of data on the 1968 test to determine the influence of length, size, and depth burial on the decomposition rate of cotton stalks was completed. Residue leaf on the surface decayed least, and there was a tendency for better decomposition at the four inch depth of burial than at two inches and six inches, but there were no differences in decayed strength due to length of pieces or soil type. Root sections decomposed slower than any other plant sections, and after decomposition exhibited greater strength than any other plant section for a common diameter. The tendency of residue to interfere with planting accuracy was measured in the field this year by measuring the uniformity of planting depth with several sizes of crop residue. Agreeing with previous soil-bin tests, the 3 inch and 6 inch length residue caused less interference than the 9 inch. Differences in planting depth were harder to detect in the field, but uniformity and rapidity of seedling emergence indicated less interference from the shorter-cut residue. Loosening the surface of the seedbed immediately ahead of planting tended to reduce interference of residue with seed covering. Based on these tests, design criteria for disposal equipment should include provisions for reducing the root and main stem sections to range of 3 inches to 6 inches in length and burial depth of 2 to 4 inches.

SUPPORTED BY Mississippi State Government

3.0200, SOURCES OF TRASH IN COTTON HARVESTING

G.L. BARKER, Delta Branch Experiment Sta., *Stoneville, Mississippi* 38776 (MIS-SUM-0004)

OBJECTIVE: Determine sources of contamination of seed cotton and means for reducing trash in mechanical picking; investigate methods of removing trash during picking operation.

APPROACH: Determine soruces of contamination of cotton lint by using highspeed movies, field tests, and other tracers. Design means of eliminating this trash from the picked sample.

PROGRESS: Laboratory picker investigations have shown considerable trash floating freely or loosely attached to the seed-cotton in the picking zone. Experimental fingers and an air blast system were designed to fit between the picking and the doffing zones in a regular tapered-spindle picker. The fingers and air blast system showed considerable promise in the laboratory but did not work well in the field. In studying the effectiveness of picker basket grates, seven different experiment designs were compared with standard grates. These different designs consisted of rear-ranged expanded metal strips, 1/8' x 1/2' flat strips, 1/4' round stock, and different sizes of expanded metal. The grate made of 1/2 x 1' flat expanded metal, with the diamond turned perpendicular to the flow of cotton proved superior with respect to trash buildup and cleaning ability. A seedcotton cleaning attachment for a tapered spindle cotton picker was developed, using an adaptation of the USDA-developed stick remover in cotton gins. From a mechanical standpoint, the cleaner worked very well and required only slight modifications in the intake and exhaust areas. The total trash content of the seed cotton that had passed through the cleaner was 20 percent less than the trash content of cotton which bypassed the cleaner.

SUPPORTED BY Mississippi State Government

3.0201, DEVELOPMENT OF EQUIPMENT AND TECHNIQUES FOR CROP RESIDUES

J.R WILLFORD, Delta Branch Experiment Sta., *Stoneville, Mississippi* 38776 (MIS-SUM-0006)

OBJECTIVE: Develop, test, and improve equipment and techniques for crop residue disposal.

APPROACH: New shredding devices offered by farm machinery manufacturers will be field tested and an evaluation of their efficiency in total destruction of the old crop will be made. Modifications of present machines will be made and combinations of soil-working equipment and stalk shredding devices will be used in an attempt to incorporate crop disposal operation with primary tillage.

PROGRESS: Further progress was made in developing a low-cost method of removing cotton stalk roots simultaneously with stalk shredding operations. Performance of the 16-inch high-lift sweep used in previous studies was increased by mounting the sweeps on a two-row heavy-duty rotary cutter equipped with three-point hitch. A coulter was also added to reduce lateral movement of the sweeps and aid in centering the machine over the row. Maximum efficiency in removing root stubble was achieved when the sweeps were set to operate at a depth of approximately 3 inches. The machine performed satisfactorily in both dry and moist soil. Over 96 percent of the stubble was removed in field tests on Bosket fine sandy loam. The use of this machine will eliminate one operation with a disk harrow and may help reduce insect populations in cotton fields.

SUPPORTED BY Mississippi State Government

3.0202, CONDITIONING AND CLEANING MID-SOUTH COTTON VARIETIES

V.P. MOORE, U.S. Dept. of Agriculture, Cotton Ginning Research Lab., *Stoneville, Mississippi* 38756 (308-035-C104)

OBJECTIVE: Develop, test, and evaluate methods, practices, and systems for better preserving the inherent quality of cotton during drying, humidifying, and trash removal operations incident to ginning.

APPROACH: Evaluate existing cleaning and newly developed conditioning methods as to their efficiency and effect on cotton quality. Based on these observations and data, investigate new principles which show promise for more effective trash removal and reduce quality degradation. Evaluate under commercial conditions these methods and practices which prove of value in the laboratory prior to making recommendations to the industry.

PROGRESS: Split versus series lint cleaning gave similar grades for each treatment at normal and low moisture levels with no differences in span length and yarn tenacity. Increased clean-

ing efficiency of split stream over single stage lint cleaning is due to reduced loading and not increased combing ratio. Increasing lint cleaner feed rate decreased cleaning efficiency,waste removed, and bale value. Strobe photos show that lint cleaner saws are not loaded uniformly. A linear relationship exists between log of electrical resistance and log of equilibrium moisture regain for lint. A partial vacuum drier proved to be impractical for commercial use but should be useful as a research tool. One 6 cylinder cleaner plus doublestick machines gave best overhead cleaning results. Seed cotton cleaning efficiency decreased as feed rate increased. Picker twists cause grade reduction. Current design of a self-cleaning magnetic separator proved to be unsatisfactory.

SUPPORTED BY U.S. Dept. of Agriculture

3.0203, IMPROVE METHODS, EQUIPMENT & FACILITIES FOR HANDLING WASTE MATERIAL FROM LIVESTOCK MARKETS & FEEDLOT

H.F. MAYES, Univ. of Missouri, U.S.D.A. Transp. & Facil. Div., *Columbia, Missouri* 65201 (TF2-159A)

OBJECTIVE: Develop improved methods, equipment, devices and facilities for handling the waste materials from livestock markets and commercial feedlots.

APPROACH: Conduct engineering studies on livestock markets and commercial feedlots to determine current handling methods and labor and equipment requirements and costs. Evaluate adequacy of handling and disposal of waste materials concerning such problems as odor control, air and water pollution, and meeting Federal, State and local sanitation regulations. Develop operating criteria for more efficient handling of waste materials at reasonable costs.

PROGRESS: On this project, approved during the fiscal year, progress was limited to determining how the livestock marketing industry is disposing of its animal waste materials, current problems in disposing of this waste material, and current problems associated with runoff from holding pens and other uncovered areas. Some of the current disposal methods include dehydration, landfill, spreading on land, and lagooning. In dehydration, some of the existing problems are air pollution, handling required to stockpile and turn, runoff from stockpiles, operation of dehydrators, and excessive power requirements of dehydrators. Landfilling problems include handling of waste material, possible pollution of underground water, and odor. Spreading on land is not practical in some areas because livestock producers are afraid of disease organisms, and because grain producers are concerned with noxious weeds. Where spreading on land is practiced, because the waste material is spread only in late fall and during the spring means the waste material must be stockpiled. Hauling and spreading involves the use of large trucks which can traverse the land only when it is dry enough to support the trucks. Runoff from non-covered pens and other non-covered facilities is entering natural waterways and streams. This runoff is considered a pollutant by many State water pollution boards. The amount of the various pollutants in this runoff must be determined if methods of disposal are to be developed.

SUPPORTED BY U.S. Dept. of Agriculture

3.0204, EFFECT OF PRESYNTHESIZED BIOLOGICAL INTERMEDIATES ON SUBSTRATE UTILIZATION RATES

J.T. NOVAK, Univ. of Missouri, School of Engineering, *Columbia, Missouri* 65202

The proposed research plan involves an investigation into the free energy utilization and substrate removal rates in an anaerobic biological treatment units. In this study, presynthesized biological intermediates will be added to the unit to determine their effect on biological growth rates.

In the first phase of the study, micro quantities of selected amino and fatty acids will be added to methane bacteria to determine if these materials can be assimilated directly by the cells as building blocks for new cells.

The second phase of the study will be to demonstrate the practical application of this technique to field units. Effluent biomass will be destroyed by sonication and the fragmented cell parts recirculated to provide necessary cellular materials for growth stimulation.

Results from this study will be used to demonstrate the fundamental difference between pure substrate laboratory studies and field units receiving mixed organic materials; and may serve as a basis for upgrading present biological waste treatment design criteria.

3.0206, RECOVERY OF MINERAL MATERIALS FROM SELECTED PROCESSING WASTES

A.A. COCHRAN, U.S. Dept. of the Interior, Bureau of Mines, *Rolla, Missouri* 65401

To develop economical processes for recovery and reutilization of metals and minerals from liquid or slurry wastes generated by metal processing and electroplating industries.

Initiate research on extraction and recovery of nickel, chromium, vanadium, cobalt, and other valuable metals from wastes such as stainless steel pickling sludges.

Conclude research on recovery of vanadium, indium, silver, and molybdenum from vanadium extraction plant wastes.

Conclude research on the recovery of metal from cyanide and nitric acid electroplating wastes. Continue investigations on recovery of metals from spent silver electroplating baths, chromic acid etching solutions, and other industrial electroplating wastes. Major emphasis will be on treatment of alkaline, organic-cyanide rack-stripping and etching wastes, followed by the recovery of chromium, nickel, copper, and an aqueous effluent that can be safely discarded to streams.

3.0207, MICROBIOLOGY OF SLUDGE - DNA ANALYSIS AND N2 REMOVAL

R.L. IRGENS, Southwest Missouri State Coll., Graduate School, *Springfield, Missouri* 65802

We are in the process of developing a method whereby DNA may be extracted from activated sludge floc. Having perfected this method, the possibility of using DNA concentration as an estimate of the viable bacterial population of activated sludge floc will be determined. The relationship between the quantity of DNA, the oxygen uptake and the concentration of volatile solids will be investigated.

We are presently comparing denitrification by activated sludge floc at two temperatures, 23 degrees C and 45 degrees C.

Future projects involve the investigation of nitrogen removal in waste treatment at near zero temperatures and the relationship between oxygen tension and denitrification at these temperatures.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0208, FEED AND WASTE REMOVAL STRUCTURES FOR LIVESTOCK

C.M. MILNE, Montana State University, Agricultural Experiment Sta., *Bozeman, Montana* 59715 (MONB00106)

OBJECTIVE: Develop feeding facilities for feeding livestock in a confined area, and to store liquid manure or waste at low temperatures.

APPROACH: Develop feeding facilities for beef cattle using free stall open housing and slotted floors. Assemble necessary equipment to pump liquid manure and to spread liquid manure in the field. Make an economical study of the entire system.

PROGRESS: During the 1968-69 winter feeding period, a stationary chopper was incorporated into the system at the outdoor slotted-floor feed lot. This effort was undertaken as a final

attempt to evaluate the practicability of outdoor slotted floors for beef cattle fattening under severe winter conditions. The 1968-69 winter feeding period was particularly severe with heavy snow and temperatures reaching the -40 F range. During the particularly severe weather, the slot openings plugged up, resulting in manure buildup approximately equal to that in the adjacent solid-floor pens. Despite the severe conditions imposed by the large amounts of bedding and hay in the manure pit, no great difficulty was encountered in cleaning the pit. Techniques have now been developed so that the pit can be satisfactorily emptied using commercially available equipment. Due to the belief of animal scientists that cattle could not tolerate a no-bedding condition under local winter-time conditions, all tests run during the project have incorporated relatively large amounts of bedding. Considerable time and effort was spent in evaluating manure-handling systems in feedlots throughout Montana, preparatory to a major project revision to be proposed in the near future.

SUPPORTED BY Montana State Government

3.0209, EVALUATION OF MEAT ANIMAL HOUSING SYSTEMS IN RELATION TO POLLUTION

T.E. BOND, U.S. Dept. of Agriculture, Agricultural Engin. Res. Div., *Clay Center, Nebraska* 68933 (901-031-B614)

OBJECTIVE. Abate pollution through improved design of meat animal housing systems.

APPROACH. Systems of housing and management will be developed to reduce the pollution potential of livestock production, and increase the efficiency of animal waste handling and disposal. The influence of such factors as surface materials, floor slope, degree of shelter enclosure, animal space, feeds, feeding methods, ventilation, and climate will be investigated in systems ranging from open feedlots to completely enclosed confinement housing. Evaluation will be measured by the amounts of dust odors, insect pests, runoff and subsurface water pollution, and by animal health and productivity.

PROGRESS.

SUPPORTED BY U.S. Dept. of Agriculture

3.0210, DAIRY HERD MANAGEMENT

R.D. APPLEMAN, Univ. of Nebraska, Agricultural Experiment Sta., *Lincoln, Nebraska* 68508 (NEB-13-035)

OBJECTIVE. Develop supplemental record-keeping programs to complement current DHIA programs. Compare systems of livestock housing and feeding, including waste disposal and disease prevention. Study impact of mechanization on labor utilization.

APPROACH. Evaluate devices for milk weighing, sampling and testing which may meet present DHIA standards. Each device will be tested on two consecutive milkings of at least 25 cows. The project leader will work closely with one or more commercial DHIA computing centers in the development of a suitable mechanized record-keeping systems encompassing the health and reproductive status of both the young and producing stock. Daily milk weights and weekly milk composition data will be obtained. Individual calf shelters for raising calves outdoors will be compared to conventional calf-raising systems utilizing individual pens in a controlled indoor environment. Various feeding programs, methods of disease control and economic consideration will be included. Milking vacuum level, milking vacuum stability, type of liner used, length of liner life, pre-milking sanitation practices, and teat-dipping after milking will be investigated.

PROGRESS. Three different milk metering and sampling devices (Milk-O-Meter, Tru-Test, Waikato) were evaluated. The observed accuracy of two Tru-Test meters, expressed as a percentage of true scale weight, averaged 99.5 and 100.0% and were recommended for approval. Weekly milk weight milk fat data were collected from fresh cows in three different herds to determine the influence of time from freshening to first test on the accuracy of DHIA records. Herd differences are apparent, with positive errors in estimated fat production occurring in all herds when cows are first sampled within 25 days of freshening. Radiographs of the teat streak canals of 105 lactating cows were obtained to determine the factors influencing anatomical changes of the teat-end and its importance in the incidence of mastitis. Increasing age and advancing stage of lactation resulted in dilated teats. The correlation of these traits to either rate of milk flow or udder health was low. Studies indicate that early weaned calves can be successfully fed once daily with milk replacer or with cold milk. Colostrum was superior to whole milk.

SUPPORTED BY U.S. Dept. of Agriculture

3.0211, INFLUENCE OF CERTAIN HOUSING AND MANAGEMENT REGIMES ON CONFINEMENT REARING OF GROWING FINISHING PIGS

R.D. FRITSCHEN, Univ. of Nebraska, Agricultural Experiment Sta., *Lincoln, Nebraska* 68508 (NEB-42-001)

OBJECTIVE. Compare the effects of open versus closed growing- finishing buildings in a one-and-two-unit production system; determine the amount of slotted floor required for optimum performance; determine optimum pen size and shape; evaluate economically the implications of several confinement systems; observe and study manure disposal procedures; evaluate ventilation systems.

APPROACH. Insulated, environmentally regulated buildings are compared with uninsulated, semi-open front buildings. Four buildings are of concrete block and two are precast concrete panel construction. Three replications of pens with 25, 50, 75 and 100 percent of total pen floor area slotted are compared. Environment (temperature, humidity, air flow) in each unit will be measured by sensing equipment. Economic components (i.e. electricity, gas, labor) will be measured per unit. Carcass data including bone breaking strength are measured.

PROGRESS. The completion of four additional growing-finishing (G/F) research production units and utility building in May 1969 brought the building total to seven six research units plus utility building. A test including 480 G/F swine (Aug. 8-Dec. 12, 1969) indicated that swine grown in an environmentally regulated (ER) unit do not have a greater rate of gain expression than those in an unheated, uninsulated modified open-front (MOF) unit. However, pigs grown in an ER environment had a 6.2 percent improvement in feed efficiency. No difference was noted between pigs grown to 100 lbs. to market wt. swine grown in semi-exposed confinement gained slower (8.1 %) and required more feed (12.3 %) than those in an ER unit. The decreased response in performance is largely thought to be due to more severe ambient weather. The slat to solid floor types studied revealed a slight linear response in favor of less slatted area in the open and modified open front units. Tissue studies indicate that stomach tissues do undergo unfavorable changes such as ulcers when grown under the described conditions. Lung and metatarsal bones are also being used as response criteria.

SUPPORTED BY Nebraska State Government

3.0212, WASTE MANAGEMENT, CONTROL, AND DISPOSAL IN MIDWEST BEEF FEEDLOTS

C.B. GILBERTSON, Univ. of Nebraska, U.S.D.A. Agric. Eng. Res. Div., *Lincoln, Nebraska* 68503 (901-031-B608)

OBJECTIVE. Develop beef feedlot criteria for design for economical waste management and disposal with effective pollution control.

APPROACH. Investigate systems of animal waste disposal that can be adapted to existing feedlots to prevent contamination of water by the run-off. The investigations will include studies of hydraulic settling channels or basins from which solids can be removed frequently, basins of larger area and longer retention to allow settling out of suspended solids for more infrequent removal and with the liquids siphoned to an evaporation pond. Studies will be made of the use of reverse slope dirt lots with feed bunks and apron located on the low side. In this type layout the apron will serve as a collection and clean out area and will be connected to a liquid control system. The method and equipment necessary for mechanical management of the wastes during dry periods will be also included in these studies.

PROGRESS. Solids Accumulation on Outdoor Feedlots: Dry matter cleaned from outdoor feedlots averaged 1.42 and 2.26 tons per acre-day for lots with animal densities of 200 and 100 sq. ft. per animal, respectively. About 34% of the dry matter was volatile. Total N averaged 29 lb. per ton dry matter. Runoff

Quantity and quality of runoff appeared to be more dependent on rainfall than feedlot slope or animal densities. An estimating equation based on all treatments was Runoff 0 0.531 (Precipitation) - 0.135. Winter thaw runoff concentrations were about 10 times the rainfall-runoff concentrations. Rainfall-runoff transported an average of 1.6 tons dry matter per ac-in. About 50% of the transported material was volatile. N and P transported averaged 100 and 13 lb. per ac-in., respectively.

SUPPORTED BY U.S. Dept. of Agriculture

3.0213, MANAGEMENT OF CATTLE FEEDLOTS AND ANIMAL WASTES FOR CONTROL OF SOIL WATER AND AIR POLLUTION

T.M. MCCALLA, Univ. of Nebraska, U.S.D.A. Soil & Wa. Cons. Div., *Lincoln, Nebraska* 68503 (SWC-026-DLI-2)

OBJECTIVE. Measure the magnitude of soil, water and air pollution from existing systems of cattle feedlot management and develop scientific principles and engineering designs for the effective control of pollution by runoff and deep percolation of water, and volatilization into the air, and the efficient disposal of animal wastes on agricultural land.

APPROACH. Laboratory and field investigations, often on a small watershed basis, will be conducted to determine the extent of pollution of runoff and ground water by organic substances, phosphate, nitrate, and harmful organisms on the range of site and feedlot management conditions now used. New systems will be designed and tested for more effective control of runoff and management of the water balance of the feedlot for on-site disposal. Field studies will be conducted to determine how much and when animal wastes can be applied to soils to effectively use the waste as a resource for crop production without contaminating soils and runoff and underground water.

PROGRESS. Four commercial cattle feedyards in eastern Nebraska have been completely instrumented to measure precipitation and runoff. Vacuum lysimeters and access cylinders have been installed to measure quantity and chemical quality of percolate. One feedyard was bench- terraced to evaluate the practice for retention of runoff. At Gretna, on a 5% slope, about 0.5 inch of rain is needed to initiate any runoff, but 1 inch is needed if the surface is very dry. Most of the turbidity and offensive odor and taste of runoff can be eliminated by treatment with alum and a cationic polyelectrolyte. On a flat, uncleaned feedlot no percolation of nitrate into the shallow water table apparently occurs. High methane and CO(2) concentrations occur in the soil air under the feedlot, but not under cultivated fields at the same depth. Preliminary data show that ammonia, amines and organic acids volatilize from feedlot surfaces. Comprehensive data on composition of feedlot runoff from different management systems were obtained.

3.0214, UTILITIES IN PERMAFROST FOR MILITARY INSTALLATIONS

S.C. REED, U.S. Army, Cold Reg. Res. & Engin. Lab., *Hanover, New Hampshire* 03755

Technical Objective. To develop new and improved criteria for design and construction of utilities for military installations in permafrost areas, including water, fuel and electric supply, fire protection and waste treatment and disposal systems.

SUPPORTED BY U.S. Dept. of Defense - Army

3.0215, EXPERIMENTS TO DETERMINE THE EFFECTIVENESS OF PHOSPHATE REMOVAL BY MEANS OF THE MOVING BED FILTER

G.R. BELL, Johns Manville Corporation, *Manville, New Jersey* 08835

The effectiveness of the Moving Bed Filter will be determined for the removal of suspended solids and phosphate removal as compared to conventional methods. The Moving Bed Filter (15,000 gpd) will be installed at a typical waste treatment plant to optimize the flocculation and filtration procedures for phosphate and solids removal. Design and engineering data will be developed for a fullscale installation. Estimates of the capital and operating costs for various sizes of plants also will be made.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

3.0216, VOLUME REDUCTION AND STABILIZATION OF WASTES FROM SWINE

H.E. BESLEY, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (901-031-B615(CA))

OBJECTIVE. Develop technology for the use of composting methods for volume reduction and stabilization of wastes.

APPROACH. Determine characteristics of the wastes from the animals, incidental bedding, and feed. Characteristics will include moisture content, plastic materials, metals, glass, bacteria, molds, fungi, BOD, nitrogen and others as necessary. Studies will be made of the biological and chemical changes occurring in the process as influenced by various characteristics. Evaluations of handling methods for both the raw wastes and the processed material will be made in a search for technology for reducing the potential of the wastes to pollute the surrounding air and water. Utilization and/or disposal of the processed materials will be the aim of studies of its use for lawn or field application or of its disposal in sanitary landfill.

PROGRESS. A Roto-Shredder was obtained and tests started August 18, 1969 with two windrows of swine waste 12 feet wide, 6 1/2 feet high and 120 feet long. This trial was designed to develop the techniques of composting hog wastes and to become familiar with the operation of the machinery. Windrows were turned twice a week for the first two weeks, then once a week through December 30. The original material was high in moisture content. Temperatures were slow to rise during this period. Heating occurred in all parts of the windrows through the third and fourth weeks, rising to 150 F. This temperature persisted until turning was stopped December 30 (17 weeks). Characteristics of bacteria, fungi, etc., were not observed during this trial; analyses of these characteristics are planned for the next trial. The odor of the original material was quite offensive. This changed afterthe fourth and fifth week to a musty odor. Later in the process the material took on a dark brown color with an earth-like odor. When turning was stopped (after 21 weeks), the windrows were 9 feet wide, 2 1/2 feet high and 120 feet long, showing a reduction in volume. The nonbiodegradable materials, such as plastics, still create a problem and a means of screening and disposing of them must be determined.

SUPPORTED BY U.S. Dept. of Agriculture

3.0217, POULTRY MANURE DISPOSAL BY PLOW FURROW COVER

H.E. BESLEY, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00903)

OBJECTIVE. Explore the limitations of the plow-furrow-cover method of disposal of poultry manure and to investigate the pollutional effects upon the ground water and the soil.

APPROACH. Present equipment used in the plow-furrow-cover method will be reelevaluated and modified or new equipment developed for use in this project. The amounts, frequency of application, and length of time that poultry manure may be disposed of in the soil will be disposed of in the soil will be determined and the chemical, physical and biological changes occurring in the soil will be measured. Factors which limit the prolonged use of soil as the disposal medium will be evaluated and the performance of soil as disposal media will be correlated with loading regime and soil characteristics.

PROGRESS. The plow-furrow-cover (PFC) method of waste disposal is a technique for incorporating slurries and semi-solid wastes into the aerobic layer of the soil in a relatively odor-free and pest-free manner. To apply wastes by the PFC method, various components of equipment have been developed and demonstrated. Poultry manure was PFC applied to test plots of Freehold loamy sand in amounts equivalent to 0, 15, 30 and 45 tons of dry solids per acre. The soil was not cropped. An analysis of lysimeter samples showed downward movement of elements of 36 and 48 inch depths without high concentrations in 4 to 7 months. However, 12 to 15 months after the application some high nitrate,

sulfate and TOC concentrations were measured down to the 48 inch depth. In a laboratory examination of poultry manure samples obtained from commercial farms it was observed that approximately 30% of the samples contained Salmonella.

SUPPORTED BY New Jersey State Government - Trenton

3.0218. REMOVAL OF PHOSPHATE FROM WATER BY ALUMINUM AND IRON

P.H. HSU, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00085)

OBJECTIVE: Study the reaction mechanism between phosphate and aluminum or iron, and define the optimum conditions for removal of phosphate from water.

APPROACH: Using wet chemical and diffraction techniques, studies will be made of the nature of the phosphate-removing cations (Al or Fe), their concentration, the concentration of phosphate, ratios among these, various sources of cations, the presence of other components, and additional factors.

PROGRESS: The ultimate objective of this project is to develop an effective and economic process for removing phosphate from water and sewage by aluminum or iron. The research activity was started from a study of several simple systems containing AlCl(3), NaH(2)PO(4) and NaOH only, with an objective to understand the fundamental reaction mechanism between aluminum and phosphate. Experimental results indicate that positively charged hydroxy-aluminum polymers are the species accounting for the precipitation of phosphate. Phosphate was effectively and immediately precipitated from solution when the polymers were completely neutralized of their positive charges by phosphate ions, but the precipitation of phosphate was much less effective either prior to or after this point. On the basis of the information, the dosage of aluminum must be critically controlled in any practical process of phosphate removal. This trouble, however, can be overcome by the addition of sulfate or kaolinite as coagulation aid. Montmorillonite can also be used as coagulation aid, but it is difficult to reduce the final phosphate concentration to lower than 2 ppm. Fluoride, on the other hand, indicates detrimental effects.

SUPPORTED BY New Jersey State Government - Trenton

3.0219. SOLID AND LIQUID WASTES

A.J. KAPLOVSKY, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00531)

OBJECTIVE: Characterize and identify the microorganisms that initiate floc formation during an activated sludge start-up period.

APPROACH: Study to establish the chemistry of colorimetric reaction between phenolic compounds and 4-aminoantipyrine.

PROGRESS: Study indicated that activated carbon adsorption data from wastewater and plant effluents do not fit either Freundlich or Langmuir isotherms but data allowed for interpretation by semi-log method. Influent organics are more efficiently removed than effluent organics, and reduced organics more readily removed than oxidized organics. The role of flow rate on benthal oxygen demand was investigated and found to be a complex relationship between oxygen supply effects, detention time, and turbulence. Composting will be carried out in continuous steady state, bench composter. Will monitor and measure temperature, air flow, oxygen utilization, carbon dioxide evolution and substrate feeding rates. At steady-state microbial population study will be made. Gravitational electrodialysis extended to industrial wastewaters. Technique did not result in detailed information but technique used in conjunction with adsorption, chemical treatment with lime, ion exchange and reverse osmosis can provide picture of wastewater characteristics. Work underway to determine effect of wastewater treatment processes on molecular weight distribution of wastewater soluble organics by Sephadex filtration.

SUPPORTED BY New Jersey State Government - Trenton

3.0220. SOLID AND LIQUID WASTES - TREATMENT

A.J. KAPLOVSKY, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00532)

OBJECTIVE: Determine chemical composition of substrate in bulking of activated sludge; biodegradability of commercial and experimental detergents and effects of same on operation and efficiency of sewage treatment process and plant; evaluate principles of simultaneous enzymic adaptation and induction and repression of enzymes in mixed bacterial populations involved in waste treatment process.

APPROACH: This work will be performed in model systems in laboratory and in nearby municipal waste treatment plants.

PROGRESS: Disc system exploits activities of attached biological growths on closely spaced rotating discs alternately submerged in wastewater and exposed to air for high degree removal of organic matter and oxidation of NH(3)-N. BOD and SS reductions exceed 90% after 1 hour contact time. Chlorine demands low (1 mg/1) after 10 stages. Surfactants 1 mg/1 after 8 stages. Die-off studies reveal importance of moisture and temperature in relationship to persistence of Salmonella in poultry manure. Pathogen isolated from dried excreta after 148 days but not found in wet excreta at 30 C after 8.6 days. Changes induced by ionizing radiation will be evaluated for enhancing subsequent solids waste handling processes. Sludge digestion - analysis system designed, constructed and tested. Studied factors affecting persistence of Salmonella in avian residues from poultry operations. Initial increase in organisms observed upon addition. Die-off curves show organisms supported longer in turkey and duck excreta as compared to chickens. Aerated manure slurries studies through sludge age, sludge volume index and volumetric loading. Only volumetric parameter of cu.ft. of aeration tank capacity/0 BOD applied was responsive to operational changes. Long term poultry manure soil decomposition followed through nitrogen transformations. Data showed 60% nitrogen loss after 214 days. No nitrite or nitrate in soil observed. N(2) loss most likely gaseous.

3.0221. HANDLING AND DISPOSAL OF POULTRY MANURE

C.H. REED, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00568)

OBJECTIVE: Determine a practical and economical method of disposing of poultry manure by using soil as active stablizing agent.

APPROACH: One of the first methods to be investigated will be a sanitary land-fill method, or perhaps modifying it to some type of soil covering technique.

PROGRESS: During the last 5 years the testing and modification of 5 prototypes of tank trailers have established the performance requirements and many of the detailed specifications for farm equipment for the plow-furrow-cover method of waste disposal. Farm tractors are the power source for these two-wheel tank trailers, plow being mounted on either the trailer or tractor. Each of the tank trailers has limitations on the solids content of the liquid manure which it can load or unload. The most versatile unit for unloading is not equipped to self-load. Field testing was continued this year and specifications are nearly completed for this type of equipment. Plans have been initiated for a self-propelled highway transport with interchangeable components which will function as follows: 1) Load or unload any biodegradeable slurry or semi-solid waste with up to 30% solids; i.e. poultry or animal manures with bedding, municipal sewage sludge, or industrial waste sludge. 2) Plow-furrow-cover. 3) Inject beneath sod. 4) Spread on the land surface. It is hoped that this new component can be integrated with many waste disposal systems in which waste is stabilized in the soil and utilized in plant growth cycles.

3. SOLID WASTE MANAGEMENT

SUPPORTED BY New Jersey State Government - Trenton

3.0222, CIRCULAR DAIRY BARN

M.E. SINGLEY, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00570)

OBJECTIVE: Construct and study in operation a self-feeder silo- milk production center for 40 animals, study performance of dairy animals when self-fed from silo containing a specification feed, and study the nature of forage production and supplementation required for specification feeds.

APPROACH: Construct milk production center with 18-foot diameter silo, 60 feet tall; a 6-foot wide feeding platform; a 7-foot wide manure alley and free stalls 7 feet long contained in a circular building 60 feet in diameter. Records will be maintained on labor requirements in the center, power requirements and bedding requirements. Manure disposal system will be constantly evaluated. Feed consumption will be recorded daily and related to milk production. Yield of forage crops will be recorded and analysis of the forage will be made prior to storage and supplements added as necessary to meet feed specification. When fed, each forage will be again analysed to determine feed value losses.

PROGRESS: The barn was occupied on January 9, 1969. Most systems have worked well. Operation of the self-feeder silo has not been completely satisfactory. Very short cut alfalfa haylage with a high rate of corn meal additive cannot be supported. Corn silage has performed fairly well. Adjustments of the length of cut of the material and of the support elements are being made to resolve these problems. Measurements of the loads on these elements are being made. Several techniques of flushing the liquid manure have been tried. This system has been improved by increasing the height of the gates from 12 to 18 inches. Keeping the trench full to an 18-inch depth with water and allowing manure to float off over the top seems to work well. The storage tank has been emptied several times and the emptying system seems satisfactory. The ventilation system has performed well. Temperatures are being monitored. Condensation only occurs when the animals return to a cold barn. In the summer months, ambient temperatures in the barn are maintained within 2 F. of outside air temperature. The air conditioning has not been installed.

SUPPORTED BY U.S. Dept. of Agriculture

3.0223, DISPOSAL AND UTILIZATION OF DAIRY AND POULTRY MANURES BY LAND APPLICATION

J.E. STECKEL, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00064)

OBJECTIVE: Develop and evaluate disposal and utilization systems for land application of treated and untreated dairy and poultry manure that will minimize the pollution of water, soil and air.

APPROACH: Study the application of liquid poultry manure by plow- furrow-cover and sub-sod injection methods; analyze soil samples for mobility of Ca, Mg, Na, K, NH(4), Cl, NO(2), SO(4), PO(4) and carbon thru the soil profile; determine changes in soil physical conditions; determine the decomposition rates under various loading and different temperatures; and determine the survival of salmonella in soil and seek information to minimize the dissemination of this organism through disposal by land application.

PROGRESS: Poultry manure was PFC applied 6 to 7 inches into Freehold loamy sand soil (20% clay in the B horizon). The soil was not cropped. Soil-water was sampled with suction lysimeters. Samples collected on 10/24/68 (131 days and 17 inches of rain after PFC) show a downward movement of K, Ca, Mg, Na, NO(3) NO(2)-N, Cl, and SO(4). Increased concentrations of these elements were found at 36 inches soil depth but not at 48 inches. Subsequent soil-water samples taken on 7/1/69 (391 days and 50 inches after PFC) show considerable increase in concentrations at 36 and 48 inches. NO(3) NO(2)-N concentrations on the zero, 15, 30, and 45-ton water-free poultry manure treatments were 1, 90, 290, and 700 ppm at 36 inches and 10, 250, 590, and 450 ppm at 48 inches respectively. The amount of element dissolved in the soil water in an acre for 5 soil depths has been calculated and summed for the 9 to 48-inch soil depth. For the 7/1/69 sampling, the sums of 25, 215, 590, and 1090 pounds of nitrogen (as NO(3) NO(2)/acre) were found dissolved in the soil water in the 0, 15, 30 and 45-ton PM treatments respectively. Similar trends exist for K, Ca, Mg, Na, Cl, and SO(4). Disposal of large amounts of poultry manure into soil by PFC has caused large increases in the concentrations of elements in the soil water. Soil-water samples will be taken next year to determine when or if the element concentration reaches a maximum and starts to decrease.

3.0224, REMOVAL OF BOD AND NUTRIENTS BY BIOLOGICAL SLIMES

W.N. TORPEY, Rutgers the State University, Graduate School, *New Brunswick, New Jersey* 08903

The objective of this proposal is to exploit the activities of attached biological growths on closely spaced rotating disks alternately submerged in sewage and exposed to air for high degree removal of organic matter, nitrogen and phosphorus. It is proposed to utilize a series of such units for sequential specialized populations. It is expected that neither artificial aeration nor secondary sedimentation will be necessary by virtue of the fact that the biological growths will not be allowed to accumulate to great thickness and will, therefore, not slough off but instead they will be removed at will after they have reached the logarithmic stage of growth.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0225, WEST COXSACKIE PROJECT - HIGH-PERFORMANCE BIO-TREATMENT OF MUNICIPAL SEWAGE

C. BEER, State Dept. of Env. Conserv., *Albany, New York* 12205

The following process concepts will be investigated: aerated surge tank ahead of plant, two-stage activated sludge, including an up-flow intermediate settler, two-stage final settling, shallow multiple-tray settling, a batch process of aerobic sludge stabilization, chemical oxidation (by chlorine) of primary sludge, biochemical precipitation of phosphates within the activated sludge system.

The project will be conducted in an experimental sewage treatment plant of 120,000 GPD capacity using domestic sewage from a state penal institution. The project was started in 1967 and should continue through 1974. The site of the project is West Coxsackie, New York.

SUPPORTED BY New York State Government - Albany

3.0226, A PRESSURE SEWER SYSTEM DEMONSTRATION

J.G. CARCICH, State Dept. of Env. Conserv., *Albany, New York* 12205

The major purpose of this project is to demonstrate the feasibility of a pressure sewer system. Previous work by the American Society of Civil Engineers under a Federal Water Pollution Control Contract has been devoted to the development of design criteria, construction methodology, installation techniques, and a grinder-storage-pump unit. This work has been completed and a demonstration of the entire system is now necessary.

The demonstration will consist of having pump-storage-grinders fabricated and installed in twelve homes located in close proximity one to the other and connected to a common pressure sewer line. At a point downstream of the test area, the pressure line would discharge into a gravity system. By the end of June 1970, the installation will be completed, the system will be operated for a one year period to observe its feasibility. If the system proves feasible, it will be possible to sewer many other areas at a reduced cost and to sewer some areas which were previously unsewerable.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0227, CHEMICAL-PHYSICAL WASTE TREATMENT PLANT DEMONSTRATION

L.J. HETLING, State Dept. of Env. Conserv., *Albany, New York* 12205

A new chemical-physical process to treat wastewater, remove phosphorus and produce a reuseable water will be demonstrated. A 7 gpm trailer mounted pilot plant of the process will be constructed and tested by Ecolotech, Inc. for the New York State Department of Health. The pilot plant will employ lime coagulation of raw wastewater, CO sub 2 neutralization, activated carbon adsorption and sand filtration. The pilot plant will be used to obtain design data for a full scale 1.7 MGD chemical physical waste treatment plant which is anticipated to be built in Waterford, N. Y. The pilot plant may be moved to various municipalities for testing on their wastes. Several experimental methods to remove nitrogen will also be tried.

The contract for the pilot plant with Ecolotech, Inc. was initiated in April, 1969. The first phase of operation of pilot plant should begin in September, 1969 at New Rochelle, N. Y. and at Waterford, N. Y. by June, 1970.

SUPPORTED BY New York State Government - Albany

3.0228, THE BIOCHEMISTRY OF ANAEROBIC DIGESTION

J.S. JERIS, Manhattan College, School of Engineering, *Bronx, New York* 10471

Investigations in anaerobic digestion have shown that the process has great potential for treatment of concentrated complex wastes. Yet, the process is not being used to its maximum potential because of a lack of fundamental knowledge of its microbiology and biochemistry.

The general objective of this proposal is to explore further the basic biochemistry in order to determine the general pathways involved in the anaerobic microbiological breakdown of various pure organic compounds which are constituents of complex wastes. Some of the compounds under study include propionic acid, lactic acid, succinic acid, glutamic acid, glycine, and oleic acid.

The role of intermediate compounds such as acetic, propionic and butyric acids is under study as thet appear to be very important metabolic products.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

3.0229, CELLULOSE DEGRADATION IN COMPOSTING

J.S. JERIS, Manhattan College, School of Engineering, *Bronx, New York* 10471

Solid waste disposal has become a problem of great magnitude in urban areas throughout the United States. As present disposal methods are often inadequate or uneconomical, modifications, as well as new innovations will be necessary in order to solve the present and long- term requirements of our growing society. As composting offers an end product which could have monetary value, the process needs a close evaluation. In conjunction with a reduction of the time required to obtain complete stabilization, it is anticipated that the process economics would be greatly improved. In this investigation, an attempt will be made to learn the optimum environmental conditions required by composting microorganisms. As the amount of paper, which is primarily cellulose, has become a major constituent of refuse, the study of the microbial degradation of the biologically resistant material will receive major emphasis. By delineating the environmental conditions maximizing the rate of degradation in composting, the process can be optimized and should yield a more efficient as well as a more economical operation.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0230, ACID EMULSION BREAKING - ACTIVATED SLUDGE FOR BAKERY WASTE

H.A. SCHLESINGER, Ebinger Baking Company, *Brooklyn, New York* 11226

A 22 month demonstration program is planned which includes the following objectives: 1. Implement pre-construction research and development conclusions a. Finalized design of operable plant; b. Construct operable plant; c. Initiate operation of finalized plant; d. Evaluate plant operations. 2. Define operating parameters for optimization of process and treatment plant operations. 3. Provide operating data to produce an effluent suitable for, at maximum, injection into ground-water supplies per Suffolk County standards. 4. Develop critical criteria for treatment of a heavily loaded waste of high solids content for, at maximum, discharge into ground waters utilized for water supplies. 5. Determine on an operating scale the amounts and optimum disposal methods of the solid wastes produced. 6. Make all technical operating data available in 'Summary Technical Report' for utilization and guidance of other planning, designing or operating industrial wastewater plants for upgrading the quality of bakery wastewaters to various degrees.

Work will be performed at the Ebinger Baking Co. plant site at Lot No.5, Melville, Long Island, New York

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0231, DESIGN OF WASTE TREATMENT FACILITIES BY COMPUTER

J.J. DEGROAT, Technicomp Incorporated, *Great Neck, New York* 11021

This project contract was undertaken to explore the possibility of automating the design of a municipal sewage treatment plant. The word automating is here used to indicate that complete construction plans and specifications should be prepared on digital computing and automatic drafting machines. Included within the computer programs to be developed will be the design equations governing the various process kinetics and associated unit operation designs. The majority of programming will be in Fortran IV for the IBM 360/65 or the CDC 6600. Automatic drafting will be undertaken using the Universal Drafting Machine and the Orthomat Action Language. The project was started on July 1 1969 and should terminate on December 31, 1970.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0232, POULTRY WASTE DISPOSAL AND ASSOCIATED ODOR CONTROL

W.E. BURNETT, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (032906990133)

OBJECTIVE: Identify factors which cause objectional odors in manure and ways and means of controlling them.

APPROACH: Bacteriological studies will be made of organisms that may be responsible for undesirable odors.

PROGRESS: A number of odorous compounds in poultry manure have been identified by chemical and organoleptic tests. The organoleptic tests that have been conducted indicate that the odor of accumulated poultry manure is a complex mixture of hydrogen sulfide, ammonia, diketones, mercaptans, sulfides, organic acids (C(2) - C(5)), indole, and skatole, and as yet other unidentified compounds. Anerobic microbial activity in poultry manure has been shown to be an important contributor of these obnoxious odors through the accumulation of sulfate reducing bacteria (Desulfovborio), methane-producing bacteria and an increase in concentration of volatile organic acids that seem to parallel the microbial population increase. To control odors, 44 masking agents, conteractants, deodorants and digestive deodorants were tested. Only 1 (a masking agent) seemed to merit further investigation and in this case the cost seemed prohibitive. Aeration of liquid manure seemed to reduce odor somewhat, but not to a degree that would be completely acceptable.

SUPPORTED BY U.S. Dept. of Agriculture

3.0233, WASTE DISPOSAL

N.C. DONDERO, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00170)

OBJECTIVE: Define microbiological and environmental conditions most conducive to solubilization and voltilization of poultry waste products.

APPROACH: Poultry manure will be lyophilized to afford a constant starting material as well as to facilitate a comparison of results in the course of the study. The quantity of water-soluble organic and inorganic material and water insoluble organic and inorganic material will be estimated by appropriate methods in

the lyophilized manure. Complex microflora obtained from a spectrum of environments and pure starter cultures will be coupled with diverse physical conditions such as water content, pH value, degree of aerobiosis and temperature under laboratory conditions. After these experimental treatments the aforementioned quantities of water-soluble and water-insoluble materials will be estimated and compared with base line values. These comparisons will reflect influence of variables upon solubilization and volatilization of the manure components.

PROGRESS: Microbial and chemical changes taking place in stored poultry manure have been studied with particular reference to the generation of odors. An organoleptic test ('matching standards') was developed to evaluate odor control substances for use with stored poultry manure. Making agents were most effective, deodorants less so, and enzyme preparations least so. Preliminary field trials indicate cost of deodorant treatment to be about 14 cents per hundred gallons of liquid manure when used prior to field spreading. In laboratory tests, manure held without added water produced less odor than liquid manure. The decomposition of uric acid by bacteria caused the formation of significant amounts of ammonia. Only a part of the sulfide was formed by sulfate-reducing bacteria. Odorous short-chain fatty acids (C(2)- C(5)) accumulated, probably as the result of the metabolism of high numbers of clostridial bacteria. The concentration of fatty acids increased to 2000 mg/l in 16 days and declined steadily. Methane- forming bacteria were present in small numbers until rapid multiplication began after 28 days. The odor intensity of stored liquid manure increased steadily during the 30 days of observation.

3.0234, HANDLING AND DISPOSAL OF POULTRY WASTES

A.G. HASHIMOTO, State University of New York, U.S.D.A. Agric. Eng. Res. Div., *Ithaca, New York* 14850 (901-031-B611)

OBJECTIVE: Develop equipment and management procedures to reduce the pollution hazards from poultry wastes in caged layer egg production in the Northeast.

APPROACH: Determine the components in poultry wastes that cause noxious odors and evaluate masking agents that will reduce, eliminate or cover them. Feasibility studies will also be made of alternate techniques that will fit into production systems and develop the engineering technology of the most promising of these. Some of the alternates are waste treatment in lagoons and oxidation ditches; land disposal by spreading or deep plowing and storage methods that will permit holding the wastes when conditions are unfavorable for land disposal. Immediate, urgent and long range corrective measures to control pollution will be included.

PROGRESS: Preliminary investigations have shown that aeration lowers the odor and nitrogen levels in chicken manure slurries. The preliminary investigations have also shown that if high nitrogen removals are necessary, a two-stage waste disposal system would be necessary. The first stage would consist of an aeration unit to minimize the production of odorous gases and convert complex nitrogenous compounds to ammonia. The second stage would be an ammonia desorption unit to raise the pH and strip ammonia gas out of the slurry by aeration. The limiting phase of the system outlined above is the rate of ammonia stripped out of the manure slurry. Therefore, the initial emphasis of this research project is to investigate the factors affecting the rate of ammonia being stripped out of poultry manure slurry. A theoretical equation has been developed which indicates that temperature, pH and air flow rate have a significant affect upon the rate of ammonia stripping. The evaluation of the above mentioned factors are currently being investigated.

SUPPORTED BY U.S. Dept. of Agriculture

3.0235, SYSTEMS FOR ALLEVIATING ODORS FROM POULTRY WASTES

D.C. LUDINGTON, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (901-031-B612)

OBJECTIVE: Through preliminary research studies and cost analyses determine systems of poultry manure disposal having the most promise for successful incorporation into poultry production enterprises, particularly where odors are a major problem.

APPROACH: Study poultry manure management and handling to reduce odor production by investigating thermal methods of removing moisture and low-volume direct aeration for oxidation. Investigate wet scrubbing and filtering of exhaust air from ventilation systems to remove odorous materials and screen agents to mask obnoxious odors.

PROGRESS: Mechanical devices which will promote drying of the manure before the manure enters the pit are being tested. Manure will not dry enough when the manure drops directly into the pit to successfully control odors. Frequent removal removes manure before bacteria have a chance to produce odors. The effects of air velocity on moisture removal have been studied and the data is now being compiled and analyzed.

SUPPORTED BY U.S. Dept. of Agriculture

3.0236, POULTRY WASTE HANDLING SYSTEM DESIGN

D.C. LUDINGTON, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (901-031-B617(CA))

OBJECTIVE: Develop technology for a complete system to handle, treat and store poultry manure utilizing the removal of moisture as a method for control of odors.

APPROACH: Screens and sloped plate devices will be studied as a means of enhancing waste drying before dropping into the collection pit. The screen opening and configuration and the plate angle and configuration will be evaluated as they affect the flow of drying air in and around the manure. Moisture content of the manure and odors emanating from it will be the standard used to measure effectiveness. Commercial design scrapers and experimental designs will be evaluated to determine the effectiveness for removal of waste from the collection pit. Design requirements of storage facilities that will aid in reducing odors will be evaluated. Inside and outside storage facilities will be used. Measurements will be made of humidity, moisture content, age of manure, temperature of drying, temperature of storage, and time of storage. Evaluation of storage effectiveness will be based on odors, microorganism growth--such as molds--and NH(3) and CO(2) production. Research will be conducted in the laboratory and in the field.

PROGRESS:

SUPPORTED BY U.S. Dept. of Agriculture

3.0237, DISPOSAL AND UTILIZATION OF DAIRY AND POULTRY MANURES BY LAND APPLICATION

D.C. LUDINGTON, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00333)

OBJECTIVE: Develop and evaluate disposal and utilization systems for land application of treated and untreated dairy and poultry manure that will minimize the pollution of water, soil, and air.

APPROACH: Develop and evaluate process systems for handling and treating dairy and poultry manures for application to the land. Properties essential to the design and evaluation of the systems will be measured and integrated into the analysis of the system. Biological, thermal, and physical processes will be studied. The system will be evaluated on the ability to minimize air pollution during storage and land application and water pollution after application.

PROGRESS: Chambers containing 4 liters were aerated at rates of 3, 2, 1 and 0 cfh. A detention time of 40 days was employed and the temperature was 16 C. The following analyses were made on the samples withdrawn: total and ortho phosphate, total Kjeldhal and ammonia nitrogen, COD, pH, alkalinity, total and volatile solids and olfactory threshold. The ash was analyzed for Ca, Mg, K and Na. The air leaving the chambers was analyzed for NH(3), CO(2), odor presence and offensiveness. The pH of aerated systems is relatively high (8.5-8.7) thus increasing the amount of nitrogen loss in the form of NH(3). At the end of 70 days the loss of total nitrogen in chamber one was 37%, in chamber two 35%, 19% in chamber three and 3% in chamber four. The odor offensiveness of the chambers at 40 days were 3.0, 4.2, 6.0 and 8.2 (increasing number indicates increasing offensiveness). Large quantities of nitrogen can be removed from

poultry manure during aerated storage. This loss will not increase the CrN ratio enough to make the manure optimum for soil microflora assimilation. By adding lime to the slurry and raising pH, significantly greater quantities of nitrogen can be removed. The offensiveness of the waste was considerably reduced by low rate aeration.

SUPPORTED BY U.S. Dept. of Agriculture

3.0238, SANITARY MILK PRODUCTION
R.P. MARCH, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00666)

OBJECTIVE: Study the factors of importance in sanitary production and handling of milk on farms. Methods for measuring sediment and problems in sample collection and storage will be investigated.

APPROACH: Procedures and chemicals will be evaluated and special attention will be given to the determination of heat loss during cleaning in relation to methods and materials available. Testing and evaluation of pumps, releasers, filters and other items will be conducted in the interest of making better equipment available to farm and milk plant operators. Research on the causes and prevention of off- flavors will continue and field surveys of milk flavor quality will be made. Cooperation with Departments of Agricultural Engineering and Animal Husbandry and the College of Veterinary Medicine in the milk machine project will continue.

PROGRESS: Waste disposal - A field study of milking center waste disposal systems and their relationship to milk sanitation has been continued to point out the need for more research and extension help in this area. Universal sample - A new system of collecting farm bulk tank milk is being field tested. This is a universal sample which would simplify the sampling system for the bulk hauler and for the laboratory. Fresh vs. composite samples - Preliminary studies indicate that testing fresh samples for fat content four times per month could replace the need for collecting a daily composite sample. Sediment testing - Preliminary studies indicate that a 6 oz. sample of milk can be used to determine the sediment content of milk in lieu of a 16 oz. sample.

SUPPORTED BY New York State Government - Albany

3.0239, POULTRY WASTE MANAGEMENT AND ODOR CONTROL
C.E. OSTRANDER, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00892)

OBJECTIVE: Develop better methods of handling, storing and use of poultry waste products and to eliminate odors emitted from these.

APPROACH: Studies will be made at our research farm and in the field of methods of handling, storing and using or disposing of poultry wastes. Solids, pH, effects of chemical application on the product will be sampled and studied. Effects of temperature, relative humidity and atmospheric pressure on odors emitted will also be studied.

PROGRESS: Screening and testing of chemicals for the suppression and prevention of odors from poultry manure from poultry houses has been continued, some 10 additional chemicals have been tested in the laboratory. None of the chemicals tested showed sufficient promise to be tested in our environmental chambers at our research farm, or were they tested at commercial poultry farms. AK-Tiv-X and Atlas G-271 when tested in liquid poultry manure produced some change in odor, but the odor was still rated objectionable by odor panelists. Methogen (Paraformaldehyde) was tested in fresh liquid poultry manure for the prevention of odor, and in 42 day-old liquid poultry manure for the suppression of odor over a 30-day period. Neither of these tests showed favorable results. There was a definite lowering of PH noted in the 30- day test. Odor panelists reported a change in the odor, but a majority strongly objected to the resulting odor.

SUPPORTED BY New York State Government - Albany

3.0240, POULTRY MANURE PROPERTIES, HANDLING AND DISPOSAL
A.T. SOBEL, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00042)

OBJECTIVE: Determine chemical, physical and rheological properties of poultry manure related to handling, disposal, and/or utilization; investigate several methods of disposal and utilization.

APPROACH: Properties related to handling, disposal or utilization of manure will be determined. Samples will be gathered from various sources to obtain a broad range of breed, management, and other factors which will influence the composition and quantity of manure produced. Such conditions will be recorded so that ranges can be established for various properties, as extremes of these ranges are important in handling manure. Manure will be investigated as a solid waste and as a suspension in water. This information will then be used in trial methods in laboratory (or in the field if indicated) and results extended to consider what would be involved in handling larger quantities of manure.

PROGRESS: Studies were continued on the factors which affect moisture removal from chicken manure. Studies on the effect of air velocity on drying time were initiated. No results are available. Techniques for measuring odors and gases were applied to various manure collection systems on a laboratory and semi-field scale basis. Chicken manure stored in a diluted state produces considerably more H(2)S than when stored in an undiluted state but release of the H(2)S is only about twice as fast. Diluted manure also produces more NH(3) but the undiluted manure releases more NH(3). The relationship between the production and release of these gases is due to their solubility in water and pH. During quiescent storage, the strength of the odors released is comparable for both systems but vastly different in quality. Manure collected in a low moisture state about 25 percent, wet basis had a minimum odor rating. Also there was substantial weight and volume reduction for the dry collection. Preliminary investigations have been initiated on enhancing drying under caged laying hens by various means of mechanical devices.

SUPPORTED BY U.S. Dept. of Agriculture

3.0241, POULTRY MANURE DISPOSAL AND ASSOCIATED ODOR CONTROL
A.T. SOBEL, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (901-031-B609)

OBJECTIVE: Make an engineering feasibility and cost analysis of elements deemed to have most promise of successful incorporation into commercial enterprises.

APPROACH: Study manure management, handling and disposal methods and equipment (including experimental) currently in use in New York State poultry enterprises. Analyze and evaluate selected component features and elements showing promise of productive adaptation. Report analysis of probable results of combining equipment and methods into systems recommended for further study under experimental conditions.

PROGRESS: A study of methods for removal of water from poultry manure shows the equilibrium moisture content at 70 F. to be 19% w.b. at 90% RH and 9% w.b. at 10% RH. Typical drying times to equilibrium under static conditions were 45 hours at 35% RH and 70 hours at 56% RH both at 80 F. Variation of the manure within the samples has more effect on drying than does humidity variation within a (over -) 15% range of RH. The loss of water from a manure surface is less than that from a free water surface and in a batch sample of manure the loss decreases with time. The moisture loss from the batch sample of manure occurred in the top 1/4-inch of depth. Reducing the thickness of the manure sample had a significant effect on the drying characteristics.

3.0242, IMPROVEMENT OF TREATMENT OF FOOD INDUSTRY WASTE
S.B. TUWINER, R A I Research Corporation, *Long Island City, New York* 11101

3. SOLID WASTE MANAGEMENT

To investigate on a laboratory scale electrochemical oxidation of milk whey as a method of waste treatment.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

3.0243, IMPROVED CAPABILITIES OF BIOLOGICAL SYSTEMS TO ASSIMILATE OIL
R.N. SIMONSEN, Amer. Petroleum Institute, *New York, New York* 10020

The project will consist of a study of laboratory scale activated sludge waste treatment systems which will be operated to determine their tolerance to various types and amounts of hydrocarbons, the nature of the interference of the hydrocarbons, the fate of the hydrocarbons in the system, and to study methods for improving pretreatment of the influent and of improving the operation of the systems.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

3.0244, SEPARATION OF SANITARY SEWAGE FROM COMBINED SYSTEMS OF SEWERAGE
M.B. MCPHERSON, Amer. Soc. of Civil Engrs., *New York, New York* 10017

The general concept on which the project is based involves discharging comminuted or ground sewage from individual buildings and/or building complexes through relatively small pressure tubing laid in existing building connections, and thence into new pressure conduits suspended in existing street sewers. The new separate sanitary sewage pressure conduits would then discharge into existing interceptors that would convey the sanitary sewage to treatment works. Storm water alone would be carried in what were formerly combined sewers. The most comparable alternative to meet the same objective is traditional, complete separation by means of new sanitary sewers and attendant separate sanitary and drainage building connections. The project scheme was conceived by Dr. Gordon H. Fair of Harvard University.

The basic objectives of the project are to determine the physical feasibility and limitations of the project scheme or modifications thereto, and to arrive at measures of cost for comparison with the traditional method of separation for evaluation of investment feasibility.

Headquarters for the project are provided by Harvard University at 40 Oxford Street, Cambridge, Mass. 02138.

3.0245, HYDROLYSIS OF SLUDGE USING LOW PRESSURE STEAM WITH SO2 AS A HYDROLYTIC ADJUNCT AND TO STUDY THE UTILIZATION OF THE RESULTING HYDROLYSATE
B.C. REIDY, Foster D. Snell Incorporated, *New York, New York* 10011

To conduct a feasibility study to determine the effectiveness of a chemical process utilizing dilute sulfurous acid to digest and hydrolyze sludges of various types produced in waste disposal processes.

An evaluation of the economic aspects of the process will be made once the best reaction conditions are determined. This evaluation will include factors affecting the desirability of incorporating this process as an alternate disposal system. These include: (1) Chemical composition of digested products and the solid residue. (2) Process and equipment costs which are a function of temperature, pressure, and chemical composition. (3) Raw materials costs, such as SO2. (4) A study of methods of ultimate disposal of the undigested (inorganic), portion of the sludge and its potential use as fertilizer or soil conditioner, etc. (5) A study of the utilization of the concentrated digest as a fermentation adjunct, cattle feed (digest molasses), etc.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0246, URBAN SCIENCE AND ENGINEERING
R. NATHANS, State University of New York, School of Arts, *Stony Brook, New York* 11790

In collaboration with the Rand Institute of New York City and with the cooperation of public agencies in Nassau and Suffolk Counties, the Urban Systems Engineering group will conduct interdisciplinary research on flow of solid wastes and on fire protection.

Data obtained from existing literature and a case study of the sources and disposal of solid wastes will be used to construct a benefit-cost model of the waste-disposal system.

Building on the experience of the Rand Institute with research on fire protection, operations analysis will be concerned with problems of fire protection in an area characterized by rapid urbanization. Computer simulations will be used to develop estimates of benefits and costs associated with alternative systems.

The aims are to determine the analytical investigations that are likely to be of immediate benefit to public agencies, to develop a close working rlationship with the Rand Institute, to strengthen the interdisciplinary research resources of the Urban Systems Engineering group, and to construct a series of models describing the essential features of selected urban systems. The research will be closely tied to a graduate program involving students in engineering, economics and physical sciences.

SUPPORTED BY U.S. National Science Foundation

3.0247, PIPELINE FLOW OF SOLIDS-LIQUID SUSPENSIONS
R.M. TURIAN, Syracuse University, Research Institute, *Syracuse, New York* 13210

The primary objective of the proposed research is to assess the effect of suspending medium characteristics and suspended solids properties on: 1. the steady state pipe flow behavior of the suspension, 2. pressure lossess and other problems associated with the flow through pipe bends or other disturbances in the flow path, and 3. problems arising from sudden stoppage and subsequent start-up of the flow. The suspending medium characteristics will be varied using Newtonian liquids of different viscosities and densities, suspensions of solids fines of different concentrations and polymer average molecular weight. The suspended solids characteristics, on the other hand, will be varied using different concentrations of iso-dimensional particles, different solids densities, and different distributions of particle sizes and densities. Supplementary viscometric, settling, and other tests will be conducted to characterize the suspended systems investigated and their components. These supplementary tests will also serve to evaluate the utility and limitations of such measurements in the prediction of the pipe flow behavior of the suspension. The ultimate aim is to establish guidelines for optimum design and economic evaluation of a sludge or suspended waste pipeline or piping system.

3.0248, INCINERATION OF PLASTICS FOUND IN MUNICIPAL REFUSE
R.W. HEIMBURG, Syracuse University Res. Corp., *Syracuse, New York*

A systematic study of the destruction of synthetic polymers, especially plastics and plastic-rich refuse by two incineration methods will be performed. The two methods are (1) direct burning of the refuse, and (2) anaerobic heating followed by burning of the volatile matter. Of particular interest are (1) the chemical and toxicological nature of the stack effluent and (2) the interaction of the solid residue with water. We are ultimately interested in finding a process and/or set of incineration conditions which results in the destruction of plastics-rich refuse with minimum air and water pollution.

3.0249, JOINT LAND-USE FOR CONSERVATION OF NATURAL RESOURCES AND DISPOSAL OF SOLID WASTES
H.I. STERN, Rensselaer Polytechnic Inst., School of Engineering, *Troy, New York* 12181

The rapid growth of urban-suburban regions creates a demand for new construction materials such as sand and gravel, while simultaneously encroaching upon the land used for mining such mineral aggregates. Urban growth also results in the increased generation of solid waste and the resulting search for suitable land fill sites. Since the mineral aggregate production and delivery operation is spacially complementary to the solid waste transportation and disposal activity, the optimal manner of doing both operations will be investigated. For multi-site joint operations a special problem of dual purpose truck assignments and scheduling of deliveries is to be studied. The problem must be coupled with the sequencing of opening and closing times for mineral sites which reflect resource conservation policies.

SUPPORTED BY U.S. National Science Foundation

3.0250, OXYGEN TRANSFER IN CONCENTRATED MICROBIAL SYSTEMS
D.R. WASHINGTON, Rensselaer Polytechnic Inst., School of Engineering, *Troy, New York* 12181

This project has at its immediate aim, the development of mathematical models to express the oxygen transfer, oxygen utilization for concentrated mixed microbial cultures. A major effort is being made to evaluate the coefficients appropriate for the models. The investigation involves the study of cultures ranging from 15 gm/l to 50 gm/l suspended volatile solids.

The long range objective of the research is to develop a biological process for the direct treatment of concentrated industrial wastes which are susceptible to biological degradation. Synthetic wastes (45% dextrose; 45% non-fat milk, 10% yeast extract) in concentrations up to 30 gm/l COD have been treated by this process with over 99% COD removal.

3.0251, MICROBIOLOGY OF ANAEROBIC SLUDGE
R.A. MAH, Univ. of North Carolina, School of Public Health, *Chapel Hill, North Carolina* 27514

An ecological apparaisal of the sludge fermentation is essential to an understanding of the contribution and significance of various physiological types of anaerobic bacteria participating in the degradation or organic compounds to methane and carbon dioxide. This investigation is concerned with an estimation of the total fermentation by whole sludge of certain carbohydrates, fatty acids, and amino acids. The significance of the bacteria which attack these compounds will be evaluated by isolation of pure cultures, estimation of their numbers in sludge, and determinations of their rates of fermentation of specific substrates.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0252, ANIMAL WASTE COMPOSTING WITH CARBONACEOUS MATERIAL
C.B. DAVEY, Univ. of North Carolina, School of Agriculture, *Raleigh, North Carolina* 27607

Poultry manure has been mixed with sawdust and composted in a high rate thermophilic composter. The temperature increases to 60 to 70 degrees C within 24 hours and remains at this level for another 24 hours before decreasing. During this period, the available carbon is supplied by the manure. Nitrogen loses were found to be approximately 3 percent. After being removed from the composter, the material is stored. During storage the cation exchange capacity of the compost increases to about 67 milliequivalents per gram. The odor becomes that of fresh soil.

Plant growth studies in green houses using compost at least four weeks old were made. Tomatoes planted in a mixture of soil and 10 percent compost by weight exhibited an increase in dry weight of 400 percent over untreated plants after 90 days. The tomato yield was also greatest at this treatment. Wheat and millet also exhibited the greatest dry weight increase at this treatment. Green beans had their greatest dry weight increase at the one percent level. Seed production and root nodule growth was also greatest at this level.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0253, PHYSICAL AND CHEMICAL CHARACTERISTICS AND STABILITY OF CUCUMBER PRODUCTS
J.L. ETCHELLS, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC05109)

OBJECTIVE: Conduct chemical, microbiological and technological research relating to the preservation, curing and storage of cucumber pickles and to the properties of raw and processed products.

APPROACH: Investigations will be made of the effects of alternative raw product handling techniques upon microbiological, physical and chemical properties of the raw product over time and upon the processing characteristics of the product. Alternative means of controlling the microbial population so as to obtain controlled fermentation will be investigated.

PROGRESS: Brining with a 'Salt-Free' Brine: The ever mounting problems attending waste disposal from the brining and manufacturing operations of the brined vegetable industry have directed our curiosity to the possibility of fermenting cucumbers in a SALT-FREE brine (meaning, of course, free of sodium chloride). Six common organic salts, including sodium chloride (potassium chloride, ammonium nitrate, potassium chloride, ammonium nitrate, potassium nitrate, magnesium sulfate, and ammonium sulfate) were tested at three concentrations (3, 6 and 9%) in cucumber-juice broth for their ability to support growth of various species of lactic acid bacteria and yeasts. All the test organisms grew almost equally as well in all the six salts at the 3% concentration; higher concentrations showed the most inhibitory effect on the gas-forming species of lactic acid bacteria. The brine yeasts grew well in all six salts at all three concentrations. Brining tests in 1-gallon jars supported the findings just mentioned. The results demonstrated that in general, the cucumbers brined with the five different inorganic salts produced vigorous acid fermentations. Further information will be gained when the brine-stock from all lots is evaluated.

SUPPORTED BY North Carolina State Government - Raleigh

3.0254, PULP INDUSTRY POLLUTION ABATEMENT THROUGH PROCESS MODIFICATION
P.J. KLEPPE, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC04025)

OBJECTIVE: Study the possibility of converting the reducing sulphur components in the kraft pulping process to non-polluting substances by oxidation with oxygen before blowing, and of replacing the chlorination and alkali extraction stages in bleaching with one oxygen/caustic stage.

APPROACH: From a study of pulping kinetics optimum conditions will be determined for oxidation of sulphur compounds in the pulp digester and laboratory trials undertaken. Studies on bleaching kinetics will also be undertaken to determine the feasibility of utilizing a one stage oxidation-caustic process. Laboratory evaluation of the resultant pulps shall be also undertaken.

PROGRESS: About 80% of the lignin in a Kraft pulp containing 10.5% lignin could be removed in 80 minutes at 100 C by oxygen and alkali. The gain in brightness was about 25-30 G.E. units and the ratio of lignin to carbohydrate removed was considerably higher than for Kraft pulping. The alkali consumption was less than 10% NaOH and the consumption of oxygen was only about 3% (based on pulp). The results indicate strongly that removal of lignin from high yield pulps by oxygen and alkali can be a feasible and economical process, and can replace the chlorination and 1st alkali extraction stages in bleaching of pulps. An inplant study was also made on materials balance in white water recirculation during paper maker. An M.S. thesis on the latter study is in preparation.

3.0255, SURVEY OF PULP AND PAPER MILL EFFLUENT CONTROL AND TREATMENT
C.N. ROGERS, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC04017)

3. SOLID WASTE MANAGEMENT

OBJECTIVE: Survey and evaluate methods of effluent improvement for paper mills in the south.

APPROACH: Survey industrial operations by questionnaire and direct contact. Evaluate and analyze findings to identify problems. Prepare report.

PROGRESS: During 1968 questionnaires were sent to about 60 of the major pulp and paper producers in the South who had previously shown interest in our project. These companies represent about 90% of the tonnage produced in the South. Forty-five of these questionnaires have been completed and returned, and the remainder are expected within the next few months. These questionnaires, which were extensive in coverage and tailored to fit our interest, were filled in as completely as possible by nearly all of the mills. Many of the mills installed facilities to provide the information which we requested. It should be pointed out that almost all of the mills provided us with all technical and cost data available to them. Many managers have stated that the questionnaire has been helpful to them, as it has pointed out information that they should know about their own operations for improved results. During the past year about 10 of the mills have been visited to get additional information and to verify some that was given previously. We propose to visit an additional ten mills which will give 1/3 coverage of those participating. We are currently using information provided by this project in a program of teaching pollution abatement as well as in other research projects.

SUPPORTED BY U.S. Dept. of Agriculture

3.0256, FARM ANIMAL WASTE DISPOSAL

G.L. PRATT, North Dakota State University, Agricultural Experiment Sta., *Fargo, North Dakota* 58103 (ND-H-04-013)

OBJECTIVE: Characterization of physical, chemical and biological properties of livestock and poultry wastes, improvement in management systems with regard to handling treatment and disposition of wastes.

Approach: An evaluation survey will be made of farms in North Dakota using liquid manure handling systems for hogs and poultry. The lagoon system of sewage disposal receiving liquid manure from a hog house will be studied in detail including temperature, odor, B.O.D., etc. Open pit septic tanks will also be studied.

Progress: A lagoon is being used for disposal of hog wastes. The system was modified by adding a settling tank between the barn and lagoon. A high pressure water system was installed to clean the barn. The effectiveness of the removal of solids from the wastes by the settling tank will be evaluated. Three reinforced concrete grids are being evaluated to determine design criteria for floor systems for cattle and hogs. A cage laying system was installed at the poultry plant with a gutter system designed to be cleaned with wash water. Water is salvaged from the wastes to be reused for washing the gutters under the cages. Odor from the reused water is a problem. The Bacteriology Department has worked on the identification and enumeration of the microbial flora of the Nutrition Center Sewage lagoon. The pigmented organisms appear to belong to the bacterial families Thiorhodaceae (probably Thiopedia rosea) and Athiorhodaceae. Assay of influent and lagoon waters are underway to determine the concentration of biochemically important nutrients and metabolic byproducts. No practical applications have been made.

SUPPORTED BY U.S. Dept. of Agriculture

3.0257, LIVESTOCK WASTE DISPOSAL SYSTEM INVOLVING REUSE OF WATER

G.L. PRATT, North Dakota State University, Agricultural Experiment Sta., *Fargo, North Dakota* 58103 (ND-S-04-010)

OBJECTIVE: Compare and evaluate on the basis of available information the components needed to condition animal waste water for reuse, assemble pilot treatment systems to evaluate performance of components in field use.

APPROACH: Initial phase will involve a review of components that are available for separating solids from liquid, for eliminating undesirable chemical elements, and for neutralizing pathogens. Commercially available components will be investigated. Available information on quantity of materials that will have to be handled will be summarized. Evaluation of mechanical performance of selected systems will be made in a pilot disposal assembly. Waste material will be collected from livestock and introduced into test systems. Rate of buildup of undesirable chemical elements in reused water will be determined. After these rates have been established, efficiencies of equipment available for removing these chemical elements will be evaluated. Determination of efficiencies of pathogen neutralizing equipment will be the final stage of pilot test sequence.

PROGRESS: In one phase of the work treatment of overflow from settling tank that collected beef waste was emphasized. No treatment, aeration, and treatment with aluminum sulfate (alum) were tested for settling tank overflow. The settling tank removed the bulk of solids. Alum treatment of the overflow was effective in reducing total solids to the point where it was nearly feasible to provide final treatment. In the second phase of the work a slow sand filter was tested under controlled conditions to determine its adaptability for final treatment of reclaimed water. Tests were run at three temperatures, 45 F, 70 F, and 100 F. Controlled amounts of organic material were added to the influent of the filter. The filter was easily managed and adaptable to a wide range of conditions. Its performance was better at 70 F than at 45 F or 100 F.

SUPPORTED BY North Dakota State Government

3.0258, WASTE TREATMENT FACILITIES DEMONSTRATION

C.R. MOORE, Union Stockyards Company, *Fargo, North Dakota* 58078

The project will consist of a pilot study and demonstration of the Union Stockyards Company of West Fargo, North Dakota waste materials. A study shall be made of the effluent leaving the pens and wash rack of the Stockyards Company from April 1, 1970 until the treatment facilities are constructed.

Treatment facilities consisting of a screen for removing solids, a sewage lift station, and primary and secondary waste stablization ponds shall be constructed. During the summer of 1970 when this construction is taking place, samples of the effluent shall be taken and tested periodically.

After construction of the treatment facilities, the effluent from the screen and waste stablization ponds shall be sampled and tested until Sept. of 1971. After this time a written report and evaluation shall be prepared on the results.

At the present time there are 48 sales and feed lots in North Dakota which have no treatment facilities, there are 50 in South Dakota and nearly as many in Northern Minnesota. From the pilot study made with this project it is proposed that we can demonstrate a practical and economical method of treating the wastes from these other feed lots and stockyards.

Since most of the operators of feed lots and sales lots visit the Union Stockyards in West Fargo periodically it would be an ideal place for these people to observe the operation of the treatment facilities.

It is felt that through the construction of the facilities proposed we will be able to sufficiently reduce the suspended solids and reduce the B.O.D. to acceptable limits for discharge into the Sheyenne and Red Rivers.

The project will be started June 1970 and completed in December 1970.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0259, ULTIMATE DISPOSAL OF SLUDGES BY SURFACE SPREADING

J.O. EVANS, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

Land surface provides low cost dewatering and oxidation of organic sludges with additional benefits from added soil fertility. Certain insoluble mineral wastes such as calcium carbonate and phosphate are compatible with many soils and can also act as fertilizers. Since dewatering of sludges by sedimentation, centrifugation, or filtration is expensive, a study of wet sludge disposal on land surfaces has been initiated. Pipeline transport of sludges and stabilization to prevent nuisance odors will be studied. Distribution programs to minimize pollution from runoff and percolation will be devised. Long term effects of repeated sludge applications to various soil types will be evaluated.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0260, SUSPENDED AND COLLOIDAL SOLIDS REMOVAL--FLOCCULATION BY ORGANIC POLYMERS
S.A. HANNAH, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

The need for solids-liquid separation arises at a number of steps in the treatment of wastewater either by chemical or biologic processes. The newly developing organic flocculants represent the best currently available group of chemicals to 1) increase efficiency of solids-liquid separation, 2) minimize sludge mass and 3) improve thickening and filtration properties of sludge.

The overall objectives of this study are to 1) investigate the application of new organic flocculants in waste treatment, 2) determine the mechanism of the flocculation by organic polymers and 3) develop methods for the control of dosage to obtain economic use of these relatively expensive compounds.

A wide variety of polymer compounds distinguished as to chemical composition, charge type, charge density and molecular weight will be studied. The polymers will be studied both alone and in conjunction with inorganic hydrolyzing chemicals such as aluminum or iron salts. Variables to be evaluated include polymers, dosages pH, ionic and solids characteristics of wastewater before and after treatment, effects of agitation and mode of addition of polymer. Experimental apparatus and instrumentation used in the study will include: jar test apparatus, miniature sand filters, microelectrophoretic techniques, colloid titration, and streaming current measurement devices.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0261, SUSPENDED AND COLLOIDAL SOLIDS REMOVAL--SOLIDS SEPARATION BY CHEMICAL TREATMENT AND FILTRATION
J.F. KREISSL, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

The separation of suspended solids, either those existing or created by chemical and biological treatment, from waste effluents is a recurring step in the series of processes for advanced methods of treating wastewaters. Plain sedimentation followed by surface or depth filtration have proved to be insufficient for the production of the high quality of effluents required for membrane or adsorption processes. Chemical treatment to obtain coagultion and flocculation followed by filtration appears to be the most promising approach for the complete clarification of wastewaters.

The overall objectives of this investigation is to develop a clarification process which will encompass the following 1) coagulation- flocculation in an upflow-solids contact clarifier, 2) filtration using depth filters such as sand, sand and coal or other media combinations.

The experimental apparatus will consist of a series of specially designed columns, approximately 1 foot square, in which the functions of coagulation-flocculation and rough sedimentation can be accomplished. Effluent from these treatment devices will be filtered in a variety of filter media columns. Some of the experimental variables will include 1) upflow velocity, sludge blanket depth, type of coagulant, coagulant dosage, mixing conditions, time of coagulation or flocculation, filter media and rate, etc. Performance of the process will be assessed by measuring such parameters as turbidity, coagulant ion, head loss, etc.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0262, TREATMENT OF BEAN HOUSE WASTES FROM A VEGETABLE TANNERY
J.D. EYE, Univ. of Cincinnati, School of Engineering, *Cincinnati, Ohio* 45221

The objectives of the project are to demonstrate the feasibility of treating bean house wastes from a tannery and to obtain basic data for the design of full scale treatment plants. Excess lime from the lime bearing wastes will be removed with polyelectrolytes. The clarified lime wastes will be mixed with non-lime bearing wastes and neutralized with acid to a pH of 8.5 - 9.0. The organic material in the blended neutralized wastes will be reduced by a combined anaerobic- aerobic biological system.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0263, HEAT TRANSFER STUDIES ON SLUDGE SUSPENSION
UNKNOWN, Rand Development Corporation, *Cleveland, Ohio* 44110

The proposed project is a study of disgested sludge which is to be economically disposed of by transport in small diameter pipelines, and which can beneficially be used in land surface reclamation.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0264, FIRESIDE METAL WASTAGE IN MUNICIPAL INCINERATORS
P.D. MILLER, Battelle Memorial Institute, *Columbus, Ohio* 43201

The objectives of the work planned are to identify the conditions that lead to the corrosion of metals in solid-waste incinerators, to determine the mechanisms by which the loss occurs, and to devise means of preventing corrosion in these installations.

Field studies will be carried out by continuing the practice of inserting probes in operating municipal incinerators. Corrosion rates will be determined my measuring the weight loss of specimens held at selected temperatures. Analyses of the deposits, and of the corroded metal will help strengthen the conclusions which have already been reached as to the cause of the attack.

Possible mechanisms by which the corrosion is occurring will be established by laboratory studies. The role of individual corrosive constituents will be determined. Reasonable explanations for attack at 800 F and 1000 F have already been obtained, but additional studies are required to explain results at temperatures of 600 F and lower.

Particular emphasis in this year's effort will be directed toward developing practical procedures for the alleviation of the metal wastage. Field studies will include evaluations of both a variety of alloy compositions and of protective coatings applied to plain carbon steels. Consideration will be given to the most effective design or operating conditions which will reduce metal wastage.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0265, RENOVATION, UTILIZATION OR SAFE DISPOSAL OF EFFLUENT FROM SEPTIC TANKS AND SEWAGE PLANTS
B.L. BONDURANT, Ohio State University, Agricultural Experiment Sta., *Columbus, Ohio* 43210 (OHO00346)

OBJECTIVE: Study and develop methods for renovating sewage treatment effluents. Determine possible and practical uses of sewage treatment effluents and renovated effluents as related to agricultural production and rural water supplies.

APPROACH: Soil will be used as a medium for renovating sewage treatment wastes with emphasis on maintaining aerobic conditions within the soil, the effluent and at the interfaces through proper loading, drainage, transpiration and evaporation balances. Lysimeter columns will be used in the laboratory, sites where unsatisfactory septic tank performance occurs will be studied later. Observations of phosphates, nitrates, pH and permeability will be made where growers are using treatment plant effluents. Septic tank effluent will be tried for lawn irrigation, flushing toilets, etc.

PROGRESS: Soil lysimeters 19 inches in diameter and 6 feet high were obtained from one soil for purposes of conducting leaching studies. Installation is in progress. Several contacts were made with owners of existing septic systems regarding modification of their systems to permit reuse of the water. A milkhouse waste disposal system was partially installed, but no data have yet been collected.

3. SOLID WASTE MANAGEMENT

SUPPORTED BY U.S. Dept. of Agriculture

3.0266, FARM ANIMAL WASTE DISPOSAL

E.P. TAIGANIDES, Ohio State University, Agricultural Experiment Sta., *Columbus, Ohio* 43210 (OHO00413-S)

OBJECTIVE: Determine physical, chemical and biological properties of animal wastes. Evaluate various systems of farm waste management. Test under experimental conditions, one or more promising systems in waste handling treatment and disposal.

APPROACH: Facilities at Wooster and Columbus will be used to collect data on the daily defecation rates of dairy cattle, beef cattle, swine, poultry and sheep. Samples will be analyzed for total and volatile solids, specific gravity, BOD, COD, C, N, P, K, B, Ca, Mg, Zn, etc., and correlated with feed, animal and production parameters. New systems utilizing processes used in industrial waste processing will be studied. Processes to be considered for investigation are field spreading of liquid manure, decomposition at low temperatures, incineration, aeration, algae production, coprophagy, sterilization drying at high temperature, etc.

PROGRESS: In the determination of the oxygen demand parameters of animal wastes, seeding, temperature, method of determination, and type of waste have a significant effect. Storage of samples at below 2 C, dilution do not have a significant effect. The quantities of the total excrement from animals is significantly affected by the feed, the weight of the animal, and the type of the animal.

SUPPORTED BY Ohio State Government

3.0267, CONVERSION OF EXISTING ANAEROBIC DIGESTERS TO AEROBIC DIGESTERS - FULL PLANT SCALE

H.W. AUGENSTEIN, Hamilton City Government, *Hamilton, Ohio*

Hamilton, Ohio, is a city of about 75,000 people located on the Great Miami River in Southwestern Ohio. This city has a modern, split- treatment activated sludge sewage plant designed for 12 MGD primary treatment and 6 MGD secondary treatment. Separate sludge digestion and vacuum filtration are included. The wastewater received is somewhat atypical because of a one million gallon daily contribution by a local paper industry. This waste contributes a high percentage of the raw sewage solids and appears to be partly responsible for continuous difficulty with anaerobic digestion.

The research project involves the conversion of two existing floating cover digesters (80 ft. diameter, 15 ft. sidewall) aerobic units. After conversion, the covers will rest on the ledge and will be properly vented. The installation will include three 300 cfm blowers equipped with ammeter type flow indicators. Diffusion will be by a 96 inch diameter eductor tube in each digester.

One converted digester will be operated on a carefully controlled program of varied sludge volumes, aeration rates and temperatures using a mixture of raw primary and waste activated sludge. The other unit will take the excess sludge.

Vacuum filtration of the aerobically digested sludge will also be examined.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

3.0268, ENGINEERING SYNTHESIS OF EFFICIENT, ECONOMICAL DAIRY PRODUCTION SYSTEMS

W.L. ROLLER, Ohio Agric. Res. & Dev. Center, *Wooster, Ohio* 44691 (OHO00347)

OBJECTIVE: Improve the efficiency of milk production systems by the application of engineering principles to the equipment, processes and controls needed for dairy mechanization.

APPROACH: Review technical literature pertaining to dairy mechanization and synthesize several possible production systems on paper for study. Locate areas where reasonably small advances in technology may improve the total system efficiency and work on these developments. Begin the development of research approaches for solving major problems existing in dairy farm mechanization. As research approaches become apparent, projects will be outlined and submitted for support to carry out the research.

PROGRESS: This past year work was completed on system equations to compute expected returns from milk production systems and equations were incorporated into a computer program. Milk production systems using different types of housing, milking parlors, manure handling facilities and feeding systems were analyzed by use of work routines, cost budgets and expected-returns equations. Systems at different levels of milk production, cow life, and system life were compared. New layouts of the system called free stanchion housing (FSH) were drawn and ventilation requirements calculated. FSH was found to have less investment and labor requirements than best existing enclosed free stall system for herd sizes above 100 cows due to a redesigned feed manger layout. New areas of research needed to improve milk production systems include field testing of FSH, freezing of chopped hay, and mechanical removal of the milking claw. An automated calf feeder capable of feeding calves predetermined amounts of milk or milk replacer at specific times of the day, using a pipeline feed distribution system, was developed and tested for reliability. Improvements were made in the mixing chamber so that recirculation of liquid is used to achieve mixing of milk replacer. Calf performance testing was started.

SUPPORTED BY U.S. Dept. of Agriculture

3.0269, PHOSPHATE REMOVAL BY ACTIVATED SLUDGE PROCESS APPLICATION - PLANT SCALE DEMONSTRATION

L.D. LIVELY, U.S. Dept. of the Interior, Federal Water Quality Admin., *Ada, Oklahoma* 74820

Objective - The positive confirmation of an imposed biological phosphorus removal on a sustained basis at a plant which had a prior record of limited removal of phosphorus.

Locate and study activated sludge sewage treatment plants which meet critical design criterion pertinent to biological phosphate removal. The plants are to be located in different geographical regions of the Continental U.S.A. Chemical and operational characteristics will be determined to ascertain what changes are necessary for such plants to serve as demonstration plants for the biological phosphate removal process.

Description - 1. Negotiate, establish, and monitor plant scale research demonstration for five municipalities to be operated for one full year. 2. Establish system to monitor three additional sewage treatment plants known to be removing phosphorus by the activated sludge process at the present time. 3. Conduct survey and amenability studies on four more activated sludge plants in the Northeast, Southeast, Northwest, and Southwest Regions of the FWPCA to complete scope of phosphate removal project in selecting plants and identifying parameters critical to mechanism, kinetics, operation, and sustenance of the process.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0270, PHOSPHATE REMOVAL BY ACTIVATED SLUDGE PROCESS SPECIFICATION - PLANT SCALE RESEARCH

F.M. PFEFFER, U.S. Dept. of the Interior, Federal Water Quality Admin., *Ada, Oklahoma* 74820

Objective: The verification and quantification of the specific design and operational parameters which control phosphorous removal in activated sludge plants.

Description: Conduct one-year plant scale research program to meet objectives at a city of choice, known to be removing phosphate on a plant scale.

Define range and limits of operation and design parameters of phosphate removal process.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0271, RESEARCH INITIATION-PHYSIOLOGICAL AND STRUCTURAL STUDIES OF SPHAEROTILUS NATANS IN RELATION TO THE BULKING OF ACTIVATED SLUDGE

J.M. ROBERTSON, Univ. of Oklahoma, Graduate School, *Norman, Oklahoma* 73069

The role of Sphaerotilue natans in the bulking of activated sludge will be investigated with particular emphasis on conditions and mechanisms which lead to the bulking situation. Possible chemical binding of sludge materials in a bulked mass by sheath/slime layer or by esterification of the polymer, poly-B-hydroxbutyric acid, will be determined by radiotracer technique, chemical measurements and by direct examination with an electron microscope. Further investigations will be directed toward the elucidation of mechanisms which favor the growth of the highly aerobic S. natans over normal floc-forming organisms at lower oxygen levels. Elucidation of causes of bulking would permit engineers to better design and operate sludge aeration processes.

SUPPORTED BY U.S. National Science Foundation

3.0272, EVALUATION OF BEEF FEEDLOT WASTE MANAGEMENT ALTERNATIVES
A.F. BUTCHBAKER, Okla. St. Univ., Agricultural Experiment Sta., *Stillwater, Oklahoma* 74075

The objectives of this research are: 1. To develop beef feedlot design criteria to minimize pollution from runoff waste and to facilitate handling of solid and liquid animal wastes. 2. To examine alternative feedlot waste disposal to obtain a minimum cost system for effective waste disposal.

The two major segments of the research are the determination of feedlot waste management design criteria and the computer design and analysis of alternative systems. Feedlot design criteria will be determined by examining the literature, observing feedlot operations in major beef producing areas of the Midwest, Southwest, and far West, performing an operational analysis of waste handling operations, and investigating geographical factors that may affect feedlot waste- management systems. Evaluation of alternative waste-management systems for feedlots will be examined by extending a current systems computer program for the evaluation of alternative systems for forage and feedlot operations.

The project begins in June 1970 and ends in February 1971.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0273, CATTLE FEEDLOT PEN DESIGN
A.F. BUTCHBAKER, Okla. St. Univ., Agricultural Experiment Sta., *Stillwater, Oklahoma* 74075 (OKL01208)

OBJECTIVE: Conduct feeding period tests to determine effects of crowding and stress due to space allowance per animal and pen configuration effects in cattle feedlot pens; determine the effectiveness of an oxidation ditch under a slotted floor in beef cattle waste reduction and pollution and fly control.

APPROACH: Crowding and pen configuration stress will be determined by weight gain of two pens of cattle confined to a specified space per animal as compared to gains by a control group, to determine optimum gain vs. cost information for cattle on slotted floors. The control pen will be an outside pen on dirt, comparable with commercial feeding facilities. Waste disposal under the slotted floor will be accomplished by an oxidation ditch, to determine amount of reduction, water needs, power requirements, odor and fly control, and the hydraulic properties of the ditch. Information monitored will include dissolved oxygen, pH, total and volatile solids. BOD, COD, N, K, P, nitrates and nitrites will also be monitored periodically.

PROGRESS: Oxidation ditch studies for cattle waste reduction and pollution control are currently in progress, to obtain design parameters for outside installations in the Southwest. Some foaming and icing has occurred in three weeks of near zero weather but the rotor has continued to perform well. Reduction performance has not been evaluated as activated sludge has not yet been produced. The general objectives initially presented have been met and results published. A revision of the project is to be prepared with primary objectives of investigating the performance of an oxidation ditch for cattle waste reduction and possible lagooning of ditch effluent to minimize pollution potential. No design parameters are currently available for performance of oxidation ditches in open feeding shelters for the Southwest.

SUPPORTED BY Oklahoma State Government

3.0274, RESEARCH INITIATION - REMOVAL OF ORGANICS BY TRICKLING FILTERS
E.E. COOK, Okla. St. Univ., School of Engineering, *Stillwater, Oklahoma* 74074

Trickling filters are artificial beds of stones or porous medium over which an organic waste is applied. Microorganisms present in the organic waste (or supplied from other sources) accumulate on the filter medium and, when they come in contact with the waste and air, remove the organics contained in the waste flow for use as nutrients in biological metabolism. Observation has indicated that the greater the surface area afforded by a particular filter medium on which the microorgainisms can grow and adhere, the greater the ability of the trickling filter to remove the organics contained in the waste stream applied to it.

This research will investigate various trickling filter mediums containing various specific surface areas. The different trickling filter mediums will be compared as to their capability of organic removal per square foot of available surface area, and the relationship of organic removal to available surface area will be determined.

SUPPORTED BY U.S. National Science Foundation

3.0275, BIOLOGICAL CONCEPTS FOR DESIGN AND OPERATION OF THE ACTIVATED SLUDGE PROCESS
A.F. GAUDY, Okla. St. Univ., School of Civil Engineering, *Stillwater, Oklahoma* 74074

During the past nine years, the principal investigators have conducted extensive laboratory research into a variety of aspects of the activated sludge process. These investigations have encompassed kinetic and mechanistic studies of both 'steady' operation and behavior under shock loadings of many types, as well as studies of the mechanisms of metabolic control which operate in heterogeneous populations. The number of man-years which have been devoted to this research is conservatively estimated at seventy-five. All of these studies have been conducted under controlled and comparable conditions. Fifty-eight research papers and publications have emanated from this work to date. However, a large amount of data has not yet been completely analyzed or published.

During the current year the objective is the correlation and conceptual analysis of all of these data, both those previously published and those to be published, leading to preparation of a final treatise on conceptual biological principles governing design and operation of the activated sludge process in terms which can be understood and used by practicing engineers with a wide variety of backgrounds as well as by researchers in the field.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

3.0276, IMPROVED METHODS, EQUIPMENT AND FACILITIES FOR INEDIBLE ANIMAL BY-PRODUCTS RENDERING PLANTS
D.R. HAMMONS, Okla. St. Univ., U.S.D.A. Transp. & Facil. Div., *Stillwater, Oklahoma* 74074 (TF2-101A)

OBJECTIVE: Develop improved layouts, equipment, and methods for increasing efficiency in plant operations; and determine criteria for controlling salmonella contamination in animal by-products rendering plants.

APPROACH: Collection of data concerning both operating efficiency and control of salmonella contamination is nearing completion. These data have been collected from a series of studies of a broad cross- section of small and medium sized rendering plants representing significant variables such as facilities and equipment used, volume produced, handling and processing methods employed, and final products prepared. Data will be analyzed and one or more manuscripts covering the significant findings will be prepared.

PROGRESS: Results of engineering studies in rendering plants indicate that improved layouts, work methods, and equipment can reduce operating costs. These analyses also indicate

that increasing operating efficiency without taking into account the problem of salmonella contamination in rendering plants would not provide the guidelines and assistance needed by this industry. Case studies were completed in six cooperating Oklahoma rendering plants to obtain environmental data for evaluating total bacteria count causes and effects in in-plant operations and product contamination relationships to environmental factors. Some common factors found to be contributing to the high incidence of salmonella in inedible rendering plants are: (1) Excessively long conveyors were used after the cooking process which allowed the product to cool and become recontaminated, (2) uncovered conveyors allowed recontamination of cooked material, (3) crossover conveyors permitted raw material to pass directly over cooked material, (4) poor operating methods allowed product to remain in perc pans too long, (5) almost complete lack of concern by the rendering industry, (6) cross traffic between departments permitted mixing of cooked and raw material, and (7) inadequate grinding of raw material prior to cooking resulted in incomplete kill in the larger pieces.

SUPPORTED BY U.S. Dept. of Agriculture

3.0277, UTILIZATION OF BARK WASTE
H. AFT, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE-F-00861)

OBJECTIVE. Study methods for chemical and physical utilization of bark.

APPROACH. Conduct chemical studies on hemicellulose and lignin of inner bark and develop gas-liquid chromatographic methods for analysis of aliphatic alcohol component of bark extractives and suberin of Douglas fir bark. Determine molding properties of bark with variables of species, particle geometry, moisture content, and chemical additives or extractives prior to molding.

PROGRESS. Two principal lines of research effort were maintained in the physical utilization of bark: (1) pelleting, and (2) molding. Good to excellent pellets of 1/4-and 1/2-inch diameters have been made of several different species of bark and bark mixtures. Pelleting offers a practical application in transport of bark wastes. Bark molding involved several types of products with bark extension of the plastic. Preliminary economic analyses appear favorably inclined toward commercial application. Cooperative efforts are continuing with a number of forest products and engineering companies interested in use of bark as raw material. Chemical utilization has involved studying the detailed chemical composition of Douglas fir bark. A hexane soluble wax fraction that contains two long chain fatty alcohols and phenolic-like compounds and a benzene soluble wax fraction which has a pleasant, aromatic odor were isolated. Various bark carbohydrates were extracted from the inner bark of Douglas fir when successively extracted with 80/20 ethanol/water, 2/1 benzene/ethanol, hot water, dilute ammonium oxalate, and acidified sodium chlorite. Treatment of bark with gaseous ammonia increased the nitrogen content from 0.46% to 4.08%. The treated bark is being separated by various solvent extractions.

SUPPORTED BY Oregon State Government

3.0278, ENVIRONMENTAL POLLUTION PROBLEMS AND ABATEMENT CONTROL ALTERNATIVES
R.M. ALEXANDER, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00833)

OBJECTIVE. Identify the important environmental pollution problems in Oregon and assess their current and potential significance. Relate present federal, state and local abatement and control policies and programs to these problems. Identify alternative policies and programs that may have relevance to these problems and assess their social, economic and political implications.

APPROACH. As the objectives indicate, a review will be made of significant environmental pollution problems in Oregon and current abatement policies. Alternative policies that may be relevant to Oregon's situation, and possible economic, social and political implications of these policies, will be considered.

PROGRESS. This project was activated in 1967 to cover a study undertaken for state government in Oregon on waste disposal policy. The project was completed with publication (April, 1968) of a report entitled, 'Waste Disposal and Environmental Quality in Oregon--An Assessment of Public Policy'. This report reviewed '...the nature of the wastes that produce environmental pollution in Oregon and on the abatement and control technology available... and ...an assessment of present public policy in Oregon, possible improvements, and alternatives that may offer certain advantages.'

SUPPORTED BY Oregon State Government

3.0279, DOUGLAS FIR BARK AS A FILTER MEDIA FOR THE DISPOSAL OF ANIMAL WASTES
M.G. CROPSEY, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00901)

OBJECTIVE. To prevent the pollution of streams and undergtound water by the liquid wastes from livestock enterprises by using Douglas fir bark as a trickling filter in the waste disposal system.

APPROACH. Experiments will be conducted to determine the relative effectiveness of various parameters in the use of Douglas fir bark as a filter media. Some of the parameters tested will be: Ratio of manure to water. Ratio of quantity of bark to the quantity of manure and water. Rate of flow of the liquid through the filter media. Size of bark particles. Life of bark as a filter media. The results will be determined by the reduction of B.O.D., nitrogen and phosphorus of the effluent and the undissolved solids. The experimental data will be extrapolated in order to design a livestock waste disposal system. When sufficient data has been obtained, a model plant will be set up to determine the effectiveness of this method of reducing the wastes of a livestock enterprise.

PROGRESS. Samples of water polluted 1, 2, 4% by weight with poultry manure are being tested to determine the effect of rates of flow, bark size, and quantity of bark in the cleaning of water. The water is tested immediately after being polluted and after five days of filtering for its B.O.D., turbidity, residue upon evaporation, and its nitrogen and phosphorous content. In as much as these tests have not been competed at this date, no conclusions can be made.

SUPPORTED BY Oregon State Government

3.0280, MANAGEMENT PRACTICES AFFECTING SWINE PRODUCTION
D.C. ENGLAND, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00527)

OBJECTIVE. Increase number farrowed per litter and reduce incidence of undersized pigs. Improve pre-weaning survival and growth. Development and testing of new and improved methods and facilities for feeding, cleaning, and manure disposal for hogs raised in confinement.

APPROACH. Data will be collected on ovulation rate, embryo mortality, number of live and dead pigs, and individual birth weights of pigs in relation to number of pigs nursed in the preceding lactation, number of services required, grouping of sows not previously together as opposed to individually housed animals and groups of animals previously housed together, effect of drugs to relieve stress at breeding time, prophylactic use of antibiotics at breeding time, and induction of mating during lactation. Influence of environmental factors upon preweaning growth and survival will be investigated through studies of: artificial feeding of pigs of different birth weights, temperatures most nearly optimum for pigs of different birth weights, amounts of milk obtained by pigs of different birth weights and at different udder section locations, methods of artificial feeding and effectiveness of protective facilities to prevent crushing & chilling. For growing finishing swine, studies will be made of feed wastage & means of preventing it, space requirement with different types of floorings, comparisons of various kinds of bedding areas, & handling methods to induce pigs to use preferred areas of manure deposition. Self-cleaning floors and automatic disposal of collected fecal and urinary wastes will be developed and tested.

PROGRESS. Prolificacy and breeding performance have remained high with total confinement on slotted floors. Birthweights of litters from gilts, but not from sows, were in-

creased by feeding 2, 2-dichlorovinyl dimetyl phosphate (DDVP) during last three weeks of gestation. Postnatal survival was affected similarly. DDVP in ration of gilts prior to breeding did not increase ovulation rate; inclusion after breeding did not affect embryo survival to 25 days. Inclusion of DDVP in ration of market hogs, both full- and limited-fed, did not change average daily gains or carcass traits. Energy stores thus do not appear to be mobilized by DDVP for metabolism in animals of these ages. Further studies underway to better define mode-of-action of DDVP in swine.

SUPPORTED BY Oregon State Government

3.0281, CHEMICAL TRANSFORMATION OF SOLID WASTES

V.H. FREED, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00860)

OBJECTIVE: A study of chemical transformation of solid waste with the view of conversion of solid waste to products of economic value or reduction of volume for easier handling. Includes classification of solid wastes, investigation of methods of chemical transformation of solid wastes, and development of pilot plant operations including studies of engineering and economic aspects.

APPROACH: Following the initial classification and identification of solid waste, studies on chemical transformations will be undertaken, initially on simple wastes such as paper, straw and bark. Significant findings will be applied to municipal solid wastes. These studies should lead to a pilot plant operation utilizing chemical transformation techniques.

PROGRESS: The study of hydrogenation of solid wastes to oils was continued. Bark, straw, rubber, and paper were used. Catalysts such as hydrogen iodide, tetrahydronaphthalene, tin chloride, and platinum were used. Oil yields from 15-20% are attainable using gaseous hydrogen, a catalyst, 350 C, and 4500 psi pressure. The oil produced by hydrogenation of bark using HI-(2) catalyst was analyzed by a commercial laboratory and found to contain 65% aromatics and 35% saturated hydrocarbons. The use of cellulose chemistry to produce products from wastes was continued. Straw, pulp, and paper have been used to produce such derivatives as cellulose acetate, cellulose acetate-butyrate, cellulose maleate, cellulose succinate, methyl cellulose, cellulose phthalate, and benzyl cellulose. Many can be formed into a solid disc under pressure and elevated temperature. Three methods of acetylating the cellulose were evaluated, a solution process, a fiber process, and a vapor phase process. Cellulose crosslinking can be achieved with diisocyanate. A solid disc was produced from the product of straw and tolylene-2,4-diisocyanate. Furfural was produced from the pentosan extract of straw and a pentosan removal technique was evaluated. Destructive distillation of straw and tires produced over 50% condensible liquids and over 30% solid residue. The rubber ash was 20% and the straw ash 6%. The remainder apparently carbon. Wastes such as straw can be mixed with resins and formed into solid sheets under pressure and elevated temperatures.

SUPPORTED BY Oregon State Government

3.0282, CHEMICAL TRANSFORMATION OF SOLID WASTES

V.H. FREED, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

Solid waste disposal problems can be alleviated to some degree if methods can be developed to transform waste materials into usable products or if waste components can be reclaimed for reuse.

The objective of this project is to study the reclamation of solid wastes through chemical treatment. Some of the basic work, such as literature searching and laboratory experimentation, has been completed and several processes for transforming wastes to usable products appear to be potentially useful. These processes will be studied in more detail to evaluate economic and engineering factors.

A large part of many solid wastes is cellulosic in nature; therefore a study of the chemistry of cellulose has been undertaken in detail. It is possible that waste cellulose could be used as raw material for the production of such cellulose derivatives as cellulose acetate, cellulose nitrate, ethyl cellulose, cellulose xanthate, and carboxymethyl cellulose.

Hydrogenation, ammoniation, and destructive distillation of solid wastes are other potentially useful chemical treatment processes that are being studied.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0283, MACRO-FAUNA IN WASTE STABILIZATION LAGOONS

R.L. GOULDING, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

Waste stabilization lagoons are man-made environments that are becoming a more prominent feature of land use. The fauna adapted to this habitat has received little attention. In view of the potential importance of the macro-fauna which may be beneficial in that they contribute to the biological breakdown of organic matter or harmful as potential disease vectors or nuisance organisms, it is imperative that a thorough ecological study of this habitat be carried out.

The long-term objectives of this proposal are to measure the contribution of the macro-fauna in the breakdown of putrescible organic wastes; to understand the pathways through which this is effected; and to assess the beneficial and detrimental results caused by the macro- fauna in lagoons of various designs.

The major emphasis will be a study of the production ecology of Glyptotendipes barbipes; the most abundant macro-invertebrate in the lagoons.

3.0284, LASER MEDIATED LIGNIN SOLID WASTE FERMENTATION

D.A. KLEIN, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00894)

OBJECTIVE: Lignin residues derived from the pulp and paper industries have not been utilized fully, leading in many cases, to stream pollution and solid waste disposal problems. Prior studies on microbial degradation of lignin have shown these compounds to be degraded slowly, even under optimal laboratory conditions. The major objectives of this study are to obtain data on the effects of lasers and irradiation energy sources on the configuration of lignin substrates, and to evaluate effects of such modifications on microbial transformation and degradation processes.

APPROACH: By modifying the secondary and tertiary structures of lignin substrates in aqueous solution, is planned to develop processes by which the lignin polymer can be degraded completely, for use as a carbon source, or be modified by microbial transformations to yield chemical intermediate of commercial interests.

PROGRESS: Work with both fungal and bacterial growth systems in pure cultures has indicated that photolysis during low or high pH conditions, in comparison with pH 7.0, permits retention of a greater portion of ligninsulfonate carbon. By use of varied photo-oxidative conditions, it has been possible to render residual ligninsulfonate carbon up to 70% bio-utilizable. Without photolytic modification negligible bio-utilization is observed. Light wavelengths of under 210 nm are required, and as little as 0.5 Watt of output power should give the potential for an efficient single-pass treatment system. Information on the nature of biological responses to photooxidized ligninsulfonates has also been obtained. Fungi appear to utilize lower- weight polymeric products produced earlier in photomodification as well as aromatic lignin subunits, while bacterial responses appear to be related primarily to the utilization of aromatic subunits produced in later stages of the photooxidation process. Microbial economic utilization coefficients with photolytically-produced lignin sulfonate fragments can be equated to use of conventional carbon sources. Model compound studies using alpha-conidendrin have confirmed accumulation and utilization of aromatic subunits derived from photolysis.

3. SOLID WASTE MANAGEMENT

SUPPORTED BY Oregon State Government

3.0285, ENVIRONMENT AND MANAGEMENT OF LAYING HENS

J.E. PARKER, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00021)

OBJECTIVE: Determine laying hen response and develop recommendations with respect to feeding systems, water consumption, lighting schedules, poultry waste disposal, cage space allowances and other environment factors.

APPROACH: Continue the lighting programs with emphases shifted toward evaluating intensity; evaluation of feeding systems involving periodic changes in dietary protein or energy; cage management practices involving regrouping or relocation as well as water saving practices such as restriction and recirculation.

PROGRESS: A study was conducted in 2'x2' cages using 4, 6, 8 and 10 hens per cage (1, .7, .5 and .4 sq. ft./hen) with and without roosts installed in the cages. Hen-day egg production was 66.2, 61.4, 61.0 and 57.0% for 4, 6, 8 and 10 hens per cage, respectively, but did not differ significantly for any treatment. The addition of roosts significantly decreased feed consumption and tended to improve feed conversion. Feed conversion was significantly better with 4 than with 10 hens per cage. Body weight gain was significantly lower with 10 than with 4, 6 or 8 hens per cage. Egg weight and percent cracked eggs were not significantly affected by any treatment. Another study was conducted using 1, 2 and 3 hens per 12'x18' cage (1.50, .75 and .50 sq. ft. per hen) with and without the addition of roosts and with a normal or a high nutrient density (HND) feed. The HND feed significantly reduced feed consumption and improved feed conversion. There was a significant roost X feed interaction for feed conversion. Adding roosts to cages with normal feed significantly improved feed conversion, but with the HND feed there was no effect from adding roosts. Also, eggs tended to be heavier from hens with roosts on normal feed than in the other groups. Egg production, body weight gain and percent cracked eggs were not significantly affected by any treatment. These studies indicate that it might be practical to provide only .5 sq. ft. per hen in cages, that adding roosts might improve feed efficiency and that it is not practical to use a high nutrient density feed.

3.0286, MICROBIOLOGICAL TREATMENT OF POTATO WASTES

D.S. MAY, U.S. Dept. of the Interior, Federal Water Quality Admin., *Corvallis, Oregon* 97330

In order to better understand the role of microorganisms in the biological treatment of potato processing wastes, several areas will be investigated. The processing waste streams will be characterized to determine chemical constituency with respect to nutrients, organic materials, and trace materials. Attempts will be made to isolate and identify the predominant organisms existing in present treatment systems and determine their role in stabilization of the waste. Using bench-top treatment chambers the growth of these organisms and the conversion of the waste will be followed closely by chemical and biochemical analysis. Organisms which provide good decomposition will be further studied under the influence of nutrient additives which may enhance microbial activity. The feasibility of incuding cultures of highly active microorganism will be investigated. Consideration will be given to the development of biological flocs which may be recovered from the system and used as food material for livestock.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0287, CHEMICAL AND ENGINEERING ASPECTS OF POTATO PROCESSING WASTES TREATMENT

L.J. NIELSON, U.S. Dept. of the Interior, Federal Water Quality Admin., *Corvallis, Oregon* 97330

This investigation will evaluate the several potato processing wastes for treatment both as separate wastes and as a combined flow. Emphasis will be on increasing efficiency of waste treatment for protection of receiving waters and for reduction of treatment costs. Research will consider possible by-product recovery by use of polyelectrolytes and/or pressurized air flotation. The economics of dehydrating potato starch wastes for recovery of a useable product will be examined.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0288, PULP AND PAPER WASTE CONTROL AND TREATMENT

R.H. SCOTT, U.S. Dept. of the Interior, Federal Water Quality Admin., *Corvallis, Oregon* 97330

Development of State of Arts Document covering principal segments of pulp and paper production, in-plant control and treatment for waste reduction, processes in-plant leading to destructive disposal, or utilization and by-product development. Consideration of available means for waste salvage for re-use, water conservation and in-plant concentration and distribution of waste fraction in weak waste streams. Review of present knowledge regarding waste treatment technology as practiced in the industry.

3.0289, RESEARCH ON AN ANIMAL-WASTE POLLUTION CONTROL SYSTEM

E.D. GROSSMANN, Drexel University, School of Engineering, *Philadelphia, Pennsylvania* 19104

Three areas of investigation are associated with this research effort: the steam drying of the animal waste, characterization of the odors in the dried waste, and toxicological and nutritional studies of the dried waste. Factors to be determined include the effect of manure moisture content on drier operation, the effect of mass velocity on both heat transfer and mass transfer, the influence of superheat in the drying medium (steam), the mechanism of drying, bed depth influence, particle size and shape effects, and the influence of nozzle orientation.

Both organoleptic testing or subjective evaluations and analytical testing by means of gas-liquid chromatography, infrared spectroscopy and mass spectroscopy will quantitatively and qualitatively define the odors present in the dried manure and the liquid waste resulting from the drying operation.

Toxicological studies will involve many chemical tests including pH, alkalinity, iron content, phosphate content, nitrate content, sulphur content, chloride content, water and ether soluable material content, and nitrogen content. Animal feedings will also be used to determine the toxic effects of the dried manure. Those prducts found non-toxic will be evaluated for nutritive value by feeding to rats.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0290, INTEGRATED WASTE MANAGEMENT - WATER SYSTEM USING RADIOISOTOPES FOR THERMAL ENERGY

R.W. MURRAY, General Electric Company, *Philadelphia, Pennsylvania* 19123 (AT(30-1)-4104)

The objectives of this program are to design, develop, fabricate and test an engineering model of a completely integrated Waste Management - Water System (WM-WS) using Radioisotopes for Thermal Energy (RITE). This is to be a complete system capable of collecting and processing wastes from four men for a 180-day simulated space mission. Subsystems include feces, trash and urine collection; water reclamation; storage, heating and dispensing of the water; storage and disposal of the feces and urine residue and all other waste material by incineration.

Spacecraft life support systems require heat for several regenerative and recovery processes. RITE has shown to be a very reliable means of providing this heat with a significant savings in the weight normally required for an electrical heat power supply. The resulting reduction in space vehicle weight greatly reduces the required launch rocket thrust and thereby the overall cost of the space voyage. The proposed program integrates several waste

management and water recovery functions into one coherent system to permit multi-purpose use of components and efficient utilization of the RITE.

The WM-WS Program is to be accomplished in seven (7) phases; namely, (1) Design waste incinerator/waste reclamation (WI-WR) unit, (2) Fabricate and test WI-WR, (3) Evaluate test data, (4) Design total WM-WS, (5) Fabricate WM-WS, (6) Test WM-Ws for 10 days, (7) Test WM-WS with RITE for 180 days.

SUPPORTED BY U.S. Atomic Energy Commission

3.0291, PIPE TRANSPORT OF SOLID WASTE

F.D. KETTER, Univ. of Pennsylvania, School of Engineering, *Philadelphia, Pennsylvania* 19104

The broad objective of this proposal is to examine the applicability of the technology of bulk solid transport in pipelines to the collection and removal of solid waste. Whether the pipeline transport of solid waste may be considered as a serious alternative to the truck collection, depends upon the answers to two questions which are fundamental: 1) Is pipeline transport of solid waste technologically feasible? and 2) How does solid waste pipeline compare economically with the present truck collection?

As the result of Grant UI 00541 it was established that under one special set of conditions (those prevailing in the center city of Philadelphia) the collection and removal of solid waste in a combined pneumatic and slurry system is technologically feasible and economically attractive.

It is intended to extend the range of the study examining in particular 1) the technological feasibility of pipeline collection and removal of solid wastes of varying compositions different than those already studied, 2) the feasibility of pumping solid waste slurries with higher concentrations than 12% which is already established - including problems in crushing and pumping, 3) search for reliable criteria for the design of solid waste pipeline which at the present time is lacking, 4) extension of economical comparison of pipeline system with the truck collection to situations different than business districts of the large cities using the methods of system technology, and 5) a study of possible utilization of pipeline as a biological reactor for stabilization of organic matters during conveyance of the solid waste slurry.

3.0292, VORTEX INCINERATION OF COMBUSTIBLE WASTES

C.H. SCHWARTZ, U.S. Dept. of the Interior, Bureau of Mines, *Pittsburgh, Pennsylvania* 15213

To conduct research on incineration. A pilot-scale vortex incinerator with a nominal capacity of 200 pounds of refuse per hour has been designed, constructed and tested. It is refractory-lined, provided with continuous charging, agitation, and has ports for directing secondary air to the center of the vortex.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0293, PYROLYSIS OF SOLID WASTES

D.E. WOLFSON, U.S. Dept. of the Interior, Bureau of Mines, *Pittsburgh, Pennsylvania* 15213

The pyrolytic conversion of noxious and harmful municipal and industrial refuse and other organic based pollutants into potentially useful materials without adding to environmental pollution.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0294, UTILIZATION OF AGRICULTURAL WASTES IN CROP PRODUCTION

H.D. BARTLETT, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01585)

OBJECTIVE: Develop and evaluate methods for efficient handling and utilization of animal and poultry manures as sources of crop nutrients; develop and evaluate methods for combining manure with various vegetable wastes to obtain organic fertilizers and soil amendment products of nutrient value in crop production.

APPROACH: A liquid manure handling system will be constructed, in conjunction with a dairy stall-barn, for study of handling methods and equipment in relation to operational performance, energy requirements and efficiency. Methods and equipment will be developed for making sub- surface applications of liquid manure to agronomic soils. Surface and sub-surface applications of liquid manures at different treatment rates, will be made to plots of various crops. Effect of respective treatment methods and rates will be evaluated in terms of crop growth response and crop quality. Studies will be made to develop methods for making use of numerous agricultural wastes for compost or other organic fertilizer products of value in crop production.

PROGRESS: Liquid manure treatments were made to replicated corn plots at 20, 40 and 60 ton per acre with fall application-fall plowed, fall application-spring plowed, spring application-spring plowed, top dressing after planting and when plants were 15 in. high. Yields were not significantly different between treatments, although there was a trend toward higher yields with higher application rates. Trials, using liquid poultry manure as a nitrogen supplement for mushroom compost, with horse stable litter as a base, did not produce a satisfactory compost. Mechanical break up of the slurry will be necessary for even distribution of the slurry throughout the stack. Furthermore, uniform heating was not attainable, either due to uneven application of the supplement or the microbial activity. An additional 1500 Douglas fir seedlings from various seed sources were planted and fertilizer treatments were applied. Soil samples were analyzed to determine treatment effects on nutrient levels. Growth measurements have been made and are currently being analyzed. Mowing and herbicide treatments were used to control competing vegetation. Manure treatments have caused problems of stimulating weed growth which provide cover for mice and voles that damage trees; it has not yet been determined whether increased growth rate may offset these disadvantages.

SUPPORTED BY Pennsylvania State Government

3.0295, FEED AND WASTE HANDLING IN THE DAIRY OPERATION

H.D. BARTLETT, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01670)

OBJECTIVE: Evaluate and develop methods and equipment for mechanization of handling materials in dairy livestock feeding operations, particularly stall barns. Evaluate and develop methods and equipment for handling and distribution of wastes from dairy production systems.

APPROACH: Studies will be made of existing feeding equipment installations to evaluate labor requirements and equipment costs for feeding dairy cattle in stall barns by mechanical feed carts and with various manager conveyor feeding systems. Work will be done on the development of mechanical feed conveying equipment. Studies of dairy waste management will include handling of animal excrement and the waste water used in cleaning milk houses and milking parlors.

PROGRESS: A mechanical feeder for supplying silage and grain to cows in stall barns has been designed and is being installed. The distribution system is a flight-chain with adjustable volumetric feed compartments for each cow. It will distribute measured quantities of each type of feed to individual cows according to production needs. Using the same conveyor for both types of feed and combining feed compartment construction for each pair of cows greatly reduces the cost of the mechanical equipment. Analyses were made of the power requirements of such a system by laboratory tests of friction forces for the respective feeds and related construction materials. A prototype was constructed to determine flow characteristics of the respective feeds in this type of system. The feeder will be evaluated for functional and mechanical operation in the next three months. An expandable orifice nozzle has been designed and installed in a system to dispose of milking parlor and milk house wastes by distribution on land through a sprinkler irrigation system. The orifice size is controlled by a spring loaded retainer which allows the orifice to open when line pressure increases due to restriction or stoppage by accumulation of solids in the orifice. Further development is necessary on the elastic liner. This system is being

tested under winter conditions. The system will be evaluated in relation to pollution problems of odors, flies and ponding.

SUPPORTED BY U.S. Dept. of Agriculture

3.0296, SUBSURFACE DISPOSAL OF ANIMAL MANURE
H.D. BARTLETT, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01787)

OBJECTIVE: Develop and evaluate disposal and utilization systems for land application of treated and untreated dairy and poultry manure that will minimize the pollution of water, soil and air.

APPROACH: Manure will be applied, up to 100 T/acre/year, approximately 4 inches below the surface of soil in forage grass vegetation when soil conditions permit operation on the land. Applications also will be made to corn plots before planting, after planting, and after harvest. Frequency and amount of application will be varied on replicated 1/2 acre plots. Nitrate will be analyzed on soils sampled with regard to depth of sample, season, and treatment. Crop yields and tissue analyses also will be used in determining soil productivity and nitrogen removal.

PROGRESS: Treatments of liquid manure (dairy cows) were applied approximately 4 in. below the surface of a recently established seeding of Pennmead orchard grass during the period May-Sept. 1969. Application rates of 15, 30, 45, 60 and 75 T/A were made in 15 ton increments with successive applications made when soil conditions permitted passage of equipment over the previous application. The treatments were arranged in randomized block design with four replications on 20 ft. x 50 ft. plots. Suction lysimeters were installed in each plot at depths of 1, 2, 3 and 4 ft. (1 each per plot, Aug. 1969). Water samples were taken from the lysimeters at weekly intervals beginning Oct. 27, 1969. The samples are being analyzed to determine NH(4), NO(3), P, organic nitrogen, Cl and pH. Analyses will be made for Cations: Ca, Mg, Na and K. Also, tissue analysis will be made on orchard grass samples taken from each plot. Samples of the waste were taken for crop nutrients and BOD analysis. The same treatments rates for the respective plots will be repeated in the spring and summer of 1970. Also, the water, crop tissue and soil moisture analyses will be continued.

SUPPORTED BY U.S. Dept of Agriculture

3.0297, AGRICULTURAL WASTES - POULTRY MANURE DISPOSAL AND USE
G.O. BRESSLER, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01588)

OBJECTIVE: Develop methods of drying and handling poultry droppings in a poultry house; determine relationships among temperature, moisture, air movement and drying rates of fresh poultry droppings; determine effect of drying poultry droppings upon kind and levels of micro-organisms, odors, amount of fly infestation; incinerate dry droppings and determine caloric value of droppings, chemical composition of ash, economic feasibility of method, methods of merchandising.

APPROACH: Two poultry houses with flocks of about 3000 leghorn layers in each will be used initially for conducting experiments. Adjustments will be made in equipment placement and ventilation design to provide a positive system of drying droppings. Drying rates of poultry droppings will be related to temperature and moisture conditions. Kind and level of micro-organisms will be determined by using recognized air sampling techniques. House odors will be determined by gas chromatographic analyses. Dry droppings will be incinerated and heating value determined. Ash remaining after incineration will be analyzed for chemical composition and value of ash for plant growth determined by running pot and field experiments in combination with plant tissue analysis.

PROGRESS: Improve the efficiency of drying poultry manure, average air velocity over the manure was increased from around 200 to over 500 feet per minute. In present experiments manure can be dried to about 30% moisture in wintertime without use of heat cable, for about 1/4 cent per dozen eggs. The main problem now is to achieve further drying to about a 10% level at a lower cost than that achieved by use of heat cable in the floor of the poultry house. Experiments with ashed poultry manure have indicated that: (1) foliar analyses of beans grown in soil treated with ash showed significant increases in levels of K, Mg, G and Na, Ca and Mn decreased significantly. (2) Ashed chicken manure increased the soil pH and also soluble salts.

SUPPORTED BY Pennsylvania State Government

3.0298, CONSERVATION AND RENOVATION OF WASTE WATER
L.T. KARDOS, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01481)

OBJECTIVE: Determine effect of irrigation with sewage plant effluent on yield and other plant response parameters of agronomic and forest vegetation; determine to what extent agronomic crops, trees, and soil mantle can renovate sewage plants effluent and permit its recharge to ground water; determine effects of application of sewage plant effluent on physical, chemical and biological properties of soil; compare effectiveness of various surface and sprinkler distribution methods for disposal and renovation of sewage plant effluent.

APPROACH: Agronomic and forested areas will be irrigated with chlorinated sewage plant effluent at weekly intervals with sufficient quantities to secure recharge to ground water but at rates of penetration which will permit renovation of effluent in biologically active portion of soil mantle prior to its recharge to ground water. Effects of the effluent on crop and tree growth and on soil properties will be determined. Engineering studies will compare several methods of applying the effluent to determine their effectiveness as distributing systems on a year round basis.

PROGRESS: Chlorinated effluent was applied to forest and crop areas in quantities from 1 to 4 inches per week. Drought occurred in four of the years and increases in crop yields ranged up to 300%. Harvested crops removed nitrogen equivalent to 100% of the applied nitrogen and 80% of the applied phosphorus. Red pine diameter and height growth were increased by one inch of effluent at weekly intervals but responses to 2 inches per week were unfavorable. Young hardwoods responded favorably to all levels of application whereas the mature hardwoods did not. Terminal height growth of the white spruce was increased to 400%. Removals of nitrogen and phosphorus, two constituents primarily responsible for eutrophication of streams, were excellent. After 5 years, water percolating through the soil at the 4- foot depth on plots receiving 2 inches of effluent weekly had an average concentration in Nov.-Dec. 1967 of only 0.06 mg/1. of phosphorus and 6.4 mg/1. of nitrate-nitrogen. Recharge of the groundwater table from plots receiving 2 inches per week was equal to 90% of the applied effluent. Physical, chemical, and biological properties of the soil were not adversely affected.

SUPPORTED BY U.S. Dept. of Agriculture

3.0299, USING CROPLAND FOR SEWAGE WASTEWATER AND SLUDGE DISPOSAL
L.T. KARDOS, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01809)

OBJECTIVE: Determine interaction of soils and plants with sewage wastewater and sludge disposed on cropland and forestland, with emphasis on P, boron, and N reactions in the soil and with the biosphere and on the soils potential for removing N from wastes by denitrification; develop systems for land disposal of wastewater and sludge.

APPROACH: Cropland and forestland will receive various amounts and proportions of sewage wastewater and sludge. Yields and composition of agronomic crops and forest foliage, wood, and litter will be used to evaluate annual nutrient removal in harvested crops and nutrient absorption, storage, and recycling in forest stands. Chemistry and kinetics of P fixation on and penetration into soil will be studied. Adsorption and desorption of boron in layers of the soil mantle and its significance in potential boron toxicity will be evaluated. Effect of various combinations of wastewater and sludge loading on nitrification and denitrification will be examined. Hydrologic effects such as perched water tables, interflow and runoff will be measured.

PROGRESS: Hydrologic studies were initiated on a reed canarygrass site to determine the most effective sequence of irrigation of sewage effluent for producing minimum runoff with max-

imum renovation. The reed canarygrass area continues to be the most effective in controlling NO(3)-N through puts to the groundwater. During September-October average NO(3)-N concentration in the soil water at the 4-foot depth was 1.42 mg/1. in the reed canarygrass area which was receiving 2 inches of effluent at weekly intervals but was 9.06 mg/1. in a similarly effluent treated silage corn area. Forested areas receiving 2 inches of effluent weekly have had NO(3)-N concentrations exceeding 10 mg/1. at the four- foot depth. Red pine receiving 2 inches of effluent became severely chlorotic in 1968 whereas the one-inch treated area showed on chlorosis. Several denitrifying microbes were isolated from effluent treated soil by enrichment culture under anaerobic conditions and their denitrifying capacities determined under various conditions of temperature, oxygen tension and pH.

SUPPORTED BY U.S. Dept. of Agriculture

3.0300, SOLUBLE PHOSPHORUS REMOVAL IN THE ACTIVATED SLUDGE PROCESS

R.R. KOUNTZ, Penn. State University, School of Engineering, *University Park, Pennsylvania* 16802

This project will develop a process for the removal of phosphorus from municipal waste waters utilizing chemical precipitation of the phosphorus within the aeration and settling units normally used in the activated sludge process. The work will be conducted at the waste water treatment plant owned and operated by The Pennsylvania State University. Studies will be conducted to determine the relative merits of sodium aluminate and filter alum as precipitating agents, the efficiency of the coagulant in removing phosphorus over a one year operating period, the effect of the sludge digester on the inorganic precipitate. Costs and operating information for a 2.1 mgd domestic waste plant will also be ascertained.

SUPPORTED BY Soap & Detergent Association

3.0301, SEPTIC TANK SYSTEMS AND PRODUCTIVITY OF PENNSYLVANIA SOILS

R.P. MATELSKI, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01632)

OBJECTIVE: Determine and predict the soil factors responsible for adequate septic tank usage. Identify the soil properties responsible for observed variations in productivities.

APPROACH: Field measurements and later laboratory soil determinations of the effect of seasonal variation, perched water tables and the variability within a mapping unit on waste water movements will be studied to predict efficiencies of septic tank tile disposal fields. The field percolation tests will be studied and improved. Yields of important crops on soils with variations in slope, erosion, fertilizer treatments and management will be measured and evaluated. Soils will be characterized in the laboratory to determine the soil factors contributing to yield variation.

PROGRESS: Further statistical evaluations of 250 sites on 90 soil series in 25 counties indicated considerable percolation test rate variation of individual tests within a single site. Field designated permeability classes recorded at the time the soil was described were generally lower than the determined percolation rates. Soil drainage classes were found to be closely related to percolation rates, with 82% of the moderately well, somewhat poorly and poorly drained sites having rates slower than 2.5 cm/hr and 76% of the well drained sites having rates greater than 2.5 cm/hr. Measured yields of ear corn for 1967 and 1968 in Chester and Mifflin Counties on 20 soil series were subjected to multiple regression analyses. Of the 60 soil, management and weather factors; July precipitation, plant population, percent of subsoil clay, available potassium, pH of the subsoil, amount of disease, depth of solum, percent of organic carbon and percent of coarse fragments explained 72% of the yield variation. Additional percolation testing for septic tank use recommendations was continued in Snyder, Butler and Bedford Counties. The presence of deep fragipans prevented certain supposedly well drained soils from passing the percolation standards of the Pa. Dept. of Health.

SUPPORTED BY Pennsylvania State Government

3.0302, HIGH-RATE, MULTIPLE MEDIUM FILTRATION FOR SECONDARY TREATMENT OF MUNICIPAL WASTE WATER

J.B. NESBITT, Penn. State University, School of Engineering, *University Park, Pennsylvania* 16802

This project will study the treatment capability and economic feasibility of a high-rate, multiple medium filter for the secondary treatment of municipal waste water. The study will be conducted on a model filter constructed at the Pennsylvania State University sewage treatment plant. Effluent from the primary settling basins in the plant will be chemically coagulated and passed through the model filter.

The following analyses will be made of the influent to and effluent from the filter: (1) biochemical oxygen demand (BOD), (2) chemical oxygen demand (COD), (3) soluble and total phosphorus, (4) ammonia and nitrate nitrogen, and (5) turbidity.

Studies will be made to determine: 1. the effect of size of the top medium and different coagulants on effluent quality as measured above and on the length of filter run. 2. the washing rate and time of wash that will produce the most economical operation. 3. the feasibility of vacuum filtration for the disposal of filter wash water. 4. the economics of a waste water disposal system utilizing primary treatment; high-rate, multiple medium filtrations; and separate sludge digestion with vacuum filtration of digested sludge.

SUPPORTED BY Pennsylvania State University

3.0303, SYSTEM OF SWINE PRODUCTION DESIGNED TO IMPROVE COMPETITIVE POSITION

G.W. SHERRITT, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01759)

OBJECTIVE: Develop a system of swine production that will, through control of environment, provide high levels of feed efficiency, productivity, and health; through feed and manure handling systems, minimize labor requirements.

APPROACH: Develop and evaluate a 'farrow-to-finish' housing and management system in terms of feed requirements per pound of pig marketed, age of pigs marketed and pigs per litter marketed. The ventilation, feeding and management practices that will make the system work will be developed through continuous recording and changes as necessary. An evaluation of the economics of the total system will be made when it has been completed and is functioning.

PROGRESS: Data was accumulated on two crops of pigs in the farrow- to-finish system of production over the last year. Additional information on control of air movement and humidity through alternate ventilation methods was studied. Completion of the project, summarization of the results, and publication is expected in the coming year.

SUPPORTED BY Pennsylvania State Government

3.0304, EVALUATION AND DEVELOPMENT OF SPECIAL PURPOSE COALS

W. SPACKMAN, Penn. State University, School of Earth Sciences, *University Park, Pennsylvania* 16802

This contract will entail the collection of coal samples of all ranks from all over the United States, with particular attention paid to those areas that contain coal types that may be of value in existing or potentially feasible processes involving coal gasification liquidification, sewage treatment, etc. Not less than twenty coal types will be selected from the total samples on the basic of availability, potential for economics separation, use potential, and petrographic and chemical distinctiveness.

These samples will be subjected to standard petrographic analyses and to proximate and ultimate chemical analyses. The samples will also be subjected to any additional analyses which will yield information of value in determining each coal types' reaction in any given process. Petrographic and physical properties will also be studied as an heterogeneous coal product. The

bulk coal samples will be processed by commonly employed preparation and separation techniques in an attempt to concentrate the selected coal types, these techniques being altered and modified as information from the physical analyses of the coal types become available.

Split of the coal types selected for this contract will be made available to other OCR contractors upon request and chemical, petrographic and physical evaluations will be made of coals being investigated in connection with other OCR projects.

SUPPORTED BY U.S. Dept. of Interior - Off. of Coal Rch.

3.0305, RECOVERY AND UTILIZATION OF PROTEINS AND OTHER VALUABLES FROM POTATO STARCH FACTORY WASTES

E.O. STROLLE, U.S. Dept. of Agriculture, Eastern Utilization Res. Div., *Wyndmoor, Pennsylvania* 19118 (E3-6-55)

OBJECTIVE: Develop an optimum method of recovering proteins from potato starch factory wastes to reduce the BOD of effluents. Construct a prototype plant for demonstration, market development, cost and design optimization.

APPROACH: Study protein recovery by heat coagulation, foam fractionation, simultaneous concentration and coagulation, dewatering and drying methods. Optimize process for cost and design. Construct prototype unit. Utilization and market development. Demonstrate process to potential users.

PROGRESS: A survey of starch factories was made to determine the composition of protein water in America. Soluble solids ranged from 1.5-2.8%. Sedimentation studies were made on proteins coagulated by steam injection heating. The effect of soluble solids and pH on % coagulated, settling mechanism, detention time and purity of protein were evaluated. The filtration of protein slurries was studied in a plate and frame filter press. The slurries were readily filterable over a pH range 3.0-5.0 and temperature range of 50-180 F. Other work revealed that for efficient operation of the ion exchange columns used to recover the other valuables, a residual protein level of 180 ppm or lower was required. These studies have shown the feasibility of quantitatively recovering the proteins by steam injection heating to 180-220 F at a pH 3.0-4.0, followed by conventional solid-liquid separation methods, after which the other constituents may be removed by ion exchange. Equipment to study foam fractionation of the proteins has been assembled. Synthetic polyelectrolytes were tested and found to be ineffective in precipitating the proteins. Cost studies will be made and used together with design data to optimize the protein recovery process.

3.0306, DESIGN OF FACILITIES FOR ANIMAL WASTE DISPOSAL

D.J. VANREST, Univ. of Puerto Rico, Agricultural Experiment Sta., *Mayaguez, Puerto Rico* (PR-C-00410)

OBJECTIVE: Develop design and management criteria for anaerobic digesters as a primary method of animal excrement stabilization in Puerto Rico, evaluate by means of pilot systems combinations of secondary methods of stabilization and utilization of effluent from anaerobic primary systems.

APPROACH: A series of pilot plant digesters will be installed to determine optimum conditions for certain design parameters, viz, method of initiating fermentation; loading rates per cubic foot of digester volume and circulation rates of digesting material. Parallel trials on secondary systems will be made on the effluent from the primary system with aeration, settling and plant and fish cultures.

PROGRESS: Efforts have been concentrated on gathering field data from a single plot digester to improve the quality of the assessment of solid reduction, B.O.D. reduction and operational characteristics. Equipment was installed to oxygenate part of the digester to test the value of a two-stage process. On four occasions now anaerobic fermentation has been initiated from a single pail of 'seed' material, and successfully managed for a six month period without undue odors or difficulty by the single expedient of monitoring the pH and adding sodium bicarbonate when necessary to counteract excessive acidity. The method of waste disposal can therefore be considered as practical and proven.

SUPPORTED BY Puerto Rican Government

3.0307, DEMONSTRATION OF A NEW PROCESS FOR THE TREATMENT OF HIGH POLLUTANT CONCENTRATION TEXTILE AND FINISHING WASTES

C.P. POON, Univ. of Rhode Island, School of Engineering, *Kingston, Rhode Island* 02881

The principal objective of this project is to establish a new, compact economical waste treatment system for textile dyers and finishers.

The process is a compact system occupying no more than 2,700 sq.ft., which is available in an existing mill building. It will use an anaerobic-aerobic oxidation unit incorporating activated carbon, and an activated carbon adsorption filter multiple column unit. The carbon units can be easily regenerated in-place by biological oxidation.

The project will use a full scale unit to treat the entire waste stream (125,000 gpd) at Palisades Industries in Peace Dale, R.I.

The start of construction is scheduled for 1 December 1969, and the project should be completed on 1 November 1970.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

3.0308, THERMOPHILIC AEROBIC PROCESS FOR WASTE TREATMENT

J.F. ANDREWS, Clemson University, School of Engineering, *Clemson, South Carolina* 29631

Mesophilic aerobic digestion has been shown to be feasible for the treatment of primary and waste activated sludge. Digestion rates, reduction in volatile solids, destruction of pathogenic organisms, and solids-liquid separation should be improved by operation at thermophilic temperatures. Theoretical calculations show that sufficient heat can be obtained through thermogenesis to maintain thermophilic temperatures. This process would also have great potential for the combined treatment of garbage and sewage sludge.

Theoretical mathematical models will be developed for the steady- state process using basic continous culture theory. These models will attempt to predict effluent substrate concentration, organism concentration, and reactor temperature. The effects of limiting oxygen transfer rate at lower detention times will be included.

Mixed cultures of thermophilic microorganisms will be established in continous flow, complete-mixing reactors. The primary variables studied will be temperature, detention time and oxygen supply rate. The theoretical mathematical models previously developed will be modified to conform to observed data.

The response of the steady-state process to perturbations in reaction mixture temperature will be measured. A quantitative measure of process stability will be determined using appropriate process dynamics techniques.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0309, DESIGN OF A WATER DISPOSABLE PACKAGING CONTAINER

S.F. HULBERT, Clemson University, School of Engineering, *Clemson, South Carolina* 29631

The objective of the research is to develop a water glass container which can be readily and economically fabricated, which can be protected from premature dissolution by suitable surface coatings and which will dissolve rapidly when such surface layers are penetrated. The economic and engineering aspects of the resulting water soluble packaging container are being evaluated as well as its advantages over conventional container materials from the disposal point of view.

The superstructure is a water soluble sodium silicate glass. Five basic process methods of applying inert barrier films are being investigated: (A) Chemical Vapor Deposition, (B) Surface Dealkalization, (C) Liquid Ion Exchange, (D) Vapor Ion Exchange, (E) Polymer Coating Applications.

Bottles are presently being hand blown from crucible melts. The project is now moving from the laboratory stage production of water disposable glass containers to the pilot plant stage. The technical and economic aspects of producing these disposable containers with suitable glass melting facilities and machines for

fabricating the bottles combined with coating equipment is now being worked out on a pilot plant basis. Some modification of conventional glass tanks and bottle machines will probably be necessary. Clemson University is planning a symposium during the coming year for the glass container industry and the food packaging industry concerning the results of its efforts to develop a water disposable glass packaging container.

3.0310, WASTE DISPOSAL FROM FOOD PROCESSING PLANTS IN SOUTH CAROLINA

J.R. LAMBERT, Clemson University, Agricultural Experiment Sta., *Clemson, South Carolina* 29631

The objective of this master project which is concerned with water resources is to determine the effectiveness of the soil mantle for purification of waste water from food processing plants. This will be done by studying the effect of the application of waste water on the hydrologic conductivity of the soil, and by studying the effects of various waste disposal application treatments on the quality of downstream flow. The interrelationships of engineering, agronomic, microbiological, meteorological, and climatic factors required for proper design and operation of an efficient and safe system for distributing waste on the surface of South Carolina soils will also be determined. Waste water from a pilot food processing plant will be applied at different application rates and intervals to lysimeters constructed of undisturbed soil with various vegetative covers and the quantity and quality of seepage will be measured. Lysimeters containing disturbed soil will be used to study the effects of soil properties, soil depth, and rate of application of the waste water on composition of the percolate from the soil and the effects of the waste on the physical and chemical properties of the soil.

SUPPORTED BY South Carolina State Government

3.0311, WASTE DISPOSAL FROM FOOD PROCESSING PLANTS IN SOUTH CAROLINA

L. VANBLARICUM, Clemson University, Agricultural Experiment Sta., *Clemson, South Carolina* 29631 (SC00746)

OBJECTIVE: Determine the nature of waste from S. C. food processing plants. Devise and evaluate methods for utilizing waste from food processing plants. Determine methods by which in-plant waste and be modified or reduced. Determine the effectiveness of the soil mantle for purification of waste water from food processing plants.

APPROACH: Initial research will be associated with identifying waste constituents. Determine the economics of the manufacture of certain by-products from the various waste material. Treat chemically with various organic and neutralizing agents various waste samples an effort to modify or reduce the BOD values and neutralize the waste.

PROGRESS: Tomatoes were successfully peeled with both KOH and NaOH caustic solutions. While some differences between the two caustic compounds were noted, it was concluded that KOH could be used in place of NaOH at the same concentrations on a weight basis. Canners who dispose of their liquid waste by sprinkler irrigation on cropland can substitute KOH for NaOH and thereby realize the valuable addition of a plant nutrient to their waste. Peaches are relatively easy to peel with caustic solutions, and it was found that KOH could be substituted for NaOH in peeling operations at the same concentrations on a weight basis.

3.0312, FARM ANIMAL WASTE DISPOSAL AND POLLUTION CONTROL

P.R. MIDDAUGH, South Dakota State University, Agricultural Experiment Sta., *Brookings, South Dakota* 57006 (SD00411)

OBJECTIVE: Characterization of physical, chemical and biological properties of livestock and poultry wastes; improvement in management systems with regard to handling, treatment and disposition of wastes.

APPROACH: Animal wastes will be analyzed for Oxygen Demand, Dissolved Oxygen, Methane, Nitrogen forms, Suspended Matter, Chlorine Requirement, Surfactants, and Water Analysis by methods outlined in 'Standard Methods for the Examination of Water and Wastewater,' Eleventh Edition, 1960, or in 'Official Methods of Analysis of the Association of Official Agricultural Chemists,' (A.O.A.C) Ninth Edition, 1960. Data thus obtained will be used to develop design criteria for stabilization ponds and reduction tanks on the basis of number of animal units.

PROGRESS: Bacterial methods for determining fecal streptococci were studied and three types of surface waters, the James River in South Dakota, a dairy lagoon and a municipal waste discharge, were surveyed for kinds of fecal streptococci. A modified membrane filter technique was developed as a potential, rapid method for isolating and characterizing types of fecal streptococci for their possible use in tracing water pollution sources to distinguish municipal (human) wastes, by identifying Streptococcus fecalis and its biotypes, from bovine (ruminant) wastes by identifying Streptococcus bovis biotypes. A total of 302 representative fecal streptococci were isolated from the three types of surface waters and were biochemically characterized into known species as S. faecalis and biotypes or as S. bovis. The dairy lagoon yielded fecal streptococci which were 39% typical S. faecalis, 35% S. faecalis biotypes, 8% S. faecalis var liquefaciens, 1% S. fecium and 9% were S. bovis which originate from ruminants. No S. bovis was isolated from the municipal human wastewater or from the James River in South Dakota which consisted entirely of S. faecalis or its varieties. Further studies are planned to improve the sensitivity and reliability of method for detecting S. bovis and to determine the survival of S. bovis and S. faecalis in polluted waters as indicators of ruminant versus human fecal pollution. Membrane filter studies indicate rapid identification of S. bovis is possible.

SUPPORTED BY U.S. Dept. of Agriculture

3.0313, ANALYSIS OF COMPLETE LIVESTOCK PRODUCTION SYSTEMS

H.G. YOUNG, South Dakota State University, Agricultural Experiment Sta., *Brookings, South Dakota* 57006 (SD00437)

OBJECTIVE: Obtain service and design information on livestock management systems.

APPROACH: Information will be obtained on following specific areas of management systems. Mechanized and automated feeding systems for Swine, Beef, Dairy Cattle, and Poultry; various confined management systems for feeding swine. Various proportions of slotted floors, farrow to finish housing and various feeding systems; housing systems for dairy cattle to include Free Stall, Loose Housing and Stanchions; livestock waste disposal systems to include waste disposal lagoons, liquid handling and spreading.

PROGRESS: Investigations in Free Stall Calf Housing at the Dairy Research and Production Unit were initiated in the fall of 1968. Variables being studied are variations in stall width, steel and wood slotted floors and sawdust and straw bedding materials. Time lapse photography is being used to study the behavioral patterns of dairy calves 6 weeks to 5 months in age. A thesis will be published on the results of this study by June 1, 1969. Environmental studies of beef cattle are being conducted to determine if various degrees of shelter have any effect on the rate of gain and feed efficiencies of fattening steers. No trends have been established at this time and a bulletin will be forthcoming in the spring of 1970.

Object. To follow the development of new methods.

3. SOLID WASTE MANAGEMENT

SUPPORTED BY Swedish Government

3.0315, TREATMENT OF COTTON TEXTILE WASTE BY ENZYMES AND UNIQUE HIGH RATE TRICKLING FILTER SYSTEM

J.L. YOUNG, Holliston Mills Incorporated, *Kingsport, Tennessee* 37662

The proposed project is to be divided into three phases.

The object of Phase I is to determine which method of desizing is the most satisfactory and economical method to use with both process control and biological treatment as the criteria.

Phase II of the project consists of design and construction of the AquaTair high rate trickling filter system modified to treat a cotton greige goods processing plant waste. The overall objective of this phase is to discharge an acceptable effluent to the receiving stream.

The object of Phase III is to determine experimentally the blend of enzyme necessary to break down the organic sludges produced to render them biologically reactive to further aerobic decomposition.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

3.0316, FARM WASTE DISPOSAL

J.I. SEWELL, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00277)

OBJECTIVE: Develop operational characteristics and design criteria for animal waste disposal facilities in Tennessee.

APPROACH: Three existing liquid manure installations on experiment stations will be operated under varying conditions to determine best procedures for agitating and unloading the pits. In model studies, effect of pit shape, baffles, columns, and different types of agitators will be determined. Predictions based on the model studies will be tested at field installations. Laboratory tests and pilot-plant studies on decomposition of manure in lagoons will be conducted. Based on these studies, a lagoon will be constructed. The lagoon will probably have two stages. The first anaerobic stage will be small, and will be equipped for sludge removal. The second larger stage will operate under aerobic conditions. Design criteria for lagoons under Tennessee conditions will be developed.

PROGRESS: Liquid manure systems costing about $10,000 are in operation at two experimental dairies, each milking between 100 and 150 cows. About 1.5 cubic feet of liquids and manure per cow per day was put into the pits, the period between pit emptyings varied between 30 and 50 days, and the pits were agitated at 2 and 3 week intervals. Little sediment has collected in the pits. The effects of internal obstructions and baffles on manure pit agitation were investigated by laboratory model studies. In tests with 4 different baffle arrangements where the agitator nozzle was located at the end of the baffle and directed flow down the sides of the baffle, the combined use of side and center baffles decreased the deposition of solids significantly over that where either center or side baffles were used alone. A manure slurry irrigation experiment has been initiated, the facilities have been designed, and construction is underway. The system consists of a large concrete holding tank, combination slurry agitator-pump and portable irrigation pipe with one large sprinkler. The holding tank is located so that manure can be slushed into it. During rainfall, the tank will receive the first 1 1/2 inches of surface runoff and manure from the lots. The benefits of manure slurry irrigations on crops and the effect of slurry irrigation on ground water quality will be evaluated.

SUPPORTED BY U.S. Dept. of Agriculture

3.0317, INFLUENCE OF ENVIRONMENT ON PERFORMANCE OF HENS

H.V. SHIRLEY, Univ. of Tennessee, Agricultural Experiment Sta., *Knoxville, Tennessee* 37916 (TEN00144)

OBJECTIVE: Study the performance of hens subjected to: constant controlled temperature and humidity, conventional floor method of management and, conventional laying cages.

APPROACH: The performance of hens in 3 types of laying houses will be studied. The houses, each 24' x 48' are designated conventional (shavings used as litter), individual cages, and slatted floors. The principal variation in treatments between years will be floor space per hen. In the conventional house pullets will receive 2 and 3 sq. ft./hen. In the slatted floor house pullets will be housed at the rate of 1, 1 1/2, and 2 sq. ft./hen. One and 2 pullets per cage will be used in the cage house. Different methods of mechanical manure removal and different wall and roof constructions will also be studied in the slatted floor house. Performance of each house will be measured in terms of number of eggs produced per hen housed, number eggs per sq. ft. floor space, feed consumed per doz. eggs, mortality and returns over costs.

PROGRESS: The performance of layers housed at densities of 1, 2, and 3 birds per 10' and per 12' cage is being studied in a series of two experiments. The first experiment ended in August, 1968 and the second is currently in progress. Generally, the results have indicated that as space per hen decreases there is a decrease in the rate of lay and in body size but with an improvement in feed required per unit of eggs produced. The income over costs has been in favor of two hens per cage. Currently in progress is a study comparing the performance of pullets with that of hens force-molted at the end of the first laying year. Restricting feed intake of mature hens resulted in lowered production, reduced egg size and body weight. Feed per unit of eggs was not affected. Limiting the feeding time did not significantly affect performance as the hens apparently adjusted their feed intake to the available time. Limiting the time water was available resulted in a decrease in egg production and feed consumption. Specific gravity and Haugh units of eggs were not affected.

3.0318, ANALYSIS OF SOLID WASTE DISPOSAL METHODS

W.J. BOEGLY, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

Currently, it is estimated that an average of 4.7 pounds of solid waste are produced per person per day in the United States. This figure is expected to rase to 6.8 pounds per person per day in 2000. Collection and disposal of this material represents a significant and costly problem in dense urban areas. Basic collection and disposal systems have changed little for many years. Open dumps, sanitary landfill, and incineration remain the principal disposal operations. New collection and disposal systems may be needed to handle the growing volume of solid wastes. Bulk volume reduction near the source followed by underground transport through pipelines would appear to offer a potential solution to the solid waste problem in urban areas. Experimental studies with typical materials in municipal waste have been initiated on the possible use of a wet-oxidation process as a volume reduction method.

It has been found that slurries of paper and plastics (which constitute at least 50 per cent of urban municipal refuse) can be oxidized at temperatures around 200 degrees C. Current studies are directed at the potential use of catalysts and changes in operating methods to further reduce operating temperatures.

SUPPORTED BY U.S. Atomic Energy Commission

3.0319, APPLICATION OF HYPERFILTRATION WITH DYNAMICALLY-FORMED MEMBRANES TO TREATMENT OF MUNICIPAL SEWAGE EFFLUENTS

K.A. KRAUS, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831

Oak Ridge National Laboratory will investigate the application of hyperfiltration with dynamically-formed membranes to the treatment of municipal sewage. Primary and secondary effluents will be included in the study, but with special emphasis on activated sludge effluent. An assessment of both organic and inorganic rejection will be made. Various membrane support materials of various pore sizes will be evaluated and the necessity of using filter aids (with the larger pore sizes) and film forming additives will be examined. Diatomaceous earth, polyelectrolytes, and the hydrous oxides of iron (III) and aluminum (III) would be the first choices if such substances are needed. Salts such as nitrate, ammonia, and phosphate will be monitored to investigate the question of specificity of salt rejection. The effects of pressure,

temperature, and influent pH upon product quality and flux will be investigated. To extend the period of high flux, some studies of methods of preventing membrane-fouling via turbulence promoters or backwashing are also proposed.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

3.0320, DISPOSAL OF ANIMAL WASTES BY AGRICULTURAL PRACTICES IN THE SOUTHERN PLAINS

B.A. STEWART, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Bushland, Texas* 79012 (SWC-026-EBUS-3)

OBJECTIVE: Development of management practices for disposing of animal wastes by: determining the maximum quantity that can be applied without impairing crop production; measuring pollutants moving through soil treated with high rates; evaluating the effects on soil properties; determining decomposition rates with and without mixing with soil.

APPROACH: Laboratory, greenhouse, and field experiments will be used. Animal wastes will be applied at varying rates and frequencies. Laboratory studies will deal with rates of decomposition, ammonia volatilization, and microbial transformations of nitrogen. Greenhouse and field studies will be concerned with effects of time and rates of application on crop production. Movement of pollutants through soil toward groundwater will be followed in field studies.

PROGRESS: Playas, naturally occurring shallow lakes, are being used by feedlot operators to impound runoff. Following 1 year of usage during a period when storm runoff occurred, profile samples taken to a depth of 13 feet indicated only minimal seepage into the Randall clay in the playa bottom. Chloride movement was apparent to only 2 feet and significant nitrate levels were found only in the surface foot. These results indicate that these playas may be a real asset to the feeding industry, but additional studies are needed. Soils on the slopes surrounding playa bottoms are more permeable and seepage could be greater when sufficient runoff occurs to submerge these soils. Preliminary field studies concerned with management of manure showed high salt, ammonium, and nitrite concentrations in a clay loam soil treated with high rates of manure and that crop production was limited. Sorghum grain yields were reduced by manure applications of 120 tons/acre or more, and observations showed early season growth reduction on plots treated with 60 tons/acre. Salt concentrations increased to depths of 3 feet or more during the growing season. A greenhouse study showed that during 2 crops of grain sorghum, 1 unit of N from ammonium nitrate was equivalent to 2.4 units of N applied in feedlot waste.

3.0321, CHARACTERISTICS OF WASTE FROM SOUTHWESTERN CATTLE FEEDLOTS

D.M. WELLS, Texas Technological University, Water Resources Center, *Lubbock, Texas* 79409

The purpose of this research is to evaluate the effects of various parameters such as climatic conditions, types of rations, density of cattle, slope, and type of surfacing material on the characteristics of wastes from southwestern cattle feedlots. Specifically, the objectives are to determine the quantity and quality of runoff from beef cattle feedlots as they are affected by the above parameters, and to develop recommendations and design criteria for feedlot waste management control.

performed on nearby commercial feedlots to verify the results of the work on experimental feedlots.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

3.0322, SOIL TREATMENT OF CATTLE FEEDLOT RUNOFF

E. MERRITT, Meat Producers Incorporated, *Melissa, Texas* 75071

Description: The project will consist of evaluating and demonstrating a spray-runoff soil treatment process for the removal of organics and nutrients from rainfall runoff of a 12,000 head cattle feedlot. The project is to be started April 1, 1970 and the anticipated completion date is June 30, 1972.

Objectives: To determine suitability of spray-runoff soil systems for treatment of feedlot runoff. To development preliminary design criteria and wastewater loading rates for treatment of runoff with a spray-runoff soil system. To demonstrate treatment achieved with a well-designed spray-runoff system.

Work Plan: The project will consist of two phases of work: 1. The first phase will encompass a comprehensive research evaluation of the adaptability of the spray-runoff treatment process to the treatment of rainfall runoff from a beef cattle feedlot. Meat Producers, Inc. will emphasize the on-site supervision and operation of the wastewater collection and treatment facilities. Staff from the Robert S. Kerr Water Research Center will guide us in operation of the system and conduct the research evaluation of the system to achieve objective 1 and 2. 2. The second phase will be devoted to demonstration of the system by Meat Producers, Inc.

3.0325, HYDROGRAPH METHOD OF SEWER DESIGN

C.P. YOUNG, Ministry of Transport, *Berks, England, United Kingdom* (002380)

Following the publication of Road Note No. 35 which was written to guide engineers in the use of the R.R.L. hydrograph method of sewer design, the laboratory operated a computer service on a repayment basis and a total of well over 100 drainage schemes for about 60 local authorities and consulting engineers were computed. Experience gained during the operation of the laboratorys computer service showed that the original computer programs needed improvement in order to cope with the much wider range of circumstances that was at first envisuged, and these improvements led to a new method of interpreting the basic hydrograph method. Research is still proceeding at the Meteorological Office into the characteristics of heavy rainstorms, and refinements to the programs are required from time to time to incorporate the results of this research.

3.0328, DEVELOPING NEW USES FOR MILLING RESIDUES
E.G. VALDEZ, U.S. Dept. of the Interior, Bureau of Mines, *Salt Lake City, Utah* 84112

Develop constructive uses for disposal of solid waste materials such as mine wastes, slags, drosses, flue dusts, tailings, and residues generated in chemical and metallurgical processing. Consider production of various metallic or ceramic products, such as refractories, light weight aggregates and possibly conversion of mineral wastes to usable soils.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0329, PHYSICAL PROPERTIES OF THE SOILS OF VIRGINIA
D.F. AMOS, Virginia Polytechnic Institute, Agricultural Experiment Sta., *Blacksburg, Virginia* 24061 (VA-0200055)

OBJECTIVE: Study the physical properties of various soil series of the state and obtain data on the ranges in these properties. Correlate the physical data with field characteristics to provide supporting data to local health directors and other agencies in evaluation of land for sewage disposal and other urban uses. Study the physical properties and their relation to the genesis and morphology of the various soils.

APPROACH: This study of soil physical properties will be in the following areas: Permeability measurements of important soil types of Virginia to include in place measurements of restricting layers and laboratory measurement of hydraulic conductivity. Interelationships of soil characteristics and the seasonal march of the water table in various Virginia soils to include important soils in the Coastal Plains and Piedmont regions. Extent and nature of the shrink-swell properties of Virginia soils, and soil moisture characteristics and related physical properties of the soils of Virginia.

PROGRESS: Substantial progress was made in characterization of 84 soil profiles from 11 counties. Particle size analyses, swelling potential, and liquid, plastic, and shrinkage limits were determined for each profile. Bulk density and moisture desorption data was obtained for 2/3 of these profiles, with additional sampling required to complete the set. Field studies were initiated in Chesterfield County to determine corrosion potential of certain soil. An initial study in Hanover County yielded excellent data on percolation (infiltration) rate by major horizon for selected profiles of the Cecil, Appling, Faceville and Marlboro series. Preliminary work on a technique to measure strength of development of fragipans in Hanover County soils was quite promising.

3.0330, UTILIZATION OF CELLULOSE AND RELATED COMPOUNDS AS NUTRIENTS
R.D. BROWN, Virginia Polytechnic Institute, Agricultural Experiment Sta., *Blacksburg, Virginia* 24061 (VA-0616007)

OBJECTIVE: Clarify current uncertainties regarding the number of enzymes involved in extracellular degradation of cellulose and the individual functions of these enzymes. Conduct comparative studies of the cellulase systems of various representative bacteria and higher fungi in order to arrive at generalizations it is not now possible to formulate. Explore the technical feasibility of applying this new knowledge to practical problems in food and feed processing, waste disposal, textile processing and related operations involving cellulosic materials.

APPROACH: Using highly purified enzyme preparations the function of cellulases acting alone and in concert will be studied using representative fungal and bacterial species.

PROGRESS: Using the Trichoderma viride cellulase as a model, we have further characterized the essential components of this enzyme system in order to more fully understand the cellulolytic process. A 'C(1)' enzyme which attacks hydrocellulase preferentially has been purified 25-fold from culture filtrates of T. viride. This is the highest purity hydrocellulase known to us, and it is homogeneous as determined by rechromatography, ultracentrifugation and polyarylamide disc gel electrophoresis at pH 9.0. It contains carbohydrate and has a molecular weight of about 44,000. Its amino acid composition reveals a high content of acidic and hydroxylated amino acids and the lowest proportion of non-polar amino acids of any enzyme for which we have seen data. There is more than one type of 'C(1)' enzyme present, as revealed both by ion-exchange chromatography and preparative disc gel electrophoresis. The molecular differences between them may be small-- at this point microheterogeneity due to variable carbohydrate content is suspected. Electrofocussing has revealed that some of the 'C(1)' protein is quite acidic with PI 0. Our future work will be directed toward a more complete description of this cellulase system to permit increased precision in the choice or design of cellulases for application to the practical problems of modifying plant foodstuff.

3.0331, MICROBIAL RELEASE OF SOLUBLE PHOSPHATE IN AN ACTIVATED SLUDGE ENVIRONMENT
C.W. RANDALL, Virginia Polytechnic Institute, School of Engineering, *Blacksburg, Virginia* 24061

The proposed research plan involves laboratory investigation directed at evaluating the factors which affect the microbial release of phosphate back to solution after uptake by an activated sludge system has occurred. The primary approach is to evaluate the effect of activated sludge process operational parameters such as dissolved oxygen and ORP levels, rate and duration of aeration, loading conditions, duration of anaerobiosis, etc., on release of soluble phosphate from the activated sludge microorganisms. A second area of investigation is the ability of various chemicals to stimulate or inhibit activated sludge phosphate release.

Parameter evaluation would employ the following methods. 1. Small scale batch-type experiments to study the effect of the various operational parameters individually. 2. Continuous flow experiments to further study the parameters and their combined effect, and to determine the feasibility of process modification.

Investigation of chemical effects will employ the following methods. 1. Batch-type experiments of individual chemical effects. 2. Warburg respirometer studies to determine lasting effects of chemical addition on sludge performance.

Data will be correlated for clarification of the basic mechanisms of soluble phosphate release from activated sludge microorganisms.

3.0333, PILOT PLANT FOR UNDERWATER STORAGE OF COMBINED SEWER OVERFLOW
B.W. DAHL, Amer. Standard Incorporated, *Falls Church, Virginia* 22045

The problem under investigation is to see if combined sewer overflow water can be retained for short periods in flexible underwater storage containers and subsequently returned to the sewer system. A 200,000 gallon pilot plant will be built and operated to demonstrated the practicality of temporary storage in underwater containers. Operation of the pilot plant for a one year period will allow us to evaluate the ability to operate such a plant and assess the related costs.

Overflow from a 20 acre drainage basin is metered and directed to a pumping station. The flow is than pumped to the flexible storage container anchored in the river. After the flow in the sewer subsides the water in the container will be pumped back to the interceptor sewer. A recirculation system in the container will keep the solids in the system in suspension. In conjunction with the operational program chemical and biological tests will be conducted to assess the character of the storm water both before and after storage and be related to the duration of runoff and storage periods. This project is being conducted in Cambridge, Maryland on the Choptank River. This project was started in Fiscal Year 1968 and will be completed in Fiscal Year 1970.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0334, ISOLATION OF LYTIC AGENTS RELATED TO SPHAEROTILUS
D.J. GEASON, Randolph Macon Womans College, Undergraduate School, *Lynchburg, Virginia* 24501

The primary purpose of this research problem is the isolation and identification of those factors which are responsible for the sudden and dramatic disappearance of the bulking effect caused by Sphaerotilus in activated sludge in sewage treatment plants.

The importance of Sphaerotilus in filamentous bulking can be evaluated using fluorescent antibody techniques which serve to distinguish these organisms from other filamentous organisms with which they may be confused such as Bacillus cereus var. mycoides and Geotrichum candidum.

In those cases where Sphaerotilus is considered to be the cause of bulking, an attempt is being made to determine the conditions under which they are likely to become the dominant organism, and to identify the physical factors and natural predators which may lead to a sudden disappearance of the bulking effect.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0335, UTILIZATION OF FOOD PROCESSING PLANT EFFLUENTS AND THEIR EFFECTS ON SOILS AND CROPS
G.A. PEARSON, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Norfolk, Virginia* 23501 (SWC-027-ANOR-3)

OBJECTIVE: Investigate the utilization and/or disposal of food processing plant effluents and their effects on soils and crops.

APPROACH: Samples of effluents are analyzed for chemical composition. Soil and plant samples are analyzed to evaluate the effects of effluents on the chemical and physical properties of the soil and on the physiological tolerance of the crops.

PROGRESS.

SUPPORTED BY U.S. Dept. of Agriculture

3.0336, ECONOMIC OPTIMIZATION OF SECONDARY TREATMENT AND DETERMINATION OF LOAD TO CONTROL BIOLOGICAL GROWTHS IN A STREAM
H. AMBERG, Crown Zellerbach Corporation, *Camas, Washington* 98607

This project will seek to determine the costs of mechanically aerated lagoon treatment of pulp mill and paper mill wastes by examining in detail the comparison of retention time, aerated lagoon depth, basin configuration, recycle and parallel versus series operation of tow lagoons. Information will also be obtained concerning treatment achieved by multiple lower hp surface aerators compared to two high hp units. Further, the project will, by use of test streams, seek to determine the degree of treatment needed to prevent slime growth in the receiving stream.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

3.0337, COMMUNITY CAGE HOUSING OF LAYING CHICKENS
R.S. HANSEN, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01343)

OBJECTIVE: Develop efficient designs of community cages, including feeders, watering systems, nests and other features. Determine optimum space allowances in community cages, including floor space, feeder space and watering space per hen. Develop shelters suitable for community caged layers in moderate to cool climates. Develop operating methods suitable for community cage housing of layers with emphasis on such problems as cannibalism control, sanitary measures to aid fly control, and efficient operating routines.

APPROACH: Mature pullets will be housed in community cages, generally 3' x 5'; wirepens, larger than 3' x 5'; individual cages, and 5 or 6 bird cages. The design of community cages and wire-pens will be varied in such features as feeders, watering systems, roll-away nests, perches, etc. Criteria used to evaluate results will include egg production, body weight, egg cleanliness and quality, cannibalism and operating efficiency. Cage shelter ventilation, manure removal, fly control and similar management practices will be studied.

PROGRESS: The study of the cause and cure of avian hysteria was continued. Pullets of a strain of chickens with a known nervous temperment were housed in 3' x 5' cages. In a factorial experiment population densities were 20, 30 and 40 hens per cage; blue and white incandescent light was used; a lay ration was compared with the same ration with 50 grams of niacin per ton added. The onset of hysteria was hastened and incidence increased as population density increased. Hysteria occurred under both ligts but was more severe under blue light. Changing from blue to white light alleviated hysteria. Removing the claws near the foot stopped all but one case of hysteria among hens continously under white light. Niacin seemed to delay but did not prevent hysteria.

SUPPORTED BY Washington State Government - Olympia

3.0338, LAGOONS FOR DAIRY FARMS
J. ROBERTS, Washington State University, Agricultural Experiment Sta., *Pullman, Washington* 99163 (WNP01720)

OBJECTIVE: Study bacteriological factors involved in breakdown of cow manure and methods of speeding up bacterial action and management factors, including costs, labor, and water requirements so that design criteria may be developed and made available.

APPROACH: The study as designed will include a comparison of effectiveness of three-stage process with recirculation of two different waste-municipal wastes, and dairy wastes consisting of excreta from dairy cows. Facilities have already been constructed and they are now in operation at city disposal plant.

PROGRESS: The field sprinkler system now takes fluid manure from the storage pond so that the lagoons have less loading and hopefully may function better. The lagoon system is studied by D. Proctor, Sanitary Engineering. The system carrying fluid manure to field plots is giving experience in a new project for which we expect to request funds in 1970. Three circular plots (one sprinkler setting being a plot) were loaded with varying loads of solids. Prior to such loading, shallow and deep soil samples were taken by the Department of Agronomy. Subsequent sampling will study nitrates and nitrate movement. Future WSU research on manure disposal will likely emphasize land (soil) as a receiver, with major emphasis in western Washington locations. Personnel from the Department of Animal Sciences, Agricultural Engineering, Agronomy and Agricultural Economics are planning the work.

3. SOLID WASTE MANAGEMENT

SUPPORTED BY Washington State Government - Olympia

3.0339, TREATMENT AND DISPOSAL OF CONDENSATE WASTES FROM HIGH LEVEL WASTE SOLIDIFICATION PROCESSES
A. PLATT, Battelle Memorial Institute, *Richland, Washington* 99352

A number of low and intermediate level waste side streams result from processes now being developed for the solidification of power reactor fuel reprocessing wastes. These side streams are characterized by low volume, high acid or salt content, and significant levels of radioisotopes, particularly those which exhibit high vapor pressures at the elevated temperatures involved in solidification. This program involves development of techniques for treatment and disposal of these waste side streams.

A number of concepts including precipitation, fractional distillation, scavenging, and crystallization have been evaluated, present emphasis is being placed on sulfate distallation and incorporation of residue in asphalt. Studies will be extended to actual waste streams when they become available in the near future from a current demonstration of waste solidification. The program was initiated in FY'66 and was completed in FY'69.

SUPPORTED BY U.S. Atomic Energy Commission

3.0340, TAILINGS DISPOSAL SYSTEM (EFFECT OF DAM DESIGN ON/EFFLUENT QUALITY, SUBSTRATA STUDIES, SURFACE & SUBSURFACE DISPOSAL)
C.D. KEALY, U.S. Dept. of the Interior, Bureau of Mines, *Spokane, Washington* 99201

Purpose: To study, define, analyze, and develop solutions for problems associated with the disposal of waste products from the mining of large, low-grade ore deposits.

Problems associated with the surface and underground disposal of tailing will be defined and solutions developed with particular emphasis on stope stability, stabilization, effect of topographic conditions, underground support requirements, and effect on surface or underground water (contamination). The mining of a large, low-grade ore deposits will only be possible through the handling of large amounts of material; and, in time, the processing of this material to obtain mineral values will result in large quantities of waste products which have to be disposed of in a manner consistent with the most efficient land utilization.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0341, UTILIZATION OF SOLID WASTES FROM THE COMBUSTION AND MINING OF COAL
D.W. GILLMORE, U.S. Dept. of the Interior, Bureau of Mines, *Morgantown, West Virginia*

Purpose: Develop and evaluate used for solid wastes from coal mining and combustion. Part of the program concerns the disposal of fly ash on surface mine spoil. This dumping method provides for disposal of large quantities of fly ash, aids reclamation, and encourages establishment of vegetative cover on highly acid spoils. The program has been extended to include the use of fly ash for reclaiming unsightly coal mine refuse deposits.

Sintered and raw fly ash are being tested as soil conditioners and sources of trace nutrients. Sintered fly ash is also being evaluated in laboratory and field trials as a skid-resistant agent when incorporated in automobile tires.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0342, DISPOSAL AND UTILIZATION OF DAIRY AND POULTRY MANURES BY LAND APPLICATION
A.D. LONGHOUSE, West Va. University, Agricultural Experiment Sta., *Morgantown, West Virginia* 26506 (WVA00210)

OBJECTIVE: Develop and evaluate disposal and utilization systems for land application of treated and untread dairy and poultry manure that will minimize the pollution of water, soil and air.

APPROACH: Carry out the regional objectives, this station will confine its research programs to the disposal and utilization of manures from poultry in cages. Specifically, systems will be developed to reduce moisture content soon after defecation to prevent development of obnoxious gases, reduce weight (and volume) and control flies. Evaluations will be made to determine the usefulness of the product in respect to land application (physical, chemical and biological properties); the characteristics of reconstituted products and the economic feasibility of the system(s).

PROGRESS: Designed and built basic transport machine adapted to gutter operation under poultry cages. Machine will stir, aerate and remove manure collected in gutter. Two samples of poultry droppings which were analyzed contained 833 million aerobic bacteria and 1.8 billion aerobic nonspore-formers, 115 thousand spore-formers; one billion aerobic nonspore-formers, and 406 thousand aerobic spore- formers. Samples contained 72.4% moisture; 27.6% dry matter; 24.7% volatile matter; and 75.3% ash. Typical five day biological oxygen demand analysis showed 370 mg/L, whereas raw domestic sewage averages about 250 mg/L. Preliminary studies involving the addition of a multiple microbiological culture to the feces in the manure pits, in a cage operation, demonstrated a reduction in moisture content and reduced weight of manure. Studies are planned to determine whether protein breakdown is the source of odor in droppings and, if so, how to overcome odor production.

SUPPORTED BY U.S. Dept. of Agriculture

3.0343, BIOLOGICAL TREATMENT OF SPENT VEGETABLE TANNINS
W.A. SACK, West Va. University, Water Research Institute, *Morgantown, West Virginia* 26506

The overall objective of the proposed study is to determine the feasibility of biological treatment of spent vegetable tannins and other color-producing substances in vegetable tan-house waste. Specific objectives are to: Study the kinetics of adsorption of the tannins on biological sludge; determine what part of the complex tannin extract is biodegradable by an adapted culture, and if degradation will proceed to a point of significant color reduction; study the effect of supplemental carbon sources on the extent and rate of oxidation; obtain data on sludge settleability, required detention times, allowable waste strength, and sludge concentration that may be useful in design of an oxidation ditch for treatment of tannery waste. The investigation will be a bench-scale study using spent vegetable tans containing both condensed and hydrolyzable tannins. A mixed culture developed from a domestic- waste investigation is designed to supply basic information on the adsorption and biodegradation of tans that will be useful in design of a pilot or full-scale unit. The study is directed toward the oxidation- ditch method of treatment.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

3.0344, IMPROVED MARKETING PRACTICES AND MARKETS FOR LUMBER AND OTHER MANUFACTURED PRODUCTS OF EASTERN HARDWOODS
D.G. CUPPETT, U.S. Dept. of Agriculture, N.E. Forest Experiment Station, *Princeton, West Virginia* 24740 (NE4303)

OBJECTIVE: Improve processing, distribution, and use of lumber veneer, and other primary manufactured products with emphasis on low quality hardwoods and little-used eastern softwoods.

APPROACH: Study effects of mill size, layout, equipment, product mix, and distribution methods on cost of producing and marketing sawmill products. Evaluate systems for improving marketability of primary manufactures. Study factors affecting value, utility and use to better meet consumer demand and expand markets for sawmill and veneer mill products.

PROGRESS: Our research concentrated on important aspects of two areas of national concern: Environmental pollution control: Much of the bark residue from wood industry plants is disposed of by burning or dumping, practices that more and more states are severely limiting because of the resulting pollution. Therefore, we began research to expand markets for bark and bark products, and thus eliminate the need for burning or dump-

ing. Results of this work to date show that bark- mulch products have the greatest immediate potential; large volume markets are essential to make bark-mulch production and marketing generally economical; and large-scale application of bark mulch to highway banks, strip-mine spoils, and similar areas necessitates the use of power mulchers. Our studies showed that either raw or processed bark can be applied successfully by the power mulchers now available for other mulch products. New or expanded sources of wood products for home building. Eastern spruce and hemlock are potential sources for increased supplies of lumber and plywood. In one study of the market potential for eastern spruce plywood, 89 percent of the architects and 83 percent of the contractors indicated they would use eastern spruce plywood, provided it is properly grade-stamped. Both groups indicated that eastern spruce plywood has favorable potential for both structural and decorative uses in housing construction.

SUPPORTED BY U.S. Dept. of Agriculture

3.0345, A STUDY OF LAND DISPOSAL OF SPENT SULFITE LIQUOR AT BADGER PAPER MILLS, INC., PESHTIGO, WISCONSIN

T.A. CALABRESA, State Dept. of Nat. Resources, *Madison, Wisconsin* 53701

This cooperative project provides for the determination of the extent of movement of spent sulfite liquor both in depth and laterally from the ground surface disposal areas. This project hopefully will result in determinations of: 1. The influence that the bedrock configuration has on the subsurface movement of the waste sulfite liquor. 2. The effect limerock in the area has, if any, in neutralizing some of the acidity of the waste. 3. The potentiometric distribution of the sulfite liquor both vertically and horizontally in the surficial deposits above the limerock in the vicinity of the disposal sites. 4. The aquifer characteristics both in the unconsolidated and rock aquifers. 5. The quantity of the waste reaching the river. 6. Whether the Badger Paper Mills, Inc., shall abandon the present disposal method in favor of some other treatment method insofar as the Peshtigo River is concerned. 7. Whether such land disposal practice of this type or other strong industrial waste can be safely permitted under similar geological conditions.

SUPPORTED BY Wisconsin State Government - Madison

3.0346 PULP AND PAPER ENGINEERING SYSTEMS

W.F. CARR, U.S. Dept. of Agriculture, Forest Products Laboratory, *Madison, Wisconsin* 53705 (FPL3307)

OBJECTIVE: Develop basic improvements in the unit processes of pulp and paper manufacture; increase the utilization of logging and manufacturing residues and urban fibrous waste and associated solid waste; design and maintain pilot plant facilities for demonstration of effective process development.

APPROACH: Investigate various tree segments to establish pulping and papermaking properties. Investigate relative economics of bark separation systems with determination of tolerable bark levels in paper grades. Develop systems for the reuse of waste fibers with resulting products which could be utilized. Study factors which affect efficiency of separation of usable and undesirable fractions to establish interrelationships.

PROGRESS: Exploratory investigations have been completed to determine possible target systems for recovering wood and wood fiber products from municipal solid waste. This investigation has determined feasible systems and thus approaches for undertaking studies for obtaining information and procedures leading to an effective solution to the solid waste disposal problem. The selection of desirable wood fiber products that should be investigated as possible products from municipal solid waste was completed. Exploratory contacts with other interested groups within Federal and City governments were undertaken to determine if a combined effort in the utilization of municipal solid waste could be incorporated into a common purpose and hopefully a common system for an effective solution to the problem. To undertake studies in improving the utilization of all segments of the tree for wood fiber needs and the related area of bark utilization and economics in wood harvesting which would lead to an effective solution, a comprehensive analysis within the framework of the larger problem area of increased tree utilization was completed.

SUPPORTED BY U.S. Dept. of Agriculture

3.0347, PHOSPHORUS REMOVAL BY TRICKLING FILTER SYSTEMS

W.C. BOYLE, Univ. of Wisconsin, School of Engineering, *Madison, Wisconsin*

The objective of this investigation is (1) to determine the present performance of trickling filters in the State of Wisconsin with respect to phosphorus removal and (2) to study in detail the factors influencing the phosphorus removal characteristics of trickling filters.

The first phase of this study consists of a field survey of ten existing plants in the state over a one and one-half year period. Composite samples of waste water will be collected weekly and BOD, solids, pH, and total and soluble phosphorus determinations will be made. Special studies on several selected filters will be made during this period of time to ascertain the influence of digester supernatant return, organic loading, temperature and media characteristics on phosphorus removal.

The second phase of the study is being conducted in four-twelve foot deep pilot filters each with a cross-sectional area of four square feet. These plants will be studied in accordance with a factorial design to determine the effects of hydraulic load, depth, organic load, recirculation ratios and temperature on phosphorus removal. Special studies will be conducted on the filter slimes during this phase of the study. The study is being conducted at the Nine Springs Sewage Treatment Plant in Madison, Wisconsin.

Due to setbacks in material shipment, this study will not be completed before the winter of 1970.

SUPPORTED BY Wisconsin State Government - Madison

3.0348, ANIMAL WASTE MANAGEMENT WITH POLLUTION CONTROL

J. CONVERSE, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS05008-6008)

OBJECTIVE: Characterization of physical, chemical and biological properties of livestock and poultry wastes; Improvement in management systems with regard to handling, treatment and disposition of wastes.

APPROACH: Of immediate interest are treatment methods of digestion and lagooning including a detailed study of basic properties of wastes. Effects of dietary variables on quantity, chemical composition and microbial content of poultry excreta during growth and egg production will be investigated. Dietary variables will include amino-acid protein- energy balance, cellulose and lignin level, mineral level, antibiotics, anti-microbial compounds, laxatives, and water intake. Decomposition of excreta will be studied under both aerobic and anaerobic conditions.

PROGRESS: Three year averages on 0.01 acre plots show more runoff and nutrient losses from those receiving no manure than those summer manured. Greatest difference in runoff occurred during summer with unmanured plots losing nearly twice as much runoff as the average of all others. This condition has become worse with each succeeding year. On an annual basis unmanured plots lost 14% more N and 48% more P than summer manured plots. Winter manured plots have lost 3 times as much N, 2.5 times as much P and 4 times as much K as the average of all other plots. These studies indicate the need for over-winter storage of manure to preserve the nutrients and minimize stream pollution potential. They also show the need for manure as a soil conditioner and to maintain fertility. The bacteriological flora of fresh bovine feces and of anaerobically stored manure from the Marshfield Station and the ABS lagoon sludge has been compared and important groups of facultative and obligate anaerobes identified. Growing in stored manure were urea fermenters and fatty acid utilizers. They are staphylococci. Several new properties for S. saprophyticus and S. epidermidis were recognized and related to manure storage.

3. SOLID WASTE MANAGEMENT

SUPPORTED BY U.S. Dept. of Agriculture

3.0349, APPRAISAL OF ADJUSTMENTS IN WISCONSIN AND OTHER LAKE STATES DAIRY FARMING
N.D. KIMBALL, Univ. of Wisconsin, U.S.D.A. Farm Prod. Econ. Div., *Madison, Wisconsin* 53706 (FE9-15-52-01)

OBJECTIVE: Construct a research background for development and appraisal of farm programs, and provide information needed by Wisconsin and other Lake States dairy farmers in making adjustments in their farming systems during the next few years.

APPROACH: Appraise the situation in dairy areas as to major adjustment problems, resource situations and available alternatives. Select and evaluate alternative production practices and estimate costs and output for alternative systems, taking into account prices of farm products and services. Estimate the changes in production, costs, and returns as a basis for outlining combinations that will lower costs and increase returns. Use farm budgeting and linear programming. Study the area and interregional implications of the adjustments and the effect of changes in transportation costs and provisions of milk market orders on production and distribution patterns.

PROGRESS: A manuscript entitled Economic Evaluation of Forage Handling Systems was revised and submitted for publication. The results of a study on liquid manure handling are being prepared for publication. Four types of systems were surveyed: free-stall barns with (1) all excrement put through the liquid system, and (2) part of the yard manure handled conventionally; conventional barns with (3) all liquid, and (4) part conventional. Farms surveyed were much above average in size with 85 cows and a gross income of over $50,000. The study showed that the largest cost item was the storage tank with a marginal cost of from 40 to 70 cents per cow-day of capacity. Free-stall systems had the highest costs because of the needed reinforced tank lid and more labor and tractor hours were required. The stachion barn system's cost were lower than free-stall systems. However, the freestall barn, all liquid system was second least cost when the value of the manure recovered was considered. Equating fertilizer value with costs of handling indicated the following herd sized to pay for the system was second least cost when the value of the manure recovered was considered. Equating fertilizer value with costs of handling indicated the following herd sizes to pay for the system when storage was for 120 days: free-stall, all liquid, 58 cows; part conventional, 80 cows; stanchion barn, all liquid, 44 cows; and part conventional, 67 cows.

SUPPORTED BY U.S. Dept. of Agriculture

3.0350, RETENTION OF NUTRIENTS AND OTHER POLLUTANTS IN SEWAGE BY SOILS
L.B. POLKOWSKI, Univ. of Wisconsin, School of Engineering, *Madison, Wisconsin*

The objective of this study is to determine the ability of a given soil type in retaining or removing nutrients and other indicators of pollution from the effluent of a septic tank-soil absorption system under actual field conditions. The site of this investigation is the Wisconsin Heights High School near Mazomanie, Wisconsin. After determining the direction of groundwater travel, 24 driven point wells were installed in the vicinity of the tile absorption field. The soil consists of a silty clay loam changing to sandy loam underlain by outwash sand and gravel.

Groundwater samples were taken from the wells weekly from April September (1967) and on a bi-weekly schedule thereafter. Analyses were made for BOD, chlorides, detergents (MBAS), nitrogen, phosphorous and coliforms.

SUPPORTED BY Wisconsin State Government - Madison

3.0351, CHEMICAL PULPING AND BLEACHING
N. SANYER, Univ. of Wisconsin, U.S.D.A. Forest Products Lab., *Madison, Wisconsin* 53706 (FPL3301)

OBJECTIVE: Develop improved pulping process for more complete utilization of all wood species as fiber or chemical raw material, while effectively reducing air and stream pollution.

APPROACH: Study pulping with oxidizing and reducing agents, polysaccharide stabilization in alkali, chemical and physical treatment of pulp for improving their strength and optical properties, recovery of cooking chemicals and byproducts, stabilizing color and strength of chemimechanical pulps toward light and aging, bleaching reactions with chemical recovery, post-delignification in digester for partial bleaching while preserving fiber strength.

PROGRESS: Wood delignification with oxygen compounds in mild alkali was investigated further for developing new pulping and bleaching processes where the sulfur compounds and attendant air pollution associated with the existing chemical pulping methods will be eliminated. In a series of model reactions, the oxidation of cellobiose with molecular oxygen and peroxygen compounds was shown to improve its alkali stability. In the course of delignification, however, wood polysaccharides were oxidatively depolymerized. Certain reaction schemes are being evaluated for preventing this and for further practical development of the method.

SUPPORTED BY U.S. Dept. of Agriculture

3.0352, WINTER STORAGE OF DAIRY WASTES IN NORTHERN CLIMATES
S.A. WITZEL, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (901-031-B616)

OBJECTIVE: Develop technology for the winter storage of dairy manures that will lead to a reduction of their pollution potential.

APPROACH: Evaluate all aspects of cold climate storage of dairy manures. The methods to be studied include stacking of the solid wastes, tank storage of wastes in liquid or slurry form, deep anaerobic lagoons, loose housing manure pack and others that may seem applicable. An analysis will be made of the wastes going in and coming out of storage to provide a basis for evaluating the reduction or altering of pollution potential as affected by the chemical and physical changes which occur in the specific storage methods. Studies will also be made of the handling methods and management requirements for installing the specific storage method into the overall waste management system.

PROGRESS: Studies were initiated on over winter storage of dairy cattle waste with 5 varying types of barns and manure storage systems. A 10,000 cubic foot storage structure at Ashland Station was filled in 125 days, a solid production including bedding of 3 1/4 cubic feet per cow per day. Seepage from the stack yielded about 2 gallons per cow per day. Minimal freezing occurred in the stack; some odor was detected under certain weather conditions. Total waste production from 2 cows for a 3-day period each month, solid and liquid wastes plus bedding, averaged slightly over 3 cubic feet per cow per day. Manure scraped from an uninsulated free stall barn into a 3000 gallon underground tank was pumped monthly under the ice into the lagoon at Marshfield Station. Frozen manure and yard scrapings containing snow were stacked on the concrete slab to prevent freezing in the tank. Little odor was detected from the lagoon. At Arlington Station, a loose housing system with manure pack storage of 180 days is used. Droppings from the feeding barn, paved lot, and manure pack were collected daily when weather permitted. They amounted to 110 lbs. per cow per day, a major portion of the manure production. Liquid manure systems were studied on two private farms. In one case, cows were confined to the barn, the liquid manure storage of 203 cubic feet per cow filled in 2 1/2 months. On the second farm when weather permits the free stall and lot are scraped into the underground tank. Odors in either case have not been typically offensive. Chemical analysis of the wastes have not been completed.

SUPPORTED BY U.S. Dept. of Agriculture

3.0353, SEWAGE PHOSPHORUS REMOVAL BY AN ACTIVATED SLUDGE PLANT
L.A. ERNEST, Milwaukee Sewage Commission, *Milwaukee, Wisconsin* 53201

The objectives of this project are to demonstrate the optimization of activated sludge process parameters for maximum sewage total phosphorus removal, to determine if a correlation

exists between activated sludge dehydrogenase activity and phosphorus removal and evaluation of process parameter effects on phosphorus level in an aeration tank. An appropriate sampling and analysis program will be initiated to evaluate the effects of process variations.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

3.0354, A MATHEMATICAL MODEL FOR THE FINAL CLARIFIER OF AN ACTIVATED SLUDGE PROCESS
W.J. KATZ, Rex Chainbelt Incorporated, *Milwaukee, Wisconsin* 53201

Develop a mathematical model expressed in computer format which will enable the prediction, with a high degree of reliability, the quantity and quality of the effluent and underflow of a final clarifier in an activated sludge treatment system as a function of the mixed liquor flow rate and characteristics.

The subsidence characteristics of activated sludge relates to the clarification and thickening properties of the sludge. Measurements such as sedimentation rates, suspended solids concentration, volatile suspended solids concentration, zeta potential, etc. are required to identify the performance of the clarifier. The relationship of these basic parameters and other variables with respect to the performance of the final clarifier is what the mathematical model must express. It is the objective of this proposal project to measure and evaluate those parameters which have interrelationships to each other that influence the operational performance of the clarifier, and to relate them, if possible, in terms or parameters which are normally available to the consulting engineer concerned with the basic design of the final clarifier.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

3.0355, LABORATORY SCALE FEASIBILITY STUDY OF USING REVERSE OSMOSIS TO CONCENTRATE PRE-TREATED DOMESTIC SEWAGE
D.G. MASON, Rex Chainbelt Incorporated, *Milwaukee, Wisconsin* 53201

The objective of the proposed project is to establish, through a laboratory scale study, the feasibility of utilizing reverse osmosis (R-O) as a means of concentrating domestic sewage for subsequent treatment by the activated sludge process. It is anticipated that successful completion of this objective will make possible a substantial reduction in the size of the equipment normally required for treatment of such flows, thereby reducing both capital and operating costs. In addition, the R-O process will produce a product water stream which, following disinfection, may be returned directly to municipal drinking water supplies.

The project will be conducted over a twelve (12) month period, and will comprise three major determinations: 1) establishment of the pre-treatment steps required to allow R-O to function effectively as a subsequent process; 2) determination of the amenability of the R-O waste concentrate stream to activiated sludge secondary treatment; and, 3) establishment of the R-O product water stream quality as meeting Public Health Service Drinking Water Standards. Preliminary cost information will also be developed to determine the engineering feasibility of the overall concept.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P.

3.0356, FECAL COLIFORM DIEOFF IN SEWAGE TREATMENT LAGOONS
K.T. CRABTREE, Univ. of Wisconsin, Undergraduate School, *Wausau, Wisconsin* 54401

Fecal coliform dieoff in domestic sewage lagoons. The primary emphasis is enumeration of the organisms in domestic raw sewage; primary and secondary effluents from the lagoons to determine the necessity of chlorination or some other means of disinfecting the effluents before discharge into receiving lands, streams, rivers and lakes. Various physical and chemical factors on the effects of coliform and fecal coliform counts are investigated. They are: retention time of the ponds, flow B.O.D., temperature and seasonal variation, occurrence of algal bloom, massive emergence of zoo-plankton, and of chlorination. Concomitant investigations include re-evaluation of media designed for detection of coliform and fecal coliform, effect of storage time for various sewage oriented samples, effect of incubation temperature (25, 37, 44.5 degrees C) on the coliform and fecal coliform counts. The project likewise includes enumeration of fecal streptococci and Pseudomonas aeruginosa which are considered as potential health hazards of man and animals as supplementary indices of fecal pollution. The project is jointly carried out with Prof. William C. Boyle, Dept. of Civil Engineering, and his graduate students. They are to investigate lagoons in the southern area of Wisconsin while our group is to cover central and northern Wisconsin. The project was initiated on July, 1969 and will be completed January, 1971.

SUPPORTED BY Wisconsin State Government - Madison

3.0357, STUDY OF WASTE DISPOSAL PROBLEMS
S.S. TIHEN, U.S. Dept. of the Interior, Bureau of Mines, *Laramie, Wyoming*

The purpose of this project is to study problems associated with disposal of spent shale and to devise methods for treating retorting process waters to remove contaminants or reduce them to harmless levels. Methods of treating spent shale dumps to reduce wind and water erosion and to reduce their deleterious effects on environment and ecology and methods of preventing possible contaminations of water sources by rainfall and snowfall leaching of spent shale dumps will be developed.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

E. RECYLING AND UTILIZATION

Byproduct Development, Reprocessing, Conservation of Raw Materials, and Other Related Studies.

3.0358, BROILER MANAGEMENT
G.J. COTTIER, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA-10-0305)

OBJECTIVE: Study re-use of litter for broilers, fertilizer value of broiler house litter, and control of Gumboro disease. Collect data on 33 pens on litter study, 45 pens on Gumboro disease, and 90 samples of broiler house manure analyzed for nitrogen, phosphorus and potassium.

APPROACH: Continue work on broiler management.

PROGRESS: A total of 48 pens of broilers were marketed in the reuse litter study. The number of broods raised on the same litter varied from one through three. Growth, feed efficiency, and mortality were similar regardless of the number of times the litter was used. A total of 51 samples of litter were analyzed for nitrogen, phosphorous and potassium. A study on the effect of aflatoxin on different breeds and strains of chickens was conducted using 7 breeds, 2 crossbreeds, and 5 strain crosses. Criteria used were weight gain, shank color, mortality, organ size and pathological changes.

SUPPORTED BY Alabama State Government

3.0359, CONSERVATION OF RESOURCES IN MUNICIPAL WASTE
K.C. SANDERSON, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA-09-0406)

OBJECTIVE: Determine means of conserving and utilizing processed garbage as: a mulch for ornamental plants, a seed coating or slurry for seeds and cuttings used to establish plants on the highway and a soil additive in the production of woody ornamental and floricultural crops.

APPROACH: Processed garbage will be compared with recommended mulches for roadside use. The effect of the mulches on soil moisture and temperature and plant growth will be determined. As aqueous slurry of processed garbage, wood cellulose, and seeds or root cuttings of various woody ornamentals will be sprayed on slopes on the roadside and survival noted. Processed garbage will be compared with standard organic soil amendments in various soil mixtures used in the production of ornamentals. The effect of processed garbage on the pH, water, retention, nutrition and plant growth will be determined.

3. SOLID WASTE MANAGEMENT

PROGRESS: Plants grown in soils amended with processed garbage yielded a reduction in height and fresh weight of chrysanthemums, dry weight of geranium and leaf-size and dry weight of gloxinnias and an increase in flowerhead length of snapdragons and plant height and flower number of Easter lilies. Chrysanthemum grown in garbage-amended media contained twice the recommended optimum range for boron. The manganese content of plants grown in garbage-amended media was at a toxic level for certain varities. Plants grown in garbage-amended media were high in potassium and zinc. Garbage did not seem to exert any adverse effect on the germination of 15 species of plants. Boron toxicity ma[illegible] ive[illegible] arred in radish and lima bean. Growing in garbage or g[illegible]age [illegible]nded media reduced the dry weight of kale, lima bean[illegible]di[illegible]nd sunflower. Compared with sawdust and pine straw, [illegible]to[illegible]ed garbage mulch gave comparable growth results [illegible]rysanthemums and petunias. Chrysanthemums grown [illegible]ocessed garbage from various sources exhibited stunting [illegible]me products. Processed garbage was combined with a nutri[illegible] chemical additions and recomposted to increase fertilit[illegible] reduce pH, soluble salts and phytotoxicity. Chrysanthem[illegible] grown in recomposted garbage-amended media did not exhi[illegible] phytotoxicity or growth reduction observed with unrecom[illegible] garbage-amended media.

3.0360, SOLID WASTE RESEARCH UTILIZATION OF WASTE GLASS FROM MUNICIPAL REFUSE

M.E. TYRRELL, U.S. Dept. of the Interior, Bureau of Mines, *University, Alabama* 35486

Research in this project is directed to the utilization of waste glass recovered from municipal wastes either before or after incineration. Glass fractions used in the research are obtained from the solids waste reclamation continuous operating experimental plant at the Bureau's College Park Metallurgy Research Center. The principal areas of potential use of the glass to be investigated are (1) structural units, (2) thermal insulating materials, (3) glass beads, and (4) glaze frits. Emphasis of the work will be (a) to investigate mixtures of waste glass and additives and furnacing techniques required for making marketable glass wool, (b) to develop furnacing and cleaning techniques for converting waste glass into high quality glass bead products, and (c) investigations to determine the character and quality of structural block and other units made from ceramic bonded waste glass.

3.0361, DEVELOPMENT OF PROCESSES FOR IMPROVED FEEDS FROM AGRICULTURAL WASTES

H.G. WALKER, U.S. Dept. of Agriculture, Western Utilization Res. Div., *Albany, California* 94710 (W1-2-75)

OBJECTIVE: Convert lignified agricultural residues from vegetable and animal sources into useful animal feeds, thereby reducing environmental pollution from these waste materials.

APPROACH: Process lignified agricultural wastes to increase their cellulose digestibility. Study acidic, basic, and oxidative treatments under varying conditions of temperature and pressure of grass and cereal straws, other vegetable wastes and animal wastes. Study physical stresses like shear, compaction, dehydration and the like. Evaluate effects of processing by enzymatic in vitro methods. On promising treatments, evaluate by in vivo tests through cooperative research with other ARS divisions, experiment stations and industry groups.

PROGRESS:

SUPPORTED BY U.S. Dept. of Agriculture

3.0362, DISPOSAL OF BRINE EFFLUENTS BY CONVERSION TO BY-PRODUCTS

R.R. GRINSTEAD, Dow Chemical Company, *Walnut Creek, California* 94598

This project will examine the application of solvent extraction methods to the separation and concentration of desalination brines to produce products which can be disposed of in normal industrial channels. Such products will include sodium chloride, sodium carbonate, magnesium and calcium carbonates, sodium and ammonium sulfates, and chlorine and caustic soda (from electrolysis of sodium chloride brine).

A dual extraction system will be studied, and will be analogous to the Desal ion exchange process for desalinating brackish water. The initial step would be based on the use of amine systems to convert anionic constituents of the brine to bicarbonates, and the second step will utilize acidic extractants to acidify the bicarbones to carbon dioxide. Among the by-products will be sodium carbonate, which can be used to remove divalent cations from the brine feed or from the original brackish water, ahead of the desalination step. In the latter case, the softened feed water would allow a greater recovery of water in the desalination step.

The rationale of using extraction methods in this application rests on the ability of extraction processes to treat and produce stronger salt solutions than ion exchange of methods, since problems of dilution due to mixing of aqueous phases are eliminated.

SUPPORTED BY U.S. Dept. of Interior - Off. Saline Wat[illegible]

3.0363, NEW AND IMPROVED PRODUCTS FROM WESTERN SOFTWOODS

L.A. MUELLER, Colorado State University, U.S.D.A. Rocky Mtn. For. Sta., *Fort Collins, Colorado* 80521 (RM3201)

OBJECTIVE: Contribute to better forest management, increased effective timber supply, and regional economic development through more efficient utilization. Develop new and improved products using western softwood timbers. Improve utilization of Rocky Mountain and Southwestern forests.

APPROACH: Develop new or improved products that will meet user requirements, match timber characteristics with user needs, and result in higher value production from available softwood timbers. New or improved products for lower common grades of ponderosa pine in the Southwest is first priority. Second is new products for other Rocky Mountain species. Third is reducing waste in woods and mills and better use of residues. Comprehensive work from product concept through pilot plant tests requires integrated marketing studies.

PROGRESS: Ponderosa pine stumpwood potential naval store source. Sample yields 31 percent benzene-soluble extractives, exceeding Southern pine. Extractives unique in that they contain about 6 percent longifolence, only domestic source and currently priced at $1,180 to $1,230 per metric ton. Engelmann spruce possible new fence post source. Successful treatment by modified double-diffusion process offers potential of adding species to approved list. Lumber can be overlaid by roll-laminating process at speeds up to 180-feet per second for $.04 to $.05 per board foot. Open defects severely limit the proportion of the lower grade lumber that can be used. Lower Common grades of Black Hills ponderosa pine lumber as components in laminated decking panels meet strength values of standard decking products. Equilibrium moisture content of laminated beams in service in area, interior and exterior, range between 6 and 8 percent; season of year of no significance. No seasonal variation found in liquid or gas permeability of inland Douglas-fir, Engelmann spruce, or lodgepole pine. Results rule out season of harvest as major cause for variability in drying and treating. Multiproduct inventory system further developed to better recognize and measure the basic stem characteristics and defect features that influence quantity and quality for most primary products.

3.0364, DAIRY CATTLE MANAGEMENT IN URBAN PROXIMITY

G.F. HAENLEIN, Univ. of Delaware, Agricultural Experiment Sta., *Newark, Delaware* 19711 (DEL00604)

OBJECTIVE: Evaluate feeding, breeding, and milk production procedures suitable to suburban conditions and maintain herd, buildings and equipment as an example of good management practices. Provide for research groups of calves, and cows with the necessary uniformity in age, genetic background and high productive capacity. Assist in training, teaching, and demonstrations for students, 4-H, FFA, and other interested organizations and visitors.

APPROACH: Under closely controlled conditions of management and detailed record keeping, current problems in dairy cattle management are being examined, e.g. milk measuring devices, different feeds, ingredients and feeding procedures, calf raising methods, the effects of management, feed and inheritance upon the composition of milk, particularly the contents of fat, solids-not-fat and protein. In cooperation with other research projects, groups of animals are being selected on the basis of their herd records and maintained e.g. several rumen fistulated cows, spayed heifers, castrated bulls and animals for analyses of blood, milk, excreta, reproductive and other organs. The necessary equipment and apparatus for quantitative feeding, sampling, and collection is designed as the need arises and machined and manufactured in cooperation with the agricultural engineers.

PROGRESS: Research with the dairy herds involved: (1) inheritance of milk proteins by (a) testing for % fat, % SNF and % protein, (b) electrophoretic identification of alpha(s)-casein, beta-casein, beta- lactoglobulin and kappa-casein genetic types for each cow, (c) antigen typing for blood types of each heifer and cow; (2) physiology of abnormal milk secretion by testing 18 cows daily for leucocyte contents, % skim protein, % casein, % whey and freezing point depression; (3) rumen microbiology by maintaining 4 rumen fistulated cows; (4) cooperative milk testing for bacteria contents with a new pilot instrument of the DuPont Company (results showed unexplained inconsistencies not related to standard methods); (5) cooperative project with the Drexel Institute - Philadelphia about utilization of animal solid waste products; (6) the new Environmental Control Large Animal Research Barn was completed and is housing groups of 3 heifers, 12 cows, 12 calves, 12 sheep and 4 horses for metabolism studies.//Extension activities

3.0365, PEAT STUDIES

C.C. CAMERON, U.S. Dept. of the Interior, Geological Survey, *Washington, District of Columbia* 20242

States to which project pertains: Eastern United States with emphasis on West Virginia, Maryland, Pennsylvania, New York and Maine.

Exploration of peat deposits suitable for soil conditioner and horticultural use by field study in ten areas representing major terrane types typical of northeastern United States. Five areas chiefly in New England and along the coast remain to be studied.

Objectives include: discovering physiographic and geologic controls of deposit occurrence and size: determining relation of stratigraphy and ecology to water movement and diagenesis affecting peat quality change: cataloguing major deposits according to new ASTM standards for current agricultural uses and anticipated uses in manufacture of foodstuffs and pollution controls.

Objectives are aimed at facilitating exploration by private industry and at presenting quantitative data obtained on deposit environments to assist others in their ground water, engineering, conservation, land management, and geochemical prospecting studies.

Deposits are measured, traversed, cored, and sampled for pH ASTM peat tests, and semiquantitative spectrographic analyses.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

3.0366, EFFECTS OF GARBAGE COMPOST ON SOIL PROCESSES

C.C. HORTENSTINE, Univ. of Florida, School of Agriculture, *Gainesville, Florida* 32601

Previous research under laboratory conditions showed that composted municipal refuse was an effective agent in preventing nitrification processes in animal manures. In light of current pressure on cattle feedlot operators and dairymen to prevent nitrate entry into surface and ground water supplies, this research was extended to simulated field conditions. Small lysimeters were used in which various rates of compost and cow manure were mixed with soil. A crop was grown in the soil and soil samples and leachates were collected for nitrification studies. Indications to date were that compost above 8 tons/ha applied to Arredondo fine sand prevented nitrification in manure applied at the rate of 40 tons/ha.

Field studies will be extended in an effort to determine the maximum amount of compost that may be applied to soil used for agricultural purposes. Previous research has indicated that Florida soils may be capable of assimulating as much as 200 - 400 tons/ha of compost applied on a yearly basis. However, the long time effects on soil characteristics and plant growth from such large amounts of compost are not clear.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0367, LIME TREATMENT AND IMPLANT REUSE OF AN ACTIVATED SLUDGE PLANT EFFLUENT IN THE CITRUS PROCESSING INDUSTRY

J.W. HAYES, Winter Garden Cit. Prod. Coop., *Winter Garden, Florida* 32787

The objective of this proposal will be to develop operational parameters and conduct an economic evaluation on lime treatment of effluent from a 2 mgd activated sludge system treating citrus wastes and in-plant reuse of the lime treatment effluent. The study will cover lime treatment, with the addition of coagulant aids, and dewatering of sludges by centrifugation for usage in cattle feed preparation. Determination will be made on this system's effectiveness in further reducing BOD, COD, and nutrients found in the activated sludge effluent.

The proposed project intends to demonstrate the effectiveness of lime precipitation on effluent from a 2 mgd activated sludge system treating citrus wastes. The activated sludge system consists of an aeration pond providing from 24 to 36 hours detention time with the overflow being directed into a final clarifier. Operation of the activated sludge system will afford pH control along with nutrient supplementation and sludge recirculation.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

3.0368, SOIL FERTILITY MAINTENANCE WITH FERTILIZERS, CROP RESIDUES, AND ANIMAL WASTES

W.E. ADAMS, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Watkinsville, Georgia* 30677 (SWC-031-BAW-05)

OBJECTIVE: Determine methods of improving the availability of nutrients from fertilizers, crop residues, and animal wastes on Piedmont and slate soils, clay pit spoil; the phytotoxic compounds found during decomposition; the rates at which residues and wastes can be applied without damaging the crop or polluting the ecosystem; the soil and climatic factors which affect the nutrient supply to crops and the efficiency of nutrient use by crops; the influence of fertilizers, crop residues, and animal wastes on crop quality.

APPROACH: Varying rates of inorganic fertilizers, crops residues, and poultry litter will be applied to small plots of fescue, Coastal bermudagrass, and corn; varying tillage methods will be used to dispose of animal wastes on tilled plots. Sintered ceramic candles will be buried at depths to sample ground water. Soil, forage, and crop samples will be analyzed to determine the influence of the fertility and residue treatments on crop quality.

PROGRESS: Investigations were continued at Watkinsville, Georgia to study the interaction of clipping frequency x N-K levels on the quality of Coastal bermudagrass. Total available carbohydrate (TAC) content of roots and forage regrowth were lowest in the spring and highest in the fall. In contrast, the total N (TN) content was reversed. Rhizomes contained considerably more TAC and TN than either stolons or fibrous roots. N rates (200 and 600 lb/acre) had little influence on TN content of roots. However, a wide N:K ratio (6:1) increased the percentage of TN while a narrow N:K ratio (2:1 or 1:1) reduced the TN percentage. The least forage regrowth was associated with the highest N level and the 6-week clipping frequency.

SUPPORTED BY U.S. Dept. of Agriculture

3.0369, USE OF SEWAGE TO PRODUCE ALGAE FOR LIVESTOCK FEED

UNKNOWN, Natl. Botanic Gardens, *Lucknow, Uttar Pradesh, India* (908-034-B706)

OBJECTIVE: Develop methods and equipment for economical production, harvesting handling, processing feeding of sewage-grown algae.

3. SOLID WASTE MANAGEMENT

APPROACH: Collect samples of sewage from towns in Eastern and Central Uttar Pradesh for study of various species of algae, fungi, and bacteria normally growing in sewage liquids under Indian conditions. Evaluate algae for protein content and metabolic efficiency. Grow selected algae in oxidation tanks about 15'x30' x 3' to 5' deep and study factors affecting growth, with particular reference to N,C, P, Mg, K, temperature, and light. Evaluate various harvesting methods, including mechanical, electrical, and chemical, for cost and effectiveness. Study chemical composition of the sewage grown algae for protein, carbohydrate, fat, mineral, and vitamin content. Determine nutritional and feeding qualities (including pathogenic bacteria survival) for farm animals and poultry.

PROGRESS: A survey of algal flora of sewage in relation to physico-chemical characteristics of important towns of Uttar Pradesh was undertaken. It is significant that there is a great degree of similarity in algal and physico-chemical characteristics of the sewage of U.P. towns in spite of the wide range of variation in the density of human population. The nutrients, especially nitrogen and phosphorous, which support rich growth of algae, are present in appreciable quantities. The range of pH is also favorable in most of the towns of which survey was made. These factors are of special significance for the further pilot plant studies in stabilization ponds. Thirty-two species of algae have been recorded. Cyanophycean species dominate over other groups of algae. Experiments were conducted to harvest Microcystis aeruginosa and Selenastrum minutum, which form rich bloom in L.S.G.E.D. oxidation ponds at Lucknow. It was observed that the optimum concentration of flocculants required varied from 100-400 ppm for Microcystis and 300-400 ppm for Selenastrum. Six flocculating agents were tried, out of which commercial potash alum seems to be the cheapest and most effective. The final pH of the flocculating medium is also important for effective precipitation of algae. The aluminum- containing compounds were found to be effective at acidic or more or less neutral pH, whereas iron-containing flocculants were found to be effective at alkaline or slightly acidic pH levels.

SUPPORTED BY U.S. Dept. of Agriculture

3.0370, MULTI-PURPOSE UTILIZATION OF HARDWOOD BARK THROUGH CHEMICAL MODIFICATION

C.A. ECKELMAN, Purdue University, School of Agriculture, *Lafayette, Indiana* 47907

The potential value of bark as an untapped source of raw material is demonstrated by the fact that the forest industries remove and dispose of about 20 million tons of bark annually. Its present disposal creates air and water pollution problems. Much of the effort to utilize bark is waste oriented which means seeking uses without conversion into other forms. It is the purpose of this research to open the way to the transformation of bark into an asset. The knowledge of hardwood barks is very limited; therefore, physical and standard mechanical properties of bark of three selected hardwood species will be evaluated. Improvements in their strength characteristics, binding properties, fire resistance, and water sorption characteristics will then be sought by chemical modification with commercially available compounds. It is essential that these properties be improved, or changed if bark is to be used as the main constituent in products such as building boards and other composite materials for the housing industry, which volume wise may be an enormous outlet for such materials. However, because bark is a complex, non-homogenous, material with properties dependent on wood species, no single approach can be used to solve hardwood bark utilization problems economically. Rather, a multi-purpose approach is needed. The multi-purpose utilization will be carried out in several ways; e.g., the extraction will be removed and used as a source of chemicals and pharmaceuticals, and the remaining fibrous material - after chemical modification - will be used in production of different types of composite materials. Another possibility includes extraction of chemicals, separation of extractive - free bark into two layers, and utilizing the stronger inner layer for structural materials and the weaker outer layer as a filler or an ion exchange medium.

SUPPORTED BY Purdue University - Lafayette, Ind.

3.0371, DETERMINE LIGNIN STRUCTURE AND BIOSYNTHESIS

O.E. NELSON, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01414)

OBJECTIVE: Determine the availability of sites for esterification on the 'cores' of normal, bm(1) and bm(2) alkali lignin and solvent- extractable lignin before and after de-esterification. To determine the incorporation of phenolic monomers into the lignin 'cores' of normal, bm(1) and bm(2) corn vs. esterification onto the 'cores'. To elucidate the enzymatic reactions by which p-hydrocycinnamic and ferulic acids are esterified onto the lignin 'cores' in normal, bm(1), and bm(2) corn. To compare the phenoloxidase and peroxidase activity of normal corn with the mutants. To determine the lignin content, the composition of the 'cores', and the phenolic acids esterified onto the 'cores' for bm(3) and bm(4) mutants and the double mutants bm(1) bm(2), bm(1) bm(3), bm(1) bm(4), etc.

APPROACH: A comparison of the effects of the mutants bm(1), bm(2), bm(3), bm(4) with those of the double mutants may make it possible to ascertain which mutants are affecting early steps in lignin formation and which are affecting later steps.

PROGRESS: A group of recessive mutants in maize, the brown-midrib mutants, owe their visual differences from normal plants to the production of abnormal and colored lignins. Alkaline hydrolysis of mutant and normal lignins liberates P-coumaric and ferulic acid with a marked reduction in yield of P-coumaric acid from the brown-midrib-1 (bm(1)) mutant and its double mutants. Syringaldehyde, vanillin and P- hydroxybenzaldehyde are obtained after alkaline nitrobenzene oxidation of the lignins. The yield of syringaldehyde from all double mutants and the bm(1) and bm(2) and bm(3) mutants was less than that from normal maize. Greatest reduction of syringaldehyde occurred with bm(1) and its double mutants. Molecular core of bm(1) has carboxyl groups and these may account for its highly cross-linked nature. The bm(1) mutant may be less able to reduce carboxyl groups and/or hydroxylate the benzene ring to the syringaldehyde pattern. This results in the incorporation of an 'abnormal' component into the lignin core. Since lignin comprises 15- 25% of the dry weight of wood and many crop residues, knowledge of its biosynthesis and structure are valuable to the paper industry and in utilization of farm residues.

SUPPORTED BY Indiana State Government

3.0372, EVALUATION OF DEHULLED SOYBEAN GRITS FROM UNITED STATES VARIETIES FOR MAKING MISO

H. EBINE, Central Miso Institute, *Tokyo, Japan* (UR-A11-(40)-2)

PROGRESS: Final report has been received. Over 100 different commercial varieties of soybeans were studied as well as 24 Japanese samples. U.S. varieties found most suitable for making miso were Kanrich, Mandarin, and Comet. Seven other varieties and unnamed selections offered promise. Evaluation of the soybean grits method gave products with excellent color and flavor, and the organoleptic tests showed the miso to have a less beany flavor. This method gave high quality miso but had the disadvantage of a higher loss of water-soluble material than the whole bean fermentation. Some studies were made to determine if the soluble waste could be used as a substrate for cultivation of the mold that makes enzymes for miso production. The mold did not make the proper enzymes on this substrate. Statistical data on miso production in Japan are presented in this report.

SUPPORTED BY U.S. Dept. of Agriculture

3.0373, SINGLE CELL PROTEINS FROM CELLULOSIC WASTES

C.D. CALLIHAN, Louisiana State University, School of Engineering, *Baton Rouge, Louisiana* 70803

Due to the rapid increase taking place in the nation's and the world's population, serious pollution problems and shortage of food will have to be overcome. Cellulosic wastes from agriculture, industries and municipalities constitute a major portion of the

solid wastes, and these wastes can be converted to useful products. One of the most important products to which it can be converted is protein. Protein is the component in food and animal feed that is in shortest supply.

A versatile, continuous, chemical-microbial pilot unit is under construction. On completion it will be able to process a multiplicity of cellulosic wastes converting them to single cell protein using an organism that has already been isolated in our laboratories. Studies will be conducted with the pilot unit to evaluate the various cellulosic wastes as substrates for microbial growth and to determine the optimum conditions for economic operations. Also, other cellulolytic organisms will be investigated for their substrate specificity. As an integral part of the project the nutritional value, digestibility and toxicity of the single cell protein product will be determined. Studies will also be conducted to direct the product improvement.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0374, RESEARCH STUDIES RELATED TO DEVELOPMENT OF A CRAWFISH PROCESSING INDUSTRY IN LOUISIANA

R.T. LOVELL, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB01391)

OBJECTIVE: The objectives of the study were to derive information which would be pertinent to the growth of the crawfish processing industry in Louisiana which included processing and market product recommendations, plant and equipment designs, potential crawfish supply and sources, public health aspects of crawfish as a food, utilization of waste material, and locations for plants.

APPROACH: Crawfish samples were collected during the 1966 and 1967 seasons for laboratory studies concerning bacteriological and chemical analysis data, processing methods, and product development. Survey data was collected from persons and agencies associated with the crawfish industry in the state. Plant designs and equipment were developed by cooperative work with engineering personnel from within and outside the University. Final recommendations were compiled in manuscript form and distributed to persons and agencies interested in the crawfish processing industry.

PROGRESS: Contacts with national food and industrial organizations have been established pursuant to applied development of the Louisiana crawfish industry for production of gourmet food items and utilization of waste products for animal protein feed purposes. Examination of organoleptic and overall consumer attractability of presently prepared crawfish products is in progress by these firms in conjunction with personnel and facilities of the Food Science and Technology Department. Economic and production factors of the industry are being evaluated to establish feasibility of large-scale resource input. Biological characteristics of the animal, pertinent to intensive cultivation on a predictable basis, are also under study.

SUPPORTED BY Louisiana State Government

3.0375, BARK RESIDUES AS SOIL CONDITIONER

O.L. FITZGERALD, Louisiana Technological Univ., School of Forestry, *Ruston, Louisiana* 71270 (LAZ00003)

OBJECTIVE: Determine the value of bark in three sizes as a mulch for horticulture plants. Determine the economic feasibility of marketing processed bark on a local and regional basis for use as a mulch or soil conditioner.

APPROACH: Various treatments of the bark will include composting untreated as well as with different mixtures of nutrients added prior to composting. This will be followed by a shredding operation to alter the bark to various sizes. These sizes and mixtures will be tested on field grown and container plants. Data resulting will be statistically analyzed to determine the value of these materials as mulch or soil conditioner.

PROGRESS: The manuscript for the first two-year mulch project should be published during the next three months. Dr. Wright will present a portion of this report at the Southern Agriculture-Workers meeting in Mobile, Alabama on February 5, 1969. Work has been started on renovating the beds used for a previous crop of roses grown in media where bark, sawdust and peat were used as an amendment. These beds will be tested for mineral content, for organic matter and for density. New soil will be added to raise the beds to 9 inches above ground level. Four varieties of Hybrid Tea roses will be grown and production records kept for a two year period. Further work with tomato plants grown in mixtures containing bark will be attempted.

SUPPORTED BY U.S. Dept. of Agriculture

3.0376, FEEDING BROILER LITTER TO DAIRY REPLACEMENT HEIFERS

H.H. BRUGMAN, Univ. of Maine, Agricultural Experiment Sta., *Orono, Maine* 04473 (ME03115)

OBJECTIVE: Determine cost and feasibility of feeding broiler litter to replacement dairy heifers.

APPROACH: Cost of feed, growth rates and fertility data will be collected from dairy calves fed a broiler litter and grain ration following the initial milk replacer-calf starter period of about eight weeks. The animals will be bred at about 15 months of age. The problem of drugs, antibiotics, other feed additives and their derivatives and their possible effect on human and animal health will be studied. The time for discontinuing the feeding of broiler litter prior to milk production age will be determined.

PROGRESS. In order to save cost and time preliminary work is conducted with sheep object is to develop a low priced ration suitable to automatic feeding. All concentrate ration containing 20% sawdust as a fiber source plus barley and S.O.M. as control and rations containing 20% sawdust, barley and poultry litter with and without ampro-plus and rumen inoculant added. Feed efficiency was greater in lots fed poultry litter than the control ration, ampro-plus retarded growth in lambs under 70 lbs. No effect was found when rumen inocculant was added. Rations containing urea were less efficient than the control ration. Six Hereford heifers were weight-gain tested. The index varied from 1.71 to 2.52. One bull was tested and his index was 3.39.

SUPPORTED BY Maine State Government

3.0377, BIODEGRADATION OF POULTRY MANURE

C.C. CALVERT, U.S. Dept. of Agriculture, Animal Science Research Div., *Beltsville, Maryland* 20705 (032911590121073)

OBJECTIVE: Develop biological methods for odor control, volume reduction and the production of useful products from poultry manure.

APPROACH: The procedures used will be to determine whether coprophagous insects such as the house fly and/or unicellular organisms can degrade poultry manure and reduce or eliminate odor, reduce volume and produce a useful protein byproducts. The nutritive value of fecal material after treatment will be determined by feeding them to the chicken and other animals.

PROGRESS: Poultry manure seeded with house fly eggs loses approximately 46 percent of its original water content. The manure after larvae development was essentially odorless, and loose and crumbly in texture. The material is easily pelleted. It contains about 2 percent nitrogen and may have use as a fertilizer and soil conditioner. A patent application has been made for a device to separate larvae from the manure. The fly pupae contains about 63 percent protein, with a good amino acid profile, and is the equivalent of soybean meal in supporting chick growth. The pupae yield is about 3-4 percent of fresh manure.

3.0378, RECOVERING AND REFINING SECONDARY METALS AND ALLOYS

H.S. CALDWELL, U.S. Dept. of the Interior, Bureau of Mines, *College Park, Maryland* 20740

A series of investigations is being conducted to develop new and improved processing techniques for reclaiming metal values from scrap and mineral processing wastes. Research now in progress includes: (1) the determination of optimum experimental conditions and reagents required to remove antimony from bronze and brass scrap and lead and tin from aluminum scrap by the use of intermetallic compound formation; (2) the removal of

chlorine from sal skimmings to produce a dry zinc oxide ash suitable for smelting; (3) investigation of vacuum distillation methods for removing volatile constituents from complex nonferrous scrap mixtures to produce commercially acceptable metals or alloys; (4) investigation of use of carrier gases to enhance the degree of separability and the rates of distillation of volatile metals at temperatures below the boiling point; (5) development of improved amalgam, electrorefining and electrowinning techniques for separating and refining metals from complex nonferrous scrap metal mixtures; (6) investigation of hydrometallurgy methods for extracting and recovering tin from detinning tank slimes; (7) development of hydrometallurgical methods for reclaiming metal and mineral values contained in incinerator process, and (8) a systems study that will permit selecting effective combinations of refining techniques for optimum recycling of complex secondary metals and waste materials.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0379, RECOVERY OF COPPER AND OTHER BASE METALS FROM COMPLEX METAL MIXTURES

H.S. CALDWELL, U.S. Dept. of the Interior, Bureau of Mines, *College Park, Maryland* 20740

The overall objective of the project is to develop methods for identifying, sorting, and separating metals to allow more efficient recycle of scrap and other complex metal mixtures.

Research Investigations in Progress are as follows: A. Devise simple, versatile, inexpensive identification methods to classify a wide variety of copper-base scrap with reasonable certainty. Colorimetric, X-ray, and chemical methods are being studied. B. Develop methods for removing lead from copper-base scrap that cannot be efficiently sweated. Flux refining and intermetallic compound formation methods are being studied. C. Determine if vacuum distillation is both technically and economically feasible for treating galvanized steel scrap to upgrade the scrap for steelmaking and recovering a marketable zinc product.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0380, EXTRACTION OF METAL AND MINERAL VALUES FROM MUNICIPAL REFUSE AND INCINERATOR RESIDUES

M.H. STANCZYK, U.S. Dept. of the Interior, Bureau of Mines, *College Park, Maryland* 20740

Research currently is aimed at developing continuous methods for recovering various metal and mineral values from municipal incinerator residues and refuse, and refining of these materials into products suitable for recycling back into our economy. A small prototype continuous pilot plant is being designed and developed for separating residues into fractions suitable for further metallurgical processing. As data from this pilot plant is developed, performance results are being evaluated for determining materials and energy balances, relative equipment size and operating costs for a semi-commercial size plant. Chemical processes for preparing premium grades of iron scrap from ferrous fractions and for recovering precious metals from fly ash also are being developed. Physical processes for producing an uncontaminated glass fraction, and separating clear glass from colored glass are being investigated.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0381, ENHANCED CELLULASE PRODUCTION BY MUTATION

M.H. MANDELS, U.S. Army, Natick Laboratories, *Natick, Massachusetts*

Technical Objective: Increase degradation of cellulose by mutation to develop strains that produce greater quantities or cellulolytic enzymes and/or enzymes having greater specific activity on cellulose. Enzymatic degradation to convert cellulosic waste to food appears feasible. More active enzyme preparations will increase the rate of breakdown, reduce or eliminate pretreatment of the substrate, and improve the economic potential of the process.

SUPPORTED BY U.S. Dept. of Defense - Army

3.0382, SCRAP AND RECYCLE RESEARCH

N.B. MELCHER, U.S. Dept. of the Interior, Bureau of Mines, *Saint Paul, Minnesota* 55111

To develop efficient methods for recovering and reusing iron, steel, and ferroalloy metal scrap and waste and to reduce or eliminate environmental pollution and disposal costs.

Continue research on production of foundry iron from ferrous scrap. Work will be conducted to produce commercially acceptable foundry iron and synthetic foundry pig iron from ferrous scrap. Automobile and other ferrous material will be blended as required. Foundry iron and synthetic foundry iron will also be produced using prereduced pellets.

Continue research on a selective oxidation of ferrous scrap to produce a high quality iron oxide and a clean residual scrap iron of high purity, and devise methods to recover the nonferrous elements. Investigate more fully the effect of process variables such as time, temperature, and gas atmosphere; to determine the effect of oxidation promoters and the influence of nonferrous contaminants on process reactions.

Provide supporting petrographic services to examine raw materials and reduced products by microscope and X-ray; describe and photograph pellet microstructure as required.

Conclude research on recovery of copper from high copper-bearing materials, such as armatures and motors.

Investigate the kinetics and mechanism of oxidation of steel scrap with carbon dioxide, water vapor, and their mixtures with nitrogen, carbon monoxide, and hydrogen.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0383, SYNTHESIS OF L-DOPA FROM WOOD PULP WASTE

F. GILMORE, Univ. of Mississippi, Graduate School, *University, Mississippi* 38677

No summary has been provided to the Science Information Exchange.

SUPPORTED BY Mississippi State Government

3.0384, RECYCLING OF STEELMAKING FURNACE DUSTS

P.G. BARNARD, U.S. Dept. of the Interior, Bureau of Mines, *Rolla, Missouri* 65401

To develop treatments for removing certain deleterious elements from iron foundry and electric furnace and BOF steel making dusts that will permit recycling of the iron-rich residue and recovery of the nonferrous metals in usable form. (1) Continue research to develop treatments for removal of zinc, lead, and copper to levels that allow recycling of iron-rich residue in the steel plant. (2) Make a suitable agglomerate, low in lead and zinc, by simultaneous reduction-induration of pellets. Investigate the addition of coarsening agents as coke breeze, fine sinter, or mill scale to improve pelletization chaacteristics of the dust. Study the possible elimination of lead and zinc by reduction of small pellets. (3) Develop economically and technically feasible methods for recovering zinc, lead, and copper from steel furnace and iron foundry dusts.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0385, UTILIZATION OF PROCESSING WASTES AND SCRAP

L.W. HIGLEY, U.S. Dept. of the Interior, Bureau of Mines, *Rolla, Missouri* 65401

To develop low-cost procedures for the extraction of metals, metal compounds, and minerals from base metal processing wastes; and to determine new applications for the utilization of low-grade base metal scrap.

Specific elements of the objective are substitution of zinc die-cast scrap for high-purity zinc in desilvering of lead bullion, and recycling of zinc retort residues, electrolytic zinc plant leach

residues, and copper alloy furnace dusts. Research on these materials is needed to develop uses, rather than discarding as wastes in some instances, and to overcome underutilizationn in other instances.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0386, UTILIZATION OF WASTE PLASTICS FROM URBAN REFUSE

J.L. HOLMAN, U.S. Dept. of the Interior, Bureau of Mines, *Rolla, Missouri* 65401

The overall objective is to develop methods for making use of plastics discarded in urban waste. Plastic disposable consumer products will be characterized as to distribution of types and formulations. Adhesive bonding of mixed plastics will be investigated and bulk properties of scrap plastic compared with those for virgin plastic as new uses are sought for mixed plastic scrap. The feasibility of using scrap polyvinyl chloride as a source of HCl or C12 in metallurgical processes will be emphasized. Since large-scale use of plastics is creating a serious problem because of unsatisfactory disposal methods, this project is aimed at making useful products from plastic wastes.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0387, TUBE TRANSPORT - AN IMPROVED CONCEPT OF URBAN REFUSE COLLECTION, TRANSPORTATION AND RECYCLING

B.G. WIXSON, Univ. of Missouri, School of Engineering, *Rolla, Missouri* 65401

An improved concept for the processing and tube transport of urban solid wastes was achieved by a grinding process coupled with the transportation of wasted suspended in an improved emulsion. An experimental pilot-plant was constructed using a hammermill, a 20 HP electric motor, a SWG 12H type CDQ Moyno sewage pump and one hundred foot loop of four inch PVS pipe discharging into a 300 gallon reservoir. An experimental chemical material was furnished by the Petrolite Corp., St. Louis, to form a very thick emulsion that would liquidize under pressure, and jell and suspend ground particles if pumping pressure was released. The emulsion was made with water and served as a lubricant to the pump and pipe during operation.

Solid wastes used in the study were derived from ordinary municipal refuse. Reduction of wastes was generally feasible by use of the hammermill. Tube transport flow tests were carried out to compare the differences between the use of water and emulsion as the transport media for urban wastes. The emulsion was found to be superior to water by (1) permitting larger, denser particles of processed solid wastes to be carried without the settling problems normally encountered when water was used as the transporting media; (2) Shredded wastes could be separated from the emulsion and the emulsion could be reused; and (3) the emulsion acted as a lubricant and reduced wear on pumps and pipes.

Research is continuing to determine the economic and applied value of such a system to crowded urban environments. New concepts developed from this study would assist in rehabilitating some urban environments and planning future urban communities to avoid refuse problems.

SUPPORTED BY University of Missouri

3.0388, USE OF POULTRY FAT AND MEAT SCRAPS

G.W. FRONING, Univ. of Nebraska, Agricultural Experiment Sta., *Lincoln, Nebraska* 68508 (W6-1-72(C))

OBJECTIVE: Find remunerative uses for poultry meat and fat recovered from the less valued parts of the carcass.

APPROACH: Emulsifying and cohesive properties of variously treated poultry parts such as backs, neck, skin and fat will be determined and evaluated in terms of comminuted sausage-type products.

PROGRESS: Turkey muscle protein was fractionated into actin, myosin, actomyosin, and a total gross myofibril fraction, and the emulsifying characteristics of these fractions were determined. Actin had an extremely high emulsifying capacity; its upper limit was not established. Emulsifying capacity for the other fractions decreased in the following order: actomyosin, myosin, myofibrils, and finally whole meat. Emulsion stability paralleled emulsifying capacity. The superior emulsifying capacity of prerigor muscle to post rigor muscle could be duplicated in post rigor muscle by adjusting the pH back to prerigor levels. Blending deboned meat with salt and holding for 24 hours at 35 F. before chopping, and higher levels of salt in the sausage formulation, both reduced gel-water release and solids release from the subsequently formed emulsions, and also reduced cooking loss. Combination of mechanically deboned turkey meat and soybean protein (at 25% of total protein) was found to give a satisfactory sausage. Optimum conditions were established for utilization of Paoli deboned turkey frame meat and Bebun deboned turkey frame meat. It appears that there is a need to standardize these products, in terms of fat content and tissue constituents, if they are to attain wide commercial usage.

SUPPORTED BY U.S. Dept. of Agriculture

3.0389, SOIL PRODUCTIVITY AS AFFECTED BY MICROBIAL ACTIVITY IN CROP RESIDUES AND ANIMAL WASTES

T.M. MCCALLA, Univ. of Nebraska, U.S.D.A. Soil & Wa. Cons. Div., *Lincoln, Nebraska* 68503 (SWC-031-DLI-4)

OBJECTIVE: Determine the effects of crop residue management and animal waste additions on the kinds and number of microorganisms in soils, their release of nutrients and production of toxins, and the significance of such microbial activity to crop production.

APPROACH: Laboratory and filed investigations will be conducted on the effects of kinds and amounts of crop residue and animal waste additions and management on the kinds and numbers of microbes in soils, the rate of release of plant nutrients and the production of plant growth promoting and inhibiting compounds. Microbial activity will be related to soil moisture, temperature and aeration conditions. Chemical analyses and bioassays will be conducted to determine the nature and amounts of toxins produced.

PROGRESS: Penicillium urticae populations as high as half of the total fungal populations were found in soil samples from spring and fall soil samples taken from stubble-mulched wheat fields in five states. The mold produces the phytotoxin, patulin. Concentrations as high as 75 p.p.m. of soil were extracted from stubble-mulched soil. Patulin applied to plots of wheat at three locations in Nebraska for 3 years reduced germination, tillering, survival and yield when applied at seeding. Spring applications reduced height, grain yield, and kernel size. Effects on yield were less the later the patulin was applied. Yield reductions as high as 26 percent have been noted in the field, but the toxicity depends on field conditions that are poorly understood.

SUPPORTED BY U.S. Dept. of Agriculture

3.0390, CHEMICAL PROCESSING OF ITANIUM SCRAP AND RESIDUES. TITANIUM CHLORINATION RESIDUES

C.C. MERRILL, U.S. Dept. of the Interior, Bureau of Mines, *Boulder City, Nevada* 89005

Purpose: Develop methods to recover and recycle the metal values resulting from the wastes produced in the production of titanium tetrachloride. This waste material contains niobium, tantalum, titanium, zirconium, vanadium, chromium, iron, and aluminum. Methods of separating these elements will be studied, and procedures will be developed for the recovery of the valuable components.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0391, ELECTROLYTIC REFINING OF ALUMINUM SCRAP

T.A. SULLIVAN, U.S. Dept. of the Interior, Bureau of Mines, *Boulder City, Nevada* 89005

Purpose: To improve processes for reutilization of metal and mineral values for which present commercial methods are inadequate or inefficient.

3. SOLID WASTE MANAGEMENT

Initial work will explore the use of the 'Hoopes type cell' to produce high-purity and/or aluminum base alloys from aluminum scrap metal products with particular emphasis on abundant low value scrap or waste metal.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0392, A NEW PRACTICAL APPROACH TO DAIRY WASTES
W.K. JORDAN, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00311)

OBJECTIVE: Find methods to reduce waste water volume through reuse. Recover food materials for human use and animal feed. Realize savings through reuse of cleaning compounds. Reduce over-all use of water and provide an effluent from the food plant that minimizes contamination of ground and surface waters.

APPROACH: Effluent from the University dairy will be examined for amount, B.O.D., fat and solids, alkalinity, and bacterial count. Salvage of food material will be by separation or concentration. Potential reuse of cleaning solutions will be determined in the laboratory and then in the plant. Modification of plant practices will be tried to minimize water use.

PROGRESS: A study of the temperature, composition, and flow of all effluent from the University dairy plant led to improved plant practices resulting in savings of water, fuel, detergents, and edible food solids. Although approved, the project has not been funded. No additional work has been started.

SUPPORTED BY U.S. Dept. of Agriculture

3.0393, TREATMENT AND UTILIZATION OF WASTES
F.J. HUMENIK, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC03295)

OBJECTIVE: Investigate biological methods for removal and conservation of nutrients from agricultural, processing and domestic waste; examine methods for conversion of harvested biomass nutrients into a suitable high protein food.

APPROACH: A symbiotic algal-bacterial system will be developed toward practical applications for removal and conservation of wastewater nutrients. Applicable algal species will be investigated and ecological relationships considered in determining the optimum environmental and operating conditions. Methods of harvesting and processing algal- bacterial biomass for producing a high protein food will be examined.

PROGRESS:

SUPPORTED BY U.S. Dept. of Agriculture

3.0394, WOOD RESIDUE PRODUCTION AND FEASIBILITY OF CONVERSION TO A SALEABLE PRODUCT
D.H. STEENSEN, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC04022)

OBJECTIVE: Determine the amount of wood residues produced and the amount currently contributed to air and ground pollution: locate those areas capable of supporting a residue-using firm: and determine the economic feasibility of converting wasted wood to a saleable product.

APPROACH: Primary wood-using firms will be surveyed. Collected data will be used to generate production coefficients suitable to up- dating the survey and analyzing the economics of waste conversion.

PROGRESS: Initial and follow-up contacts have been held with the cooperator, North Carolina Department of Conservation and Development to assay the volume and types of wood residue being generated in primary conversion plants in North Carolina. Preliminary studies have been made to conduct a study of residues being generated in N. C. furniture plants and possible avenues for their salability.

SUPPORTED BY U.S. Dept. of Agriculture

3.0395, SYNTHETIC FILLER FOR USE IN HIGHWAY CONSTRUCTION
R.F. STOOPS, Univ. of North Carolina, School of Engineering, *Raleigh, North Carolina* 27600

The objective of this preliminary investigation is to determine the feasibility of developing a low-cost synthetic filler for asphalt and concrete pavements. The material will be designed for high skid resistance and night visibility. It will be a crystallized glass made from readily available waste products insofar as possible. Work will include making glasses, crystallizing them, and evaluating their properties. Differential thermal analysis, x-ray diffraction, and electron microscopic techniques will be used to determine optimum crystallization conditions. Properties such as hardness, crushing strength, whiteness or reflectivity, wear and skid resistance, chemical corrosion resistance, and oil penetration will be determined. The project began on 1 July 1970 and should be completed by 31 December 1971.

SUPPORTED BY North Carolina State Government - Raleigh

3.0396, FERRIC CHLORIDE PROCESSING
F.E. BLOCK, U.S. Dept. of the Interior, Bureau of Mines, *Albany, Oregon*

OBJECTIVE: To develop a process for the recovery of chlorine and a usable iron oxide byproduct from waste iron chlorides generated in the direct chlorination of ilmenite to produce $TiCl_4$.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0397, UTILIZATION OF WASTE BARK
R.A. CURRIER, Oregon State University, School of Forestry, *Corvallis, Oregon* 97331

Specific Aims of this proposal: Physical: 1. To study the formation of pellets from bark as a model system for the preparation of other molded products from bark. 2. To determine which basic information obtained from pelleting studies may be extrapolated for use in preparing other molded and extruded articles from bark, or mixtures of bark and plastics.

Chemical: 1. To obtain a more detailed description of bark, particularly the carbohydrate and polyphenolic polymers, i.e. bark phenolic acids, phlobaphenes, tannins and 'bark lignin' fractions. 2. To prepare derivatives (acetate esters, methyl ethers) of the polysaccharides and compare their properties with those of carbohydrate derivatives presently in commercial use. 3. To determine the reactivity of these chemical components with ammonia and their role in the fixing of nitrogen in bark.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0398, CONVERTING INCINERATOR RESIDUE TO USEFUL MATERIALS
P.E. MORGAN, Franklin Institute, *Philadelphia, Pennsylvania*

Work will be extended to produce at least 600 lbs. of road aggregate material for testing by Federal and State highway authorities. Possible uses for incinerator ash for cement, as a soil will be pursued; for the latter some plant growth studies are being examined free of charge to this project. An economic study of processing and the logistics of transportation, sociological implications etc. will be carried out by people skilled in chemical engineering and systems science. Recommendations will be made at the end of the period for scale up to a pilot plant suitable for a demonstration project.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0399, CONVERSION OF POULTRY MANURE TO USEFUL PRODUCTS
G.O. BRESSLER, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01829)

OBJECTIVE: Develop for layers automatic system drying manure to low level moisture; eliminate obnoxious odors for manure use in plant growth media; prepare products by combining dry manure or ash with anthracite refuse to test under greenhouse and field conditions.

APPROACH: Dry manure from 80% to 30% moisture by stirring, aerating. Dry from 30% to 9% commercial dryer. Obtain least cost combination. Develop automatic system for floor and cage operations. Determine relationship of stirring aerating manure and production obnoxious odors. Establish minimum

commercial dryer temperatures to achieve moisture stability, minimize microiorganisms, retain maximum plant nutrients. Combine dry or ashed poultry manure with anthracite refuse other waste products. Conduct greenhouse and field trials for physical and chemical capability product or plant growth. Apply to strip mine and spoil banks to establish cover crops. Measure benefits to soil and acidity.

PROGRESS: An automatic system of drying poultry droppings inside a poultry house to about 30% moisture and to less than 10% moisture in a commercial dryer has been developed. Mechanical difficulties in equipment require further developmental work. The dried poultry manure has been applied with a hydro-seeder to experimental plots on coal mining spoil bank land, on divider strips and highway embankments and on a dam breast. Manure treated plots were compared with plots treated with lime and fertilizer according to Penna. Department of Highways recommendations. All plots were seeded with a slope mix grass and Crown Vetch seed mixture. By the end of the summer the growth of grass and vetch on the manure plots was just as satisfactory as on the fertilizer and lime treated plots. Use of the commercial dryer operated at 250 F. cut bacterial counts in the manure from as high as 31 billion per gram to as low as 400,000 organisms per gram of manure. Enteric type bacteria were reduced from 24 million to as low as 400 per gram of manure. Greater root nodulation has been found with Crown Vetch and beans where dried manure was applied to the soil compared with lime and fertilizer plots. No Salmonella organisms were isolated from the dried manure.

SUPPORTED BY U.S. Dept. of Agriculture

3.0400, REUSE OF PLASTICS RECOVERED FROM SOLID WASTES

D.R. PAUL, Univ. of Texas, School of Engineering, *Austin, Texas* 78712

It is estimated that about 90% of all plastics in municipal refuse are the chemical types polyethylene, polystyrene, and poly(vinyl chloride). The remaining 10% includes a broad assortment of chemical types. Development of suitable processing schemes and demonstration of desirable properties of the reprocessed materials is a necessary first step. Initial work will be restricted to the three types of plastics predominant in wastes. Fundamental properties of plastic blends made from these materials will be examined. If reuse can be made possible, this will eliminate the need to dispose of this segment of municipal or industrial solid waste. The sale of recovered plastics will provide an additional source of income to aid the finances of solid waste disposal and/or use.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0401, PHYSICAL AND CHEMICAL PROCESSING OF FERROUS SCRAP

C.J. CHINDGREN, U.S. Dept. of the Interior, Bureau of Mines, *Salt Lake City, Utah* 84112

Develop improved procedures for recovering marketable steels, cast iron, and nonferrous metals from scrapped automobile. Construct and test improved automobile incinerator. Devise methods for recovering byproducts from nonmagnetic discard of automobile shredding plants.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0402, RECOVERY OF HEAVY METALS FROM ELECTRONIC SCRAP

R.O. DANNENBERG, U.S. Dept. of the Interior, Bureau of Mines, *Salt Lake City, Utah* 84112

Develop improved processes for recovering gold, silver, copper, and other precious and base metals from diverse types of electronic scrap.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0403, WOOD WASTE REUSE IN CONTROLLED RELEASE PESTICIDES

G.G. ALLAN, Univ. of Washington, School of Forestry, *Seattle, Washington* 98105

The broad aim of this research is to reuse solid waste such as bark, pulping wastes and screenings, lignin and sawdust.

This will be done by first recognizing that all these solid wastes are abundant low-cost polymers containing replaceable hydrogen atoms.

Secondly, these polymers will be employed as substrates to which pesticides can be chemically attached to afford inactive solid waste- pesticide combinations.

Finally, these combinations will be so designed as to slowly release the active pesticide over the desired period of time thus improving their safety and efficiency and permitting the use of new more transient and readily metabolized pesticide materials.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0404, MINERALS AND SULFUR MODES IN COAL

C. KARR, U.S. Dept. of the Interior, Bureau of Mines, *Morgantown, West Virginia*

Purpose: A. To determine specific minerals in coal, fly ash, boiler deposits, waste coal, and similar materials, and their amounts, using original methods based on mid- and far-infrared spectroscopy and nuclear quadrupole resonance spectroscopy. Relationships between various inorganic chemicals in particulate pollutants and in boiler deposits with the minerals in coal can be established, and economic utilization of valuable minerals in coal and coal waste can be advanced. (B) To determine the various specific modes of occurrence of sulfur in coal, beyond the conventional, unspecific, wet-chemical determination of 'pyritic,' 'sulfate,' and 'organic' sulfur, by means of Sulfur-33 wide- line nuclear magnetic resonance spectroscopy. This vital information has a direct bearing on sulfur removal processes, and other problems associated with sulfur in coal.

3.0405, STABILIZING SANITARY LANDFILLS BY INJECTION GROUTING

L.K. MOULTON, West Va. University, School of Engineering, *Morgantown, West Virginia* 26506

The primary objective of the proposed research is to determine the effectiveness of injection grouting in accelerating the stabilization of sanitary landfills so that landfill sites can be reclaimed and put to higher use in the shortest possible time. Particular emphasis will be given to the use of grouts made with waste products such as flyash and bottom ash. The study will include an evaluation of the effect of various grouts on (a) the strength and settlement characteristics of laboratory compacted samples of refuse and (b) the process of biological decomposition with respect to its influence on strength, settlement and gas production. These laboratory investigations will be augmented by a limited field study of the effectiveness of grout stabilization.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

3.0406, TECHNICAL AND ECONOMIC EVALUATION OF PROCESSES TO MANUFACTURE USEFUL PRODUCTS FROM LIMESTONE MODIFIED FLYASH

UNKNOWN, West Va. University, Graduate School, *Morgantown, West Virginia* 26506

Description: Evaluate the technical and economic feasibility of a number of potential new uses for the limestone-modified fly ash that will result from limestone injection processes for the abatement of sulfur oxides which result from the combustion of fossil fuel. Laboratory experimentation will be conducted to determine the feasibility of manufacturing specific products and to evaluate the quality of the products. Pilot-scale units will be set up to further assess process conditions and economics for the most promising utilization schemes.

3.0407, PAPER AND FIBERBOARD PROCESSES
D.J. FAHEY, Univ. of Wisconsin, U.S.D.A. Forest Products Lab., *Madison, Wisconsin* 53706 (FPL3304)

OBJECTIVE: Determine optimum conditions for making paper products from wood; extend use of present fibers and use fibers from unused species.

APPROACH: Study hardwood pulps for products, chemical additions on wet and dry webs, prediction of rate of water removal on paper machine wire, effect of restraint during drying on paper dimensional stability, ways of obtaining building fiberboard quality improvement, chemicals to reduce loss of paperboard strength when exposed to moisture, heat treatment and cross linking to improve paper dimensional stability. Study paper machine variables, paper chemical combinations, paper wood composites, paper and other materials such as films and other reinforcements.

PROGRESS: Further studies have confirmed earlier findings that gyratory refining reduces the tendency of the short, wide, barrel-shaped vessel elements present in oak pulps to cause picking problems both in manufacture and in printing of paper. The resistance to printing pick was also greatly improved with a potato starch applied to the surface of a low moisture sheet. Corrugating runnability was shown to be strongly related to the sheet properties of stretch, folding endurance, and ring crush. Shives were detrimental and some long fiber pulp was necessary with hardwood semichemical furnishes. This information assists the corrugating industry in achieving maximum production from their present facilities. Studies showed the importance of certain headbox variables such as consistence in achieving more of the potential strength of papermaking furnishes. The better strength will allow a reduction in weight of paper thus more efficiently utilizing the fiber and also reduce the transportation cost.

SUPPORTED BY U.S. Dept. of Agriculture

3.0408, PROJECT B - CONVERSION OF OIL SHALE AND SHALE OIL - PART 2 - IN SITU RETORTING OF OIL SHALE
H.C. CARPENTER, U.S. Dept. of the Interior, Bureau of Mines, *Laramie, Wyoming*

This project is concerned with studying methods for converting the organic portion of oil shale to shale oil and other useful products by retorting the shale in place. Typical of the research that is being conducted are studies of both nuclear and nonnuclear techniques for fracturing oil shale to induce permeability and studies of the basic factors inherent to recovering the shale oil from the fractured mass by in situ retorting. These factors include igniting the shale, determining air flows and requirements, and recovering the oil. The research also includes a study of the retorting characteristics of ungraded oil shale such as that which might be expected to exist as rubble in a nuclear chimney. A large part of this study is being carried out in an internally fired batch retort having a nominal capacity of 150 to 200 tons of oil shale.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0409, SUPPORTING RESEARCH FOR IN SITU RESEARCH
A.W. DECORA, U.S. Dept. of the Interior, Bureau of Mines, *Laramie, Wyoming*

The objective of this research is to support the in situ oil-shale retorting research by obtaining fundamental knowledge of the kinetics and mechanisms of the reactions occuring during the in situ retorting of oil shales and during the conversion of the initial crude product to usable end product. Intermediate objectives are the determination of reaction parameters for thermal reactions, photochemical reactions, and oxidation reactions on oil shales and shale oils. To apply these parameters to the processes used to produce shale oils and to the processes for conversion of shale oils to end products. This project is reviewed and revised yearly.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

3.0410, CHARACTERISTICS OF CRUDE OILS
J.C. MORRIS, U.S. Dept. of the Interior, Bureau of Mines, *Laramie, Wyoming*

Each year 50 to 100 selected samples of crude oils from the Rocky Mountain area and Alaska are analyzed by the Bureau of Mines method. The samples are selected from among the new fields and new production in older fields on the basis of their geologic, geographic, and/or economic significance. The analyses are placed in open files for use by the public, and selected data from the analyses are coded on punch cards for machine computation. Correlations of geological occurrence with composition are being made for fields in Utah, Alaska, and Wyoming.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

DESCRIPTION OF RESEARCH TASKS

4. PESTICIDES

A. AIR OR WATER ENVIRONMENTS Aerial Drift, Atmospheric Contamination, Or Aquatic Environmental Cycling of Pesticides.

4.0001, ENGINEERING TECHNOLOGY FOR APPLICATION OF AGRICULTURAL CHEMICALS
W.T. DUMAS, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA00242)

OBJECTIVE: Improve agricultural chemical application equipment to increase efficiency of application and use of chemicals in cotton production in the Southeast. Evaluate and improve machines, practices and combinations of practices for more efficient weed control in cotton in the Coastal Plain area of the Southeast.

APPROACH: Conduct laboratory and field studies to determine optimum number and arrangement of nozzles per row and optimum volume of spray solution required for most efficient application and utilization of agricultural chemicals. Measure penetration, distribution and drift by use of dyes, fluorescent tracers, chemically sensitive cards and by plant response. Mechanical and flame cultivation practices will be studied in combination with herbicide applications to determine relationship between mechanical, flame and chemical systems of weed control in cotton. Develop an economical system of weed control for the Southeastern Coastal Plain area.

PROGRESS: All nozzle arrangement treatments have resulted in good boll weevil and bollworm control and have yielded almost twice as much seed cotton as the untreated check. Five different ULV formulations of insecticides were applied with the John Blue mist blower and one formulation with the Span Spray Row Crop Sprayer. All treatments resulted in good insect control and significant increases in yield when compared to the untreated check. Span Spray plots yielded somewhat more cotton than the John Blue plots, however, the differences were not significant. Tests were conducted to compare the relative resistance of an ULV and EC formulation of an insecticidal spray to 'wash-off' by simulated rainfall. Data on boll weevil and bollworm infestations indicate that both insecticidal treatments resulted in good control. Insecticide treatments yielded more cotton than the untreated check. Cotton treated with the ULV applications yielded more than that treated by conventional EC applications. Gas chromatographic analysis of residue samples has been initiated.

SUPPORTED BY U.S. Dept. of Agriculture

4.0002, ENGINEERING SYSTEMS FOR COTTON PRODUCTION
W.T. DUMAS, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA00297)

OBJECTIVE: Develop or improve cotton production subsystems, while simultaneously providing information and data for a computer simulation model.

APPROACH: Determine the optimum number and arrangement of nozzles per row and the optimum volume of spray solution required for most efficient application and utilization of agricultural chemicals. Measurements will be made of penetration, distribution and drift by the use of dyes, fluorescent tracers, chemically sensitive cards and by plant response.

PROGRESS: See regional project S-69 progress report.

SUPPORTED BY U.S. Dept. of Agriculture

4.0003, EFFECT OF HERBICIDES ON AN AQUATIC ENVIRONMENT
H.H. FUNDERBURK, Auburn University, School of Agriculture, *Auburn, Alabama* 36830

The following studies will be undertaken: Absorption, translocation, and distribution of a xylem mobile herbicide (fluometuron) in Eurasian milfoil; effect of diquat, paraquat, fluometuron, dichlobenil, and at least 1 additional promising aquatic herbicide on certain metabolic processes of aquatic plants; degradation of diquat and 2,4-DBEE in an aquatic environment (water, plants, soil and fish); effect of promising aquatic herbicide on fish.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

4.0004, EFFECT OF HERBICIDES ON AN AQUATIC ENVIRONMENT
H.H. FUNDERBURK, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA-05-0003)

OBJECTIVE: Study absorption, translocation, and distribution of a phloem mobile herbicide (2,4-D) and a xylem mobile herbicide (simazine) in Eurasian milfoil. Study the effect of diquat, paraquat, simazine, dichlobenil, and at least 1 additional promising aquatic herbicide on certain metabolic processes of aquatic plants. Study the degradation of diquat, simazine, and 2,4-D in an aquatic environment (water, plants, soil and fish). Determine the effect of promising aquatic herbicides on fish.

APPROACH: Labeled and non-labeled compounds will be used in laboratory, growth chamber and field experiments. Analysis will use several chromatography methods, qualitative and quantitive chemical analysis, autoradiography and spectroscopy.

PROGRESS: Degradation of 2,4-DBEE was rapid usually within 24 hours to 2,4-D in all systems containing living organisms. The main degradation products were CO(2) and a complex of 2,4-D and an unknown molecule. Degradation was greatest in carboxyl carbon label and least in ring labeled 2,4-D. Absorption and translocation by watermilfoil was greatest with the ester apparently aiding in absorption to structure of the side chain. All plants contained only 2,4-D which was readily translocated acropetally and basipetally as well as leaked out of the non-treated root and shoot. Degradation by UV light may be a factor in degradation of the ester, with 50% degradation in 12 hours to 2,4-D. Degradation of 2,4-D under the conditions of the experiment was not a large amount. The ester apparently hydrolyzed in water solution since 2,4-DBEE steadily broke down to 2,4-D under such conditions. The effect of 2,4-DBEE on watermilfoil was readily observable, since only 0.029 ppm killed witnin 14 days indicating the small amount needed for such results.

4.0005, PRELIMINARY STUDIES ON ENDRIN AND OTHER PESTICIDE UPTAKES BY FINGERLING CHANNEL CATFISH
R.L. ARGYLE, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Marion, Alabama* 36756

Pesticides have been found in the flesh of channel catfish raised for sport and food, and in some instances these chemicals

have been attributed to seriously injuring or even killing fingerling and large fish. Pesticides that contaminate these fish can come from the water supply, soil, feed, and air (wind borne). Studies will be conducted in pools and aquariums to determine the effect that each pesticide source has on the fish. By conducting these studies in pools and aquariums using pesticide-free water, by feeding purified diets, and by using known amounts of the pure form of pesticide, variables and interactions may be avoided that complicate data interpretations. Thus, these findings may be used in designing studies in near-natural situations and interpreting the results.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0006, UPTAKE AND RELEASE OF DALAPON IN EARTHEN PONDS

R.L. ARGYLE, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Marion, Alabama* 36756

Objectives: To quantitate the uptake and release of Dalapon in water, fish, soil and plants in earthen ponds.

Procedure: Twelve 0.1 acre earthen ponds will be filled with water and 'sprigged' with cattail plants. After a short period of acclimation, fingerling channel catfish, bluegill sunfish and largemouth bass will be stocked into each pond. Dalapon at 0 and 1/3, and 3 times the recommended amounts will be applied to all ponds. Samples of water, fish, soil, and vegetation will be taken at 0,1,3,7,14, 28, and at each 28th day thereafter until no Dalapon can be detected or the amounts found are stabilized.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

4.0007, CONTROL METHODS FOR JUNIPERS, SHRUB LIVE OAK, AND ASSOCIATED WEEDS

T.N. JOHNSEN, U.S. Dept. of Agriculture, Crops Research Division, *Flagstaff, Arizona* 86003 (0710-04-02)

OBJECTIVE: To develop and evaluate control methods for use on junipers, shrub live oak, and associated species as part of a broad national program to develop principles and practices on control of weeds and brush under various climatic conditions.

APPROACH: Studies include field, laboratory and greenhouse experiments on methods of controlling brush and weed species that are problems on grazing lands and will include studies of herbicides and their ecological, physiological and agronomical aspects as they affect rangeland brush and weed populations and the resulting ecological impact on desirable vegetation. Studies include some aspects of fate of herbicides when applied to watershed areas.

PROGRESS: Picloram injected into a small stream at the rate of 5 ppmw for 50 minutes had downstream picloram concentration peaks of 2.5 ppm at 1/4 mile, 0.9 ppm at 1/2 mile, 0.34 ppm at 1 mile, 0.01 at 2 miles, 0.002 ppm at 4 miles and not detectable at collection points further downstream. Picloram was not detectable from water and soil samples collected downstream of the injection point after 48 hours and during the remainder of 1969. Broadcast burning of chaparral vegetation 2 months after aerial spray treatment reduced the soil picloram content from 1.1 to 0.2 lb/A. Unburned plots had little or no change in picloram content during the same time interval. Damage on vegetation indicated m-(3,3-dimethylureido)phenyl-tert-butylcarbamate has moved as much as 200 feet off of 1/10 acre-sized plots treated with a granule formulation on clay soils. Evidence of herbicide movement from spot applications of this herbicide were less. The herbicide effectively controls shrub live oak, gambel oak and Utah juniper at 4 to 8 lb/A, broadcast on the soil.

SUPPORTED BY U.S. Dept. of Agriculture

4.0008, PESTICIDE APPLICATION EQUIPMENT IN RELATION TO DRIFT OF PESTICIDES AND PEST CONTROL

K.R. FROST, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-2014-4155-028)

OBJECTIVE: Evaluate existing ground and air application machinery in relation to pesticide drift; modify equipment and practices to reduce drift of pesticides; develop new equipment and management practices to reduce drift and give effective pest control; and evaluate for effectiveness of insect control.

APPROACH: Present methods and equipment of applying pesticides will be evaluated to determine drift and effectiveness. Tests will be made in the field using two methods or variations in equipment. Changes will be made to improve results and new equipment developed for the same purpose. Both airplane and ground application will be made to compare results.

PROGRESS: Aerial drift tests were run August 4, 1969 on alfalfa 8 miles south of Coolidge, Arizona. Three runs were made in the afternoon using different materials simultaneously with 2 airplanes in 2 fields end to end. The usual data for drift tests, temperature at 32 ft and 8 ft, relative humidity at 1 ft and 5 ft levels and wind velocity at 8 ft were recorded before, during, and after applications were made. Drift collection determination and analysis is not complete for this series. Analyses of the aerial tests run in 1968 using fluorescent dye and thickener were completed and a manuscript prepared. These tests were run using 50 gallons of emulsion spray containing 20 lb of methoxychlor, and 1 lb of brilliant sulpho-flavine (BSF). In addition some applications included thickener and the remaining served as controls. The Cascade impactor sampler collected less drift at most stations downwind for both molasses and dacagin added as thickeners. Results were not conclusive and tests should be run again before use of thickeners is recommended for reducing drift. The BSF fluorescent dye gave interpretive results closely correlated with usual processing of drift on glass plates and represent only 10% of the effort.

SUPPORTED BY U.S. Dept. of Agriculture

4.0009, PESTICIDE APPLICATION EQUIPMENT IN RELATION TO DRIFT OF PESTICIDE AND PEST CONTROL

G.W. WARE, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-2014-4161-028)

OBJECTIVE: Evaluate existing ground and air application machinery in relation to pesticide drift. Modify equipment and practices to reduce drift of pesticides. Develop new equipment and management practices which will reduce drift and give effective pest control. When equipment for drift safe application has been developed, it will be evaluated for effectiveness of insect control.

APPROACH: Present methods and equipment of applying pesticides will be evaluated to determine drift and effectiveness. Tests will be made in the field using two methods or variations in equipment. Changes will be made to improve results and new equipment developed for the same purpose. Both airplane and ground application will be made to compare results.

PROGRESS: Spray thickeners and a fluorescent dye were added to aerial applications of methoxychlor made to a 10-acre plot of alfalfa. Dacagin at 0.8%, blackstrap molasses at 24-25% and Cab-O-Sil at 3.5% were each compared with an unthickened control emulsion, and all three resulted in an apparent reduction in drift. Based on cost, molasses would be the most economical additive. Using a fluorescent dye as an indicator is a much faster method for measuring deposits than gas chromatography. 1969 drift studies indicated that only 40% of an aerial spray application reaches the target when applied from a Piper Pawnee, 3:00 PM, 2 MPH winds, RH varying from 45% at 2 ft to 29% at 33 ft, and 105 F. Previous on-target samplings indicate an average of less than 40% reaches the target crop.

SUPPORTED BY U.S. Dept. of Agriculture

4.0010, BIOLOGY AND CONTROL OF INSECTS AFFECTING COTTON IN ARIZONA

T.F. WATSON, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-2014-4161-013)

OBJECTIVE: Determine habitats of insect pests, identify parasites and predators and study factors affecting insect pest activity. Investigate life histories of insect pests. Evaluate toxicological and residual properties of chemicals of value in control. Establish criteria for timing pesticide applications and determine effects of insect injury on quality and marketability of cotton.

APPROACH: Determine winter survival of pink bollworms (cage studies). Large plot study of timing and number of insecti-

cide applications on destructive and beneficial insects. Through use of insecticides determine percent of damage caused by various insects. Find insecticides to eliminate 'drift residue problems' from cotton to alfalfa.

PROGRESS: A test was conducted to compare the effectiveness of carbaryl and carbaryl plus molasses, each applied at 3-gal. and 5-gal. total solution rates, against the pink bollworm. Results indicated no difference in using either of the solution rates and no significant advantage to control by adding molasses to carbaryl. An evaluation of 11 acaricides against the spider mite, Tetranychus turkestani, showed that Azodrin, Acaralate, Chlorobenzilate and Galecron effectively controlled this mite. Seven insecticides were compared for control of a late-season infestation of Heliothis zea on cotton. None of the treatments resulted in significant yield increases. A test comparing Azodrin, Bidrin and Dylox for control of lygus in cotton resulted in yield increases, with only the Azodrin treatment being significantly higher. Another experiment was designed to control lygus at three square-damage levels. Bidrin was applied when square damage reached 5, 15, and 25 per cent in the respective treatments. No significant differences were obtained in yields among the treatments, including untreated checks. An experiment was conducted to determine the need for control of late-season pink bollworm infestations in cotton. Treatments consisted of plots receiving none, 2, 3 or 4 applications of toxephene methyl parathion on a 6 to 7 day schedule after the infestation reached 10 per cent. Results indicated that there was no advantage to applying late-season control measures.

SUPPORTED BY U.S. Dept. of Agriculture

4.0011, EFFICIENCY AND HAZARDS OF RESIDUAL HERBICIDES IN SOILS UNDER IRRIGATION.
K.H. BOWMER, Comm. Sci. & Indus. Res. Org., *Griffith, New South Wales, Australia*

Object: 1. Atrazine, diuron, fluometuron, trifluralin herbicides. a) Investigate possible hazards of over persistent residues to crops intense rotations (rice, cereals, sorghum, maize, sunflower, soyabean, safflower, cotton). b) Investigate possible hazards of over persistent residues to crops intense rotations (rice, cereals, sorghum, maize, sunflower, soyabean, safflower, cotton). b) Investigate instances of inefficient weed control. c) Investigate less persistent alternatives e.g. thiolcarbamates. 2. Investigate fate of bromacialherbicide in citrus orchard soil.

Approach: Initially, atrazine and bromacil. Monitor residues in soil where history of application is well-documented. Field studies of atrazine activity and persistence under maize. Laboratory studies with contrasting soil types of adsorption, leaching, persistence of herbicides. Effects of clays, organic matter, pH, temperature and water content on rate and pathway of breakdown.

SUPPORTED BY Australian Government

4.0012, DEPOSIT AND DRIFT OF PESTICIDE CHEMICALS
N.B. AKESSON, Univ. of California, School of Agriculture, *Davis, California* 95616

An increased effort will be directed toward the total spray budget concept by 1) fitting past run data into the developing computer model program and 2) by concentrating more specifically on field studies to collect first the spray swath and downwind ballistic fallout pattern to 1000 feet; and second, the airborne or transport pattern from 1000 feet to 5-8 miles. By directing our effort or concentration into two stages the ballistic fallout and the air transport, we hope to increase our sensitivity and accuracy sufficiently to obtain significant correlation and prediction (by means of the statistical model) results. This increases our use of the atmospheric diffusion data as well and will help to develop a significant correlation between downwind transport and diffusion parameters. Some preliminary investigations have indicated that virtual temperature, which combines the effects of temperature and humidity, should be considered in our studies of atmospheric stability as it relates to drift and deposit of pesticides. Data taken this past year will be evaluated for the possible correlation of this parameter and if proven valid will be used in future experiments.

Statistical computer studies have been made on field data of the past to determine, by regression analysis, the functional relationship between drift-deposit level and distance downwind including the application area. More detailed program analysis including extension of the air transport and diffusion model will be used to obtain more complete data for a total spray budget analysis.

The overall objective remains the reduction of airborne pesticide chemical transport to enable safer and lowered levels of pesticide use.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

4.0013, CONTROL OF WEEDS AND CERTAIN OTHER AQUATIC PESTS IN THE PACIFIC SOUTHWEST
R.R. YEO, Univ. of California, Agricultural Experiment Sta., *Davis, California* 95616 (0710-02-01)

OBJECTIVE: Develop new or improved chemical, biological, and other methods for controlling weeds, Asiatic clams, and certain other aquatic pests in canals, lakes, reservoirs, and other aquatic situations. Determine the fate of herbicides, molluscicides, and other chemicals used in aquatic situations.

APPROACH: Search for and/or evaluate new and promising aquatic herbicides in greenhouse aquaria and flowing canals, outdoor pools, and closed system canals and in field canals and reservoirs. Conduct life history and ecological studies. Make samplings and analyses to determine the persistence of herbicides and molluscicides in water in natural canals and reservoirs and in small pools under controlled conditions. Evaluate fish, competitive plants, and other agents for biocontrol of aquatic weeds and other aquatic pests.

PROGRESS: Three acetals of acrolein were found to control submersed aquatic weeds in 2 canals for 6 mi at 7.5 to 10 ppm with 4 and 8 hr exposure. The hydrolysis of allylidiene diacetate to acrolein in 2 canals in which aquatic weeds were controlled peaked 2 mi downstream after 8 hrs with water at 19 C and 1 mi downstream after 2 hrs with water at 14.5 C. Acrolein applied at 4 ppm for 4 hrs plus a booster of 2 ppm for 3 hrs dissipated to .1 ppm after 32 mi. Diquat plus copper sulfate at .15 ppm controlled several aquatic weeds in reservoirs. Simazine, chloroxuron, copper metal, copper nitrate, igran, and diuron at 1, .5, 40, 4, .5, and .5 ppm, respectively, controlled Chara and Cladophora in growth pools without harming fish. Copper ion residue studies showed it to dissipate (in decreasing order) to non-detectable amounts fastest with copper nitrate - copper sulfate - cuprose citrate - and copper metal. Copper sulfate circulated continuously with fresh weekly increments of 0.0, .1, 1. and 10 ppm of copper ion in aluminum irrigation pipe for 25 weeks did not seriously corrode the pipe. Slender spikerush was found highly effective in controlling aquatic weeds by competition in two irrigation canals.

SUPPORTED BY U.S. Dept. of Agriculture

4.0014, INVESTIGATIONS OF RESIDUES IN WATER AND CROPS IRRIGATED WITH WATER CONTAINING HERBICIDES
F.L. TIMMONS, Stanford Research Institute, *Menlo Park, California* 94025 (0710-02-10(C))

OBJECTIVE: Determine the presence and concentrations of selected herbicides and degradation compounds and metabolites in water, soil, and in greenhouse-grown crops irrigated with water containing known concentrations of each herbicide.

APPROACH: Potatoes, carrots, onions, tomatoes, romaine lettuce, soybeans and milo will be grown to maturity in the greenhouse. Amitrole-T, 2,4-D, dalapon, silvex, dichlobenil, diuron, and simazine will each be applied to two concentrations to irrigation water to be applied by overhead sprinkle and bottom flooding methods to each crop at an early fruiting vs. late fruiting stage. Samples of treated water will be taken at time of irrigation and samples of the soil will be taken a few days later. Samples of edible portions of treated crops will be taken at maturity. All samples will be analyzed by appropriate methods to determine concentrations of each herbicide and of important metabolites. Diquat and endothall may be substituted for diuron and simazine.

PROGRESS: All six crops have been grown, irrigated with treated water, and samples of edible parts taken at normal harvest

time and processed for analyses. Analyses were completed for silvex, 2,4rD, dalapon, and amitrole. Average maximum concentrations (ppm) of 2,4-D residues found in the various crops irrigated with water containing the highest concentration were as follows: potatoes, 0.03 to 0.12; milo, 0 to 0.12; carrots, 0.02 to 0.06; soybeans, none; leaf lettuce, 0.11 to 0.33; onions, all below 0.05. Residues of silvex (ppm) from the highest concentrations of silvex in treated water were: potatoes, 0.03 to 0.3; milo, none; soybeans, 0.09 to 0.17; carrots, none; lettuce, none; onions, none. The residues of dalapon (ppm) from the highest concentration were: potatoes, 0.04 to 2.7; milo, 0.05 to 0.53; soybeans, 0.6 to 1.9; carrots, 0 to 0.81; lettuce, 0.05 to 1.13. No amitrole residues were found in any crop except the 0.09 ppm in milo grain from sprinkler irrigation with water containing 0.44 ppm of amitrole. The highest concentration of each herbicide was much greater than those found after normal applications for weed control. Maximum residues of dalapon or 2,4-D found in any crop were much lower than FDA tolerances on several food crops.

4.0015, NAVY ENVIRONMENT - BIOLOGICAL DEGRADATION OF PESTICIDES IN THE MARINE ENVIRONMENT

H.P. VIND, U.S. Navy, Civil Engineering Lab., *Port Hueneme, California*

Technical Objective: The Department of the Navy is responsible for all pesticides and herbicides it uses. This responsibility includes pesticides and herbicide waste-products which find their way into the marine environment. This effort is directed toward finding means of enhancing the biological degradation of pesticides in order to reduce their adverse effects upon the marine environment and to reduce pollution.

SUPPORTED BY U.S. Dept. of Defense - Navy

4.0016, ANALYTICAL METHODS FOR PESTICIDES IN SOIL AND WATER

F.A. GUNTHER, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-SSE-2407)

OBJECTIVE: Develop dependable, quantitative extraction procedures for removing pesticide residues from samples of water. Develop methods of analysis that will identify and measure the pesticides present, and that are sufficiently sensitive to permit the use of smaller samples than are now required. Automate the analytical procedures as far as practical to achieve maximum output per man-hour.

APPROACH: Carbon columns and other adsorbing media will be investigated, as well as counter-current partitioning procedures. Analytical methods, and particularly instrumental methods that are susceptible to automation, will be developed and adapted to use for water and soil analysis.

PROGRESS: An automated procedure to determine triazine herbicides in soil was developed and a publication is in preparation. The soil sample is introduced into the machine without any preliminary treatment, an important breakthrough for this type of analysis. A similar procedure for determining DDT in soil is approaching completion. A means for distinguishing between DDT and polychlorinated biphenyls was developed and tested on animal tissue samples. There is a striking dissimilarity in responses of the two types of compounds and the method appears a much-needed means for removing doubts about the presence or absence of DDT. Specialized apparatus for extracting pesticides from water was constructed for use in this particular research.

SUPPORTED BY California State Government - Sacramento

4.0017, PHYSIOLOGY, BIOCHEMISTRY AND CONTROL OF AQUATIC WEEDS, CHEMISTRY OF HERBICIDES

P.A. FRANK, U.S. Dept. of Agriculture, Crops Research Division, *Denver, Colorado* (0710-02402)

OBJECTIVE: Improve existing methods available for the control of submersed aquatic weeds, and develop information which may ultimately lead to the use of new and more effective weed control principles and practices. Improve and develop chemical procedures for analysis of herbicides, determine the residues resulting from their use in and near water, and provide data which will facilitate registration and use of the the materials as aquatic-weed herbicides.

APPROACH: Conduct an evaluation program to determine the herbicidal activity and potential usefulness of new herbicides and experimental materials. Arrange preliminary field trials of promising materials. Study absorption and translocation of herbicides and developmental physiology of representative weed species. Treat canals, ponds, and ditchbanks; collect soil and water samples for residue and degradation studies.

PROGRESS: Dissipation of 2,4-D dimethylamine at 133 and 254 ppb in irrigation water, was linear for distances of 6 and 7 mi of water flow. Residues were reduced more rapidly than for other water soluble herbicides tested. Dye used as a model of herbicide dissipation indicated dye cloud elongation rates of 12 to 18 minutes per mile. Reductions in maximum dye concentration between the 0.25 mile and 8 mile stations were 74, 47, and 32% for the 2500, 4400, and 6600 ft treatments, respectively. Studies on dissipation of xylene in irrigation water showed that treatment rates of 550 to 600 ppm were reduced as rapidly as 92% after 4 mi of water flow in 1 canal, to as little at 77% after 10 mi of flow in another canal. Bluegill and trout were killed by the xylene 9 and 10 mi downstream from the treatment sites. Spring time soil samples from ditchbanks treated in the fall with 70 lb per A TCA had residues of 1 to 44 ppm in the surface inch, and 1.3 to 10 ppm in the 2 to 4 inch soil layer. Very low and transitory levels of TCA occurred in water the next spring. Established that loss of the PGBE ester from water is due largely to loss of emulsion with the ester settling to the soil surface. After 4 and 12 hr, loss of silvex from water was 83 and 91%, respectively. Containers of glass, polyvinyl chloride (PVC), high and low density polyethylene (HDP, LDP) were adequate for storing TCA and diquat. BEE of 2,4-D stored well in all but LDP. Only glass and PVC were suitable for storing dichlobenil.

SUPPORTED BY U.S. Dept. of Agriculture

4.0018, HERBICIDE RESIDUES

T.R. BARTLEY, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

It is important to know the level of herbicide that gets into irrigation water either through direct application to the water or through applications adjacent to the water. The amount of herbicide that accumulates in the aquatic plants and the aquatic and agricultural soils is also pertinent to a better understand and use of the weed control method being practiced.

Samples of water and sometimes aquatic plants, aquatic soils, and agricultural soils exposed to herbicide treatments are collected in and along irrigation canals for analysis of various herbicides commonly used for weed control on irrigation projects.

Herbicides such as 2,4-D, 2,4,5-T, xylene and acrolein copper, are being emphasized in this study. The level of herbicide present in samples will be measured through the use of gas chromatographic and atomic absorption spectrophotometric techniques.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

4.0019, PESTICIDE MOBILITY AND DEGRADATION IN SOIL-WATER SYSTEMS

K.G. DOXTADER, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00242)

OBJECTIVE: Identify the principal degradation products and determine the mechanisms and kinetics of pesticide transformations in soil-water systems.

APPROACH: Pesticides will be incubated with soils of varying chemical, physical, and mineralogical composition. Studies will be made of the influence of temperature, light, aeration, added organic matter, and moisture on pesticide decomposition in these soils. Degradation will also be followed in soil-water suspensions and in columns of soils perfused with pesticide solution. Efforts will be made to determine the kinetics of herbicide decomposition and to identify and characterize major degradation products as well as to isolate the microorganisms responsible for the degradation process. Initial emphasis will be placed on stu-

dying the degradation of three herbicides: 2,4- dichlorophenoxyacetic acid (2,4-D), 2,4,5-trichlorophenoxyacetic acid (2,4,5-T), and picloram (Tordon).

PROGRESS: Rates of decomposition of the herbicides pyrazon and diuron were measured in three different soils. Diuron was found to be extremely persistent in these soils; only very slight degradation was observed over an incubation period of 35 weeks. Significant pyrazon decomposition occurred in these same soils in less than one month. Evidence was obtained which indicated that microorganisms play a major role in the decomposition of pyrazon. In a sterilized soil, the concentration of the herbicide remained nearly constant over a period of several weeks. With the same soil under non-sterile conditions, appreciable pyrazon decomposition was observed. Four different bacterial types isolated from soil by an elective culture technique were found to be capable of degrading the herbicide in pure culture.

4.0020, THE PHYSIOLOGY AND CHEMICAL CONTROL OF AQUATIC WEEDS IN THE SOUTHEAST

L.W. WELDON, U.S. Dept. of Agriculture, Crops Research Division, *Fort Lauderdale, Florida* 33310 (0710-02-03)

OBJECTIVE: Develop methods of controlling aquatic vegetation in waterways, canals, lakes, ponds, and irrigation systems.

APPROACH: Evaluate new chemicals and additives to herbicides to increase effectiveness on elodea, Eurasian watermilfoil, water hyacinth, alligatorweed, and other aquatic plants. Study life cycle of the plants and environmental factors affecting the carbohydrate reserves, plant response to herbicides, and persistence of herbicides in the water, plant, organism, and hydrosoil.

PROGRESS: Ametryne (3 lb/A) applied in combination with 2,4-D (1/8 lb/A) controlled water hyacinth. A granular and slow release pellet of the amine salt of endothall have controlled hydrilla in lakes. The slow release pellet has given longer control in lakes and flowing canals. Cost of control and fish toxicity have been reduced when using slow release pellets. A weighted formulation of the amine salt of endothall has controlled hydrilla in flowing canals. Diquat, endothall, and copper sulfate have been encapsulated into a slow release capsule. Plastic enclosures (25 sq. ft.) have proven to be an excellent research tool for evaluating herbicides on submersed aquatic weeds.

4.0023, EFFECTS OF PESTICIDES ON ESTUARINE PRODUCTIVITY

T.S. HOPKINS, Univ. of West Florida, Graduate School, *Pensacola, Florida*

The campus of The University of West Florida is located on the west side at the head of Escambia Bay, a commercially important estuary for the production of oysters, shrimp, and fish. Part of the drainage basin of this estuary, including an embayment or bayou and small stream lies on University property that has been dedicated as a natural conservation area and will remain undeveloped.

The Faculty of the Department of Biology and Marine Sciences plans to initiate a continuing study of this habitat to determine the ecological relationship. Concurrently, a similar habitat on the east side of the bay that is not protected from man's encroachment will be studied in comparative detail to determine the effects of pollution. It is anticipated that the program will serve as a training program for graduate students in the field of marine biology.

An initial 12-month program is proposed that has the following objectives: 1. A physical, chemical, and biological inventory of the two bayous adequate to provide an understanding of the resident plant and animal communities; and, 2. An analysis of migratory fauna and their 'input' into the ecosystem; and, 3. A periodic surveillance project will monitor the water, bottom deposits and biota for pesticide residues. (These are anticipated because of the routine use of these chemicals in the drainage basin).

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

4.0024, PESTICIDE KINETICS

C.W. MILLER, U.S. Dept. of the Interior, Bureau of Commercial Fisheries, *Sabine Island, Florida* 32561

Investigate, under field conditions, the occurrence and distribution of insecticides in tidal areas associated with an estuary. Samples of water, soil and selected biota will be collected immediately prior to application of the test material to establish a base line indicative of previous commercial treatments. The persistence, localization and possible degradation of the test chemicals will be followed.

4.0025, RELATIONSHIPS BETWEEN PESTICIDES AND GEORGIA FARM POND ECOSYSTEMS

M.T. HUISH, Univ. of Georgia, Agricultural Experiment Sta., *Athens, Georgia* 30601 (GEO00392)

OBJECTIVE: Study is to provide answers to problems of the relationship of pesticides and farm pond ecosystems.

APPROACH: Most of Georgia's farm ponds are constructed on piedmont clay or sand. These two major soil types will be employed in the experimental design which will test Dieldrin and Lindane. Known concentrations of the pesticides will be introduced into fiberglass containers and the resulting concentrations in the two soil types, of flowing and nonflowing water systems, as well as concentrations contained in fishes and plants will be determined by use of gas chromatographic methods.

PROGRESS: During the report period the results of the first phase of the project were compiled in the form of a PhD thesis, 'Magnitude and Distribution of Insecticide Residues in Artificial Ecosystems and in a Farm Pond', by Wendell Joseph Lorio. The study will continue with another student, and will consist of pesticide applications to additional series of aquatic systems. The previous work on this project consisted of applying two pesticides (Lindane and Dieldrin) to three series of aquatic systems each of which included twelve forty-liter containers having selected soils, aquatic plants and fish. Water was static in 50% of the systems and flowing in the others. The pesticides were introduced at concentrations sublethal to the fish used. Samples of each component of the systems (fish, plant, soil and water) were taken. These were

then subjected to standard extractive techniques to recover the Lindane and Dieldrin residues. Gas chromatographic methods were employed.
